Why do we find glossy overweight scientific periodicals in many languages on such subjects as leprosy, syphilis, and balneology? There are world conferences on these subjects, patronized by dignified delegates and internationally financed. Why are the journals that refer to health education, welfare, and the social-economic aspects of medicine relatively few, unassuming, and amateurish? Why is it that these subjects are so seldom celebrated by meetings and by discussions? We take our own standards of life so much for granted that we simply have no conception that they are not universal. Sometimes our patients give up talking to us because they know that we will never understand. We allow children's hospitals to exclude women from their staffs, although these hospitals are largely supported by public funds, and although the women who conduct the welfare clinics are the doctors who above all would profit by the paediatric experience.

All over the world one sees those dreadful anomalies: the sanitary inspector's child with profound helminthiasis, the doctor's child with severe malnutrition, and the school teacher's child whose regime alternates between that dictated by the local witchcraft and that proclaimed by the more flamboyant advertisements for patent foods and patent medicines.

The Project

The crying necessity to-day is for the application of some of the most obvious and most desirable improvements. Up to now the acknowledged leaders of medicine have been mostly super-chemists, super-carpenters, and super-sanitary inspectors. Medical, social, and economic welfare can no longer afford to be directed by the whims of the influential ignoramus.

There is a certain town where the welfare centres are conducted on scientific lines by a well-trained medical staff. Patients are weighed and measured at each attendance. Dick, Schick, Wassermann, and Mantoux each receive obeisance. Charts and records are admirably kept. But the infant mortality has remained completely unaffected. The doctors say to each other, "This is interesting work, but it does no good." In another town a few miles away the welfare centres are run entirely by nurses. Here they teach the mothers what to eat and what to give the children to eat. They go to the houses and see exactly what is boiling in the pot. They make a fetish of breast-feeding. They teach the mothers how and why the babies should be washed and clothed and aired. The infant mortality has been reduced in such a dramatic manner that two doctors were spending most of their time in trying to explain it away.

The pioneer paediatricians had one quality in common. They regarded the parents, and the mother in particular, as the prime enemies of the child. In these more enlightened and infinitely more complicated days it is beginning to be realized that to take a child into hospital and cure his disease only to send him back to precisely those conditions which produced the disease is a form of hypocrisy as well as being no sort of economy. It is also realized that the love of children is not a sentimental virtue. It is a natural function. It can be relied upon, and with foresight and intelligence and perseverance it can be educated into the most powerful disease-preventing factor on the face of the earth, and it is one that can be found all over the earth.

Those responsible for public health programmes are bound in loyalty to their public to examine work that has been done in other countries and to sift out methods that are applicable. But many health officers, together with certain politicians of the nationalist-racial-prejudice variety, often claim the right to "make their own mistakes," "to get along somehow by a process of trial and error" at whatever cost to the unfortunate, the impoverished, and the inarticulate. It would be salutary discipline for politicians and public health authorities if they, like clinicians, had to sign the death certificates of all their failures. It is therefore essential for those who direct medical policy to study not only the oecology of disease but also the varieties of approach, of administration, and of treatment that are attempted in various countries, and to cultivate the habit of appraising them.

Nationalism and racial torts have done so much damage to the amiabilities of civilization and to the advance of social improvements that we must do what we can to extract some advantages from them. Their methods of education and of propaganda are among the most successful that are known. They include education and discipline of the very young, keeping people busy, giving them responsibility, making them feel that they are indispensable to their ideal: these are the main approaches. Through the amalgamation of welfare, education, agricultural, administrative, and health services these methods might be employed to build up an ideal State.

All over the world the problem is the same—to increase social service of every variety within the economic possibilities of the population. Some countries (such as Yugoslavia, for example) have been doing this with marked success. British tradition in nursing and medicine is old and well established, and accordingly slow in adapting itself to new-found needs and new-found objectives.

A Neglected Branch of Medicine

Welfare work is the youngest, most unassuming, most neglected branch of medicine. Instead of being the foundation of all good medicine it is regarded as a merely tolerated excrescence. Even its stoutest supporters make nothing but tentative and apologetic claims for it. Though there is work crying out to be done, it is always being warned that it must not "usurp" this and that. It has suffered from all manner of handicaps. It has often been conducted by inexperienced and undistinguished doctors. "Sanitary-engineers" are supposed to have some specialized knowledge of sanitation, but child-welfare doctors are seldom required to have any specialized knowledge of paediatrics. It has only rarely been associated with any sort of research, and in consequence has often lacked vitality and pursued antiquated or unsuitable methods. Welfare centres are established in various countries on conventional lines long before local conditions have been studied and local needs understood. And the creature that in all the world is most at the mercy of his environment is the human child.

Welfare work has often been regarded with jealous disfavour by general practitioners, scoffed at by hospital staffs, dominated by ignorant lay committees. It is often directed by health officers who, in the absence of any clinical or practical experience, are prepared to dictate policy, very often to the serious detriment of the work.

Because of the lack of skilled direction welfare work is often pursued half-heartedly. Even in a country which is a by-word of advancement in these matters one finds the most strange situations.

The public health nurse was visiting the house of a labourer getting the equivalent of £4 a week and presenting the mother with clothes for the expected infant. Two older children appeared, suffering from dirt and dermatitis. They were treated with ointments. It was discovered that the family kept a car. A visitor expressed surprise at the necessity for giving away clothes to people who were obviously well off and at the absence of comment on the obvious dirt and disorder. The public health nurse explained that she could not comment on the dirt or the people might be offended; they were too poor to buy infant clothes, because they had to keep a car in order to go to the races.

In spite of the fact that welfare work is often cramped for funds, for staff, for space, and for honest objective, it is undoubtedly the method by which improvement can in future most economically be made. To anyone who has had first-hand experience of welfare work, in its wider sense, when conducted in close co-operation with paediatrics, obstetrics, and other social services, it is obvious beyond all doubt that the extension and development of this work are the most effective and most economical means by which the greatly-to-be-desired improvement in health and in living can be realized.

Planned Economy and Personnel

It is more profitable to spend money on 100 semi-healthy children so that they may become 100 healthy citizens rather than on ten middle-aged invalids so that they may become ten old semi-invalids. And, incidentally, it is much cheaper. It is essential in the first place to give reorientation to medical education that will fit the doctors for a more constructive function. Paediatrics, especially preventive paediatrics, calls for more research and for far more application. In the second place the training of nurses will have to be revised to make them fit for work that is preventive as well as curative. Medicine must realize its social as well as its somatic obligations. The work of the almoner and of the social worker must be incorporated in the essential work of the medical personnel.

The kind of rigidity and automatism that obtains in some nurses' training is entirely out of place in welfare work. A training lasting not more than three years should be developed that will include preventive, curative, social, educational, environmental, nutritional, mental, domestic, and even agricultural, economic, and industrial considerations, especially with regard to children. Courses of training in Canada and Yugoslavia, methods of conducting health work from Kentucky to Batavia, should be considered in evolving new developments. Preventive and curative work are so intimately connected in their application to individuals (as contrasted with their application to communities and to things) that effective medical services will not be attained until their present unhappy separation has been healed.

Sound welfare work can only be accomplished on a good basis of paediatrics and obstetrics, with the emphasis on the paediatrics. In countries that are impoverished and backward it is the extension of welfare work that offers the best hope of improved standards of living. Welfare cannot be developed satisfactorily until it forms the basis of a wide and well-planned State organization. It is high time for some fairy godmother to put in an appearance and place this most deserving of all Cinderellas in her proper sphere.

I have to thank the Honorary Director of Medical Services, Straits Settlements, for permission to publish.

GLYCERIN AND IODINE IN TREATMENT OF WOUNDS

In response to inquiries that have come from readers of his paper on the reception and treatment of air-raid casualties (April 19, p. 584) Mr. John Robert Lee sends the following fuller note on the use of glycerin and iodine.

The formula of the glycerin and iodine solution is:

℞ Iodine .. .. grains 200
Potassium iodide .. .. .. ʒj and grains 160
Distilled water .. .. .. ʒj
Glycerin .. .. .. to ʒxx

Make a solution. To be used as directed.

Dispensing Note.—Grind the potassium iodide to a fine powder in a mortar, add the iodine, mix well with a glass rod, add the water, which just makes a solution, then add the glycerin.

Technique.—This solution may be used in full strength or in half strength, being diluted with glycerin. Use the solution *—full strength—to paint on abrasions, or to pour into wounds* if need be while resuscitation is being undertaken; also in the theatre to swab out or to "curette" with gauze soaked in the solution such wounds as cannot be excised. So far as possible bandages are not used, the wounds being painted and covered with a sterile towel. At the first dressing in the ward, in cases in which dressings have been used, syringe hydrogen peroxide on to the edges of any adherent gauze or wool to facilitate removal; then use half-strength solution, because in some cases the full strength causes some smarting pain. Pour on the solution or paint the parts lightly; do not rub. Dilute to half strength by using equal parts of the solution and *glycerin; never use water:* water will cause burning and blistering. The solution, strong or dilute, will not burn or blister.

CENTRAL MEDICAL SCHOOL, FIJI

Steady progress in the fight against disease is being achieved among the Western Pacific Islands by native medical practitioners trained at the Central Medical School, Suva, Fiji, of which Dr. D. W. Hoodless is the principal. It is hoped that this school may eventually become the recognized medical training centre for the entire Pacific Islands area.

Founded by the Government of Fiji as an integral part of the Native Medical Practitioner Service, the Suva Medical School became the Central Medical School in 1928; when it was enlarged and extended. This was made possible by assistance from the Government of Fiji and the International Health Division of the Rockefeller Foundation. Students come to the school from the Colony of Fiji, Western Samoa, the British Solomon Islands Protectorate, the Gilbert and Ellice Islands, Nauru, the Kingdom of Tonga, the Cook Islands, the Rotuma Dependency, the Anglo-French Condominium of the New Hebrides, and American Samoa. It is hoped to bring Pitcairn Island within the scope of the school's activities. The course of training extends over four years, the first six months of which are taken up with pre-medical studies. Graduates receive a diploma which entitles them to practise medicine and surgery in any of the territories sending students. The diploma is not recognized for practice outside these territories, and is designed especially for their needs. One declared principle of the school is to preserve the native character of its graduates in order that they may more readily be accepted in the native social system, and thus spread their acquired knowledge. There is a students' hostel and accommodation for forty undergraduates, with sports amenities and a students' council. All students live in the hostel. Postgraduate courses are also held at the school.

The Governor of Fiji and High Commissioner of the Western Pacific, Sir Harry Luke, has said of the school: "It is one of the most beneficent gifts which British rule has conferred on the native races of the Pacific." Graduation ceremonies—the proudest occasion in the life of successful students—are held in the Legislative Council Chamber at Suva, and diplomas are presented by the Governor.

THE GENERAL PRACTITIONER AND SCIENTIFIC THOUGHT

The general practitioner is often praised, disparaged scarcely less often, and occasionally understood. A careful and sympathetic analysis of his difficulties was given in a paper read last week before the Royal Society of Arts by Dr. O. R. TISDALL. But the lecturer appeared to foresee the coming of State medicine in which the private general practitioner would disappear and doctors become servants of the State, responsible to it instead of to their patients. His disappearance, he said, would be a loss to the community, not because he is necessarily more efficient or capable than the State official who would replace him, but because of his irreplaceable position as confidant and friend of his patient. On the other hand, with the coming of State medicine Dr. Tisdall thought that the more scientific treatment of the patient was likely, it would be easier to have laboratory tests done at nominal cost, easier to refer the patient for examination, and easier for the doctor to keep abreast of new work by attending refresher courses. While the period of transition from private to public practice would be difficult, it had been already prepared for by the invasive activities of public services and clinics.

New Experiences and New Remedies

Dr. Tisdall pictured the newly fledged practitioner, starting with high hopes, full of painfully acquired knowledge, "and usually with a good conceit of himself," and finding in contact with the actual experience of practice many of his preconceived ideas swept away and his work subjected to limitations outside his control. He was wise if, notwithstanding a certain disillusionment, he still felt he could perform useful service to the community without seeking refuge in specialized or institutional work. The problem would be to keep himself up to date in a science and art in which new facts and an even greater number of new theories were constantly being thrust forward. The practitioner could, of course, study the medical journals, attend meetings of professional societies, and enter for intensive postgraduate courses. Most men who took their profession seriously did their best to familiarize themselves with scientific advances. But what constituted a real advance? Dr. Tisdall mentioned three major advances within his own experience of practice: the discoveries of insulin, liver therapy, and the sulphonamide group of drugs. The last-named discovery in particular brought up one aspect of the problem which constantly faced the practitioner—namely, the publicity given to medical innovations in the lay press. The patient saw the announcement of some sensational "cure" in a case which he thought similar to his own, and demanded that it be tried on himself. The practitioner could not try every new remedy, but he dare not neglect them all, and in respect of those he did try he came up against the constant dilemma of clinical treatment—*Post hoc, ergo propter hoc?* If a practitioner treats a case with an injection strongly recommended by authority and the patient is well next day, is it due to the injection or to the recuperative power of the patient? Nature is not always the most conformable of colleagues, and often she pushes in and effects a cure on her own with scant regard for the doctor struggling in her wake.

The Critical Faculty

It is not always realized that the general practitioner is very differently circumstanced from the hospital clinician, who can try out a new remedy extensively and have controls. How dare the general practitioner in the little community of his practice have controls! If one patient makes a spectacular recovery after treatment with a new drug another will want to know why it was denied him; and if, on the other hand, the drug is unsuccessful the patient will protest against being the subject of experiment. The solution can only lie, Dr. Tisdall said, in preserving a sense of proportion. The practitioner should be prepared to give a reasonable trial to any new development which has been accredited by those in whom he has confidence, but still he should preserve his critical faculty and decide for himself whether his patient has benefited or is likely to benefit.

In spite of the handicaps of general practice, the practitioner should not belittle his opportunities of developing his scientific knowledge. After all, he has unusual opportunities for making observations, and, while he can enlist the aid of laboratory tests, it is still for him to draw his own conclusions. Dr. Tisdall thought there was a regrettable tendency to regard the laboratory as the final court of appeal. Students seemed to think it was better to examine the patient's chest by *x* rays than to examine it clinically. Everyone admits that the accurate reports now possible from the laboratory and the *x*-ray room are of great value in diagnosis, and without them much limitation would be placed upon clinical work; but it is mere juggling with words to say that the one is scientific medicine and the other is plain medicine. It is for the clinician to weigh the evidence of the laboratory, balance it with the evidence of his own senses, and deliver the verdict.

Growing Edge and Individual Touch

Lord DAWSON OF PENN, who presided at Dr. Tisdall's lecture, spoke of the "growing edge" of the knowledge of medicine. In any branch of knowledge with a growing edge differences of opinion must be expected among those who followed and applied it (Dr. Tisdall had mentioned the dissension, sometimes slightly acrimonious, in the correspondence columns of the medical journals). But there was no profession in which there was less difference of opinion as to the basic facts. In the application of new knowledge, said Lord Dawson, the practitioner should have an open, progressive mind, but not a mind immediately influenced by the opinions of the market place. While medicine comprehended an increasing number of sciences and the range of knowledge which it demanded seemed ever to extend, the make-up of the individual patient remained much the same. In days gone by when violent epidemics laid whole communities low, mankind seemed to be reduced to a common denominator and the individual to be more or less effaced. This was so in the days of the great plagues and, to quote a modern instance, in some measure in the influenza epidemic at the end of the last war. But, in the main, infectious diseases were becoming less severe, and the less severe the disease the more did the individuality of the patient count. Lord Dawson believed that individual illness, and with it the art of treatment, would necessarily become more complex, requiring more training of the doctor in the interpretation of the patient. It was here that the value of the general practitioner came in, with his insight into the mind and feeling and circumstance of the people whom he attended. A State service would reduce the relationship to an official one in which the individual touch, the understanding sympathy, which was one of the great features of the best type of medical practice, would be lessened. But while individualism should be preserved there was need, Lord Dawson insisted, for more planning in objective observation and investigation. The real problem as he saw it was the combination of those two things: the ordered investigation of illness, probably in buildings set apart for the purpose, and individuality in the human contact.

DIAGNOSIS AND TREATMENT OF GAS CASUALTIES

The following memorandum on the diagnosis and treatment of gas casualties has been prepared for the Ministry of Health for the information of medical practitioners.

Of the poison gases likely to be used by the enemy there are two main types: (1) the vesicants (mustard group) and (2) the pulmonary irritants (phosgene group). A knowledge of the main clinical features of gas poisoning and of the essentials of treatment should be possessed by every medical man and woman in the country.*

I. Vesicants

Of these mustard gas is considered the most important. It accounted for upwards of 70% of all our gas casualties in the last war. It can be employed in shells and bombs and sprayed from aeroplanes. Its dangers should not, however, be overemphasized. Its mortality in the British Army in the last war was little more than 2%, and 80% of cases were fit for active duty within a month. *To secure such low figures a high degree of gas-mask and other discipline is clearly necessary.*

The early symptoms (which develop in the course of a few hours) include skin burns varying from a slight erythema to severe blistering and affecting the softer skin and moist surfaces especially; blepharitis and conjunctivitis; laryngitis, tracheitis, and bronchitis; vomiting. The sequelae in the graver cases include corneal ulceration, bronchopneumonia, and bronchiectasis.

The lesions may be caused by vapour or by actual droplets. The latter should be immediately removed from exposed skin by dabbing (not wiping) with handkerchief or linen, which should at once be discarded. When possible bleach ointment or paste or Anti-gas Ointment No. 2 should then be applied to the skin. The next indication is the earliest possible removal of contaminated clothes and footwear and free washing with soap and water. Treatment of the eyes, if affected, should always be given preference over treatment of the skin. It should include immediate and free irrigation with water. To prevent secondary conjunctival infection the instillation of albucid in a 2.5% solution four times daily is recommended. Later atropine 1% in ointment or in drops may be used to counteract the pain of ciliary spasm. Liquid paraffin drops to prevent sticking of the lids may be employed after twelve hours. Cocaine preparations and bandaging of the eyes must on no account be allowed. Eye-shades may be used in the early stages. Blisters should be aspirated with a hypodermic needle and syringe. For open skin lesions, after the stage of profuse exudation, the recognized surgical treatments for ordinary burns should be employed. Laryngitis and tracheitis should be treated with steam inhalations. Bronchitis and bronchopneumonia should be treated on general principles; it is possible that sulphapyridine may prove valuable in preventing the latter.

In the last war there was a high incidence of functional sequelae, including photophobia and blepharospasm, aphonia, and vomiting. Early reassurance as to the unlikelihood of blindness, discountenancing a too prolonged use of eye-shades, etc., may play an important part in treatment. *Once the early essential treatment has been given mustard gas casualties may be safely evacuated to a distance as stretcher or sitting cases according to their severity.* In the case of patients severely injured as well as contaminated with gas, elaborate washing, etc., will clearly be out of the question, but the clothes should be cut off as quickly as possible and local eye and skin contamination dealt with as effectively as the condition of the patient may allow. The order of urgency in such cases is: (i) removal of outer garments and shoes; (ii) methods directed towards saving life and treating shock; (iii) saving the eyes; (iv) cleansing the skin.

Another vesicant gas is lewisite. It is also a lung irritant, a nose irritant, and a tear gas. It is the more readily recognized on account of its early effects on the upper respiratory tract. When present in large quantity on the skin it can be absorbed and cause severe general and visceral symptoms of arsenical poisoning. For removal from the skin hydrogen peroxide (20 vols.) or a 20% solution of hyperol (urea peroxide) is a most effective counter-agent. If blisters occur they should be opened and the raw surface irrigated to lessen the likelihood of absorption. Otherwise the treatment is as for mustard gas.

II. Lung Irritants

Of these phosgene is the most important. It can be employed in shells or bombs. When the gas is present in very high concentration early death from asphyxia may occur in the case of inadequately protected persons. With the more usual concentrations immediate symptoms may be slight or absent, but dangerous symptoms may follow up to several hours after exposure. The likelihood of such symptoms developing is much increased if the exposed subject remains physically active. Every person, therefore, who has been exposed to phosgene vapour without gas-mask protection should become a stretcher case as soon as possible.

On arriving in hospital or at a treatment centre cases should be grouped into mild, moderate, and severe categories and, if possible, treated separately. The "mild" cases show a reddish flush on the face, increased respiration rate, and pain in the chest aggravated by coughing. Absolute rest, fresh air, fluids, and nursing are the chief indications, together with careful watching lest any of them pass into one of the graver groups. The "moderate" cases show greater respiratory distress, with varying degrees of pulmonary oedema, "blue" cyanosis, distended neck veins, a full strong pulse without great increase in rate. The indications are continuous oxygen by nasal catheter or B.L.B. mask (or in the less severe cases intermittent pure oxygen from a nitrous oxide bag), venesection, and nursing care.

The "severe" cases show collapse, coldness, a weak rapid pulse, and pallor with leaden "grey" cyanosis and no distension of the neck veins. There is profuse pulmonary oedema, often with froth pouring from the mouth and nose, and great respiratory distress with shallow and largely diaphragmatic breathing and the chest in the inspiratory position. The indications are continuous oxygen in high concentration with the B.L.B. mask or double nasal catheter, the flowmeter delivering at a sufficient rate to maintain a pink colour in cheeks and lips. Venesection should not be attempted. It may be necessary to lower the head and raise the feet to allow the oedema fluid to escape more freely. Morphine is contra-indicated. Atropine and adrenaline are not indicated. Although there are haemoconcentration and increased viscidity of the blood the use of all forms of intravenous fluid is at present considered inadvisable owing to the risk of increasing the pulmonary oedema. Warmth and the most attentive nursing are essential. Patients may be restored to health after as much as seventy-two hours of continuous oxygen administration. Pneumonia is an occasional complication. Late sequelae are rare. *It cannot be too much emphasized that oxygen properly administered is a life-saving therapeutic agent both in the "blue" and "grey" cases. Evacuation of phosgene cases to a distance until they have been pronounced out of danger should be prohibited. Even the slightest cases should be under observation and at rest for forty-eight hours.*

III. Carbon Monoxide

Poisoning by CO may result from leakage from gas mains after air raids or from the explosion of bombs in a confined space. Rest, restorative treatment, artificial respiration, and oxygen with carbon dioxide are the chief indications.

IV. Tear Gases and Nose Irritants

These do not produce casualties requiring hospital treatment. The main symptoms are lacrimation, sneezing, intense frontal headache, burning mouth and throat, nausea, and tightness in the chest. In a gas-free atmosphere the symptoms usually pass off in an hour.

Important Notice

The gas-mask, if properly adjusted and in time, gives full protection to the lungs and eyes against all these gases. In the event of gas attack the medical profession would have a most important part to play, not only in the recognition and

*A reprint of the 1940 edition of the War Office Medical Manual of Chemical Warfare (published by H.M. Stationery Office, price 2s. 6d.) is now in preparation. This 1941 edition will embody amendments covering recent recommendations for treatment.

the treatment of cases and the recording of any new phenomena, but also in the prevention of panic by constant reassurance, by insistence on gas-mask discipline, and by stressing the effectiveness of the protective and therapeutic measures at our disposal.

BRITISH PHARMACOPOEIA: NOMENCLATURE

The General Medical Council has approved names for certain substances which are now being produced, or are likely shortly to be produced, by British manufacturers, in some instances under licences granted by the Comptroller-General of Patents, Designs, and Trade Marks. These substances have hitherto been known under other names, which are given below together with the names now approved. The question of including these substances in the *British Pharmacopoeia* is under consideration, and if any of them is included the intention is that the approved name given below will be its official title.

Approved Name	Other Names
Diodone	Perabrodil
Diphenan	Butolan
Dithranol	*Cignolin*
Hexazole	Triazole (Azoman)
Mesulphen	Mitigal
Pholedrine	Veritol

The British Pharmacopoeia Commission hopes that the early publication of these approved names may lead to their general adoption.

Reports of Societies

CHEMOTHERAPY, SEROTHERAPY, AND HAEMOTHERAPY IN OTO-LARYNGOLOGY

At a combined meeting of the Sections of Otology and Laryngology of the Royal Society of Medicine on May 2, Mr. LIONEL COLLEDGE presiding, the subject of discussion was chemotherapy, serotherapy, and haemotherapy in diseases of the ear, nose, and throat.

Uses of Sulphonamides

Colonel L. E. H. WHITBY said that the principles for the use of sulphonamide drugs in this field were the same as in any other region of the body—namely, the infecting organism must be sensitive, the concentration of drug must reach an effective level and be maintained there, and the position in which action was required must be favourable. In acute otitis media statistical results and individual studies showed that the incidence of grave complications was reduced by chemotherapy, though factors other than chemotherapy, such as the prevalence of epidemic influenza, also affected the incidence of complications. Each case called for individual consideration as to whether surgery or chemotherapy, or both, should be employed. Pus always required drainage; bony involvement responded badly to chemotherapy. General well-being was a better guide to progress than the temperature chart. Sulphonamide drugs must be given boldly and in full dose. Inadequate dosage masked symptoms and failed to eradicate infection. Chronic aural suppuration responded less well, probably because of bony involvement. Nevertheless, secondary infection with *B. proteus* or *B. coli* could sometimes be controlled. The treatment of nasal sinusitis was generally disappointing unless begun in the stage of hyperaemia before pus formation was definite or bone was involved. Streptococcal tonsillitis and adenitis responded well, though statistical assessment was difficult. Complications in scarlet fever appeared to be reduced by a combination of chemotherapy and serotherapy.

Indications for Haemotherapy

Dr. H. F. BREWER said that the success of chemotherapy had greatly diminished the use of specific therapeutic sera. But chemotherapeutic action was directed against bacteria, and none of the new compounds affected toxins directly. In the field under discussion specific antitoxic serum was still the primary and essential treatment for active infection with the diphtheria bacillus (unresponsive to present chemotherapeutic agents), and as an adjuvant to chemotherapy specific serotherapy might be beneficial in acute infections (especially with complications and metastatic spread) by the pneumococcus, staphylococcus, and *Str. pyogenes*. The indications for haemotherapy were relatively infrequent and non-specific. As a pre- or post-operative measure to combat simple anaemia, stored blood up to fifteen days old compared favourably with fresh blood, and the reaction incidence was not significantly increased. Concentrated red cells afforded a means of raising haemoglobin percentage without unduly influencing blood volume. For anaemia associated with or dependent on sepsis or for a blood disease—for example, haemophilia or thrombocytopenia—fresh blood was to be preferred.

Chemotherapy and Ultra-short-wave Radiation

Mr. J. ANGELL JAMES said that in 1935 he began to use ultra-short-wave radiation in acute otitis media and acute sinusitis. During the period 1938 to 1940 both sulphonamides and ultra-short-wave radiation were used together whenever possible, and he had not attempted to assess accurately the relative influence of the two in the final result. In a series of 750 cases of acute suppurative otitis media seen during the three years before and three years after the introduction of the sulphonamides and ultra-short-wave radiation, of the cases which received early treatment 9% required a mastoid operation in the pre-sulphonamide group and 1.7 in the post-sulphonamide group. The corresponding figures for a group of 210 cases of acute sinusitis were 25% requiring operation in the earlier group and 7% in the group following the introduction of sulphonamides.

Mr. NORMAN JORY said that bleeding was so readily controlled that blood transfusions in otology were almost never required. Before the introduction of sulphonamides serum therapy appeared to offer the best help in the very ill case. It was natural to turn to an appropriate antiserum for help, and in some cases this appeared to give good and even dramatic results. The difficulty was to provide the specific antiserum, and the administration was not entirely without discomfort and risk. There was a growing tendency to begin treatment with sulphonamides earlier in the course of an infection. He drew attention to some of the untoward effects following their use. The evolution of less toxic compounds was likely in the future; meanwhile, he felt it undesirable to use sulphonamides in every case. They should rather be held in reserve to be used as necessity dictated.

General Discussion

Mr. T. B. LAYTON said that in thrombosed sinuses sulphonamides were likely to cause difficulty in diagnosis by masking the symptoms without touching the disease. If there was no organism in the clot, the clot was a physiological reaction and best left alone; if there was an organism there would be no symptoms arising from it until the breaking down of the clot allowed organisms to pass into the blood stream. If chemotherapeutic drugs were given in that type of case they would mask the only symptom which enabled one to decide on operation.

Mr. F. W. WATKYN-THOMAS also said that with chemotherapy there was a danger of masking the symptoms, especially in septic lateral sinus phlebitis. The sulphonamides might be administered in the very earliest stages of acute otitis media, but once it had become necessary to carry out a paracentesis the administration should stop, because if there was going to be any further spread it would be in the bone and in the very position in which sulphonamides could not reach it. The same thing applied even more strongly in any question of intracranial complication.

Mr. TERENCE CAWTHORNE said that he had looked up the recent literature and found records of 194 cases of septic meningitis which had recovered presumably as a result of chemotherapy. Since the introduction of chemotherapy he himself had had nine recoveries out of fifteen cases. In osteomyelitis of the frontal bone following frontal sinus infection he had treated three cases, not doing any extensive operation

at all, and all had recovered with simple drainage of the abscess. In two of the cases he removed some tiny flakes of bone three or four months later. Before chemotherapy extensive operations would have been done, in his experience disappointing and mutilating.

Mr. F. C. W. CAPPS referred to the dangers of chemotherapy when used without adequate clinical observation. He had tried to impress on practitioners that the subsidence of symptoms was not sufficient, and that until the drum-head was seen to return to its clinical normal the case must not be regarded as cured. If the drum was still bulging and reddened, even though symptoms had subsided, there was need for resort to paracentesis.

Mr. R. G. MACBETH asked if the sulphonamides were of any prophylactic use in tonsil excision and laryngeal operations.

Colonel WHITBY, on this last question, considered that a reasonable prophylactic course occupying two or three days was justifiable. The risk was very small, and the course could always be expanded to full treatment if required. If he had any reason to anticipate septicaemia he would employ these drugs prophylactically. As to the danger of prolonged courses of minimal doses, there were certain people who were sensitive to these drugs and unable to tolerate more than a gramme or two without exhibiting skin rashes or granulocytopenia or even agranulocytosis. Ordinarily the course was of seven to ten days and the total amount between 50 and 60 grammes. Intolerance was a question not so much of the amount as of the time. People became sensitized when even minimal amounts were given for prolonged periods. With a course of 50 grammes occuying ten days there was less likely to be trouble than with the same total amount spread over a month. As to antibody production in patients treated with chemotherapeutic drugs, there appeared from experiments on mice to be a certain, though not very durable, resistance to pneumococcal infection but not to streptococcal. There was something to be said for active immunization with vaccines, though against the streptococcus this was extremely transient.

The annual meeting of the Cardiac Society of Great Britain and Ireland was held at Oxford on April 18 under the chairmanship of Dr. A. G. Gibson. Dr. J. B. Herrick (Chicago) and Dr. Frank N. Wilson (Ann Arbor) were elected honorary members, in addition to Dr. Paul White (Boston), elected in 1938. Accommodation was kindly provided at Merton College, where books and records of William Harvey were on view. At the morning session there was a debate on the early signs of cardiovascular disease. In the afternoon the treatment of coronary thrombosis was discussed. Original communications, as arranged by the honorary secretary, Dr. Maurice Campbell, included papers on the right pectoral electrocardiogram in auricular fibrillation, the collateral circulation in coarctation of the aorta, the haemic factor in angina pectoris, the electrocardiogram of the Stokes-Adams attack, and a criticism of the term "chronic myocarditis."

The Ministry of Food announces that while the sale of milk to consumers is reduced to six-sevenths of the quantity sold during the first week in March, members of the National Milk Scheme, children receiving milk in schools, and inmates of hospitals, maternity homes, and nursing homes will continue to receive their full requirements. In addition, on the advice of the Special Diets Committee of the Medical Research Council, persons suffering from active tuberculosis, silicosis, affections of the mouth, throat, or gullet which prevent swallowing, gastric, duodenal, or anastomotic ulcer, illnesses characterized by high fever, and post-operative conditions may obtain a daily supply of milk up to a maximum of two pints on production of a medical certificate. This certificate is to be given on a form obtainable from the local Food Offices of the Ministry, which will ordinarily be supplied only on the request of a medical man. Criticisms of the procedure have appeared in our *Supplement*, and the British Medical Association is making representations to the Ministry of Food.

INDIA

Health of the Army in India

The annual report for 1939 on the health of the Army in India gives a satisfactory account of the British and Indian troops during the year which saw the outbreak of war in Europe. There were no serious epidemics, although civilian areas amidst which troops were placed suffered extensively from cholera, plague, small-pox, dysentery, malaria, and enteric fevers. Among British troops the hospital admission rate of 666 per 1,000 of strength during the year seems very large, and, indeed, it was an increase on the rate for the year before, but the death rate of 2.75 per 1,000 and the invaliding rate of 9.14 per 1,000 were lower, and all these rates during the last quinquennial period continue to show the fall which has been progressive since the last war. Among the Indian troops, though the death rate was down, the hospital admission and the invaliding rates were up, but it is stated that the increases can be fully accounted for by the conditions of war service, and the return or influx of large numbers of men potentially infected with malaria and other prevalent diseases. Malaria and dysentery—the percentage figures are exactly equal—share the top place in the list of principal causes of sickness among officers of the British Army in India, and these are followed by catarrhal jaundice and cellulitis. Among the soldiers malaria has first place, followed by cellulitis, and—a good way down—tonsillitis, but dysentery comes sixth, and is only half as frequent as a cause of admission as malaria. Malaria, sandfly fever, and dengue between them are responsible for just over 90 per 1,000 admissions. Before the last war and for a year or two afterwards the malaria admission rates among British troops were considerably higher than among Indian, but during the last ten years the Indian rate has been very much higher than the British, and in 1939, while the admission rate for British troops was 58.1 per 1,000, for Indian troops it was 118.3. It is a different story with the dysentery-diarrhoea group. Before the last war the admission rates were higher among Indian than among British troops, but since 1919 they have been considerably lower, and in 1939 the admission rate for Indian troops was only half the figure for British, and the British figure was the highest for twenty years. Comments from commands and districts indicate that the prevalence of dysenteric infection is due to the lack of sanitation surrounding the troop areas. The seasonal incidence of these diseases appears to be different among the British and among the Indian troops: last year for the former the peak month was August and for the latter May. Respiratory diseases have been little in evidence, and there have been no epidemics other than minor outbreaks of mild influenza and pharyngitis. Nor is there any sign among the military populations of the steady increase in tuberculosis which appears to be occurring in the civilian population. Seventy pages of the report are occupied by contributions on the preventive and curative work carried out by the military medical services. A detailed account of the pathological work undertaken seems specially useful.

Public Health in Burma

The outstanding figure in the vital statistics given in the report for 1939 on the state of public health in Burma is the infant mortality rate (203.85 per 1,000 births), which is higher than in any of the Indian provinces except the Central Provinces, and three and a half times higher than in England and Wales. One explanation is that infant mortality in Burma is primarily due to malnutrition. Owing to Burmese customs and prejudices most mothers, even of the middle class who could afford a better diet, try to starve themselves during pregnancy, believing that if they live strictly on a rice diet with some dried fish they will escape the ailments from which people who take plenty of fresh and rich foods may be expected to suffer. The major epidemics in Burma are cholera, plague, and small-pox. A good deal of systematic anti-cholera work seems to be undertaken, including the purification of water supplies, control of the sale of food and drink, and

protection by means of inoculations, nearly a quarter of a million of which were performed during 1939. The most important measures against plague are those which deal with the administration of the bazaars, the storing of grain, and the enforcement of building by-laws. The number of deaths from small-pox (125) is the lowest ever recorded. The law of the country gives district councils and municipal committees power to frame rules for compulsory vaccination, and out of 105 of these local bodies ninety-three have done so. Malaria is one of the most widely prevalent diseases of the country, but its incidence cannot be exactly gauged because the registration of deaths is carried out by village headmen, who are apt to include all fatal cases of malaria as "fevers." Not only are malarious areas being reclaimed, but other measures are being undertaken, including the introduction of larvivorous fish into ponds and wells. Prof. Lyle Cummins recently visited Burma to study measures necessary to control tuberculosis. He found the incidence very low except in Rangoon. As a result of his report the Burma Tuberculosis and Leprosy Relief Association has offered Rs. 2½ lakhs (say, £18,000) to the Government towards a tuberculosis hospital in or near the capital.

ENGLAND AND WALES

London Hospital in Essex

The London Hospital, following the example of Guy's and St. Thomas's, has opened a country branch. During the last week of April an annex in Essex was taken over for the accommodation of, to begin with, 130 "London" patients, the number eventually to be 360. Sufficient staff and equipment have been provided to furnish in the country environment all the services of the mother hospital. There are four resident doctors at present, two registrars, and seventy-five nurses, but the number of nurses will eventually be increased to 180. A nurses' home is being built, and is expected to be completed in about ten weeks' time. The services of the consultants attached to "The London" will similarly be available for the Essex patients. The annex consists of twelve brick and steel huts, linked by canopied concrete paths which afford protection against the worst weather conditions. A modern operating theatre and other facilities have been put in, as well as adequate kitchens. Should the building in Whitechapel be rendered untenable by enemy action—it has already had bombs and incendiaries—the Essex institution will become the headquarters, but in the meantime the whole administration will be carried on from "The London," on the spot where the hospital has carried out its work for two hundred years. There are 350 beds in Whitechapel, and with the 360 to be presently available in Essex "The London" still claims to be England's largest voluntary hospital.

The Hospital Almoner in Wartime

The war has revolutionized the setting of the almoner's work and created a new demand for it. In a large voluntary hospital she may now find herself serving not a local district but a region. Patients from a London hospital may be distributed over a wide area of the Home Counties. One county council has appointed a travelling almoner to work in several hospitals under the E.M.S. scheme. The bombing of London and other cities has created a need for just such social service as the almoner can render. Her work has extended beyond voluntary hospitals to municipal and county; it also seems to be developing in connexion with the needs of old people evacuated to public assistance institutions. Hospitals which at the beginning of the war closed or restricted their almoners' departments have found it necessary to reinstate the almoner and extend her work. In 1939 there were fifty almoners out of work, now there are practically none. Last year seventy-five students received the certificate of the Institute of Hospital Almoners, and at the close of the year there were about 100 women in various stages towards qualification. During the first ten weeks of this year twenty-one new posts were notified, as against thirty-one during the entire year 1940. The impetus to the movement was given by the Minister of Health when at the end of last year he strongly recommended all hospital authorities in the E.M.S. to employ almoners, and intimated that part of the expense of establishing new almoners' departments might be met by Government grant. Although the work has extended from one department to another there are still one or two fields—notably venereal diseases clinics—where there is reluctance to develop almoner's work. The Countess of Limerick, speaking at the annual meeting of the institute the other day, said that the registration of women was creating some misgiving among those responsible for the training of almoners, and she felt that it was of the utmost importance that there should be a steady flow of well-educated girls for training for this important work. In view of the Ministry's encouragement to hospitals to employ almoners, it is very unlikely that suitable girls who seek this profession will be prevented from doing so by demands to do other national work.

Correspondence

Chemotherapy in Acute Otitis Media

SIR,—I have been deeply interested in two recent publications in the *Journal* on chemotherapy in acute otitis media, the first by Dr. J. B. Jessiman (March 15, p. 399) and the second by my old chief, Mr. Lionel Colledge (March 22, p. 455).

Dr. Jessiman records a series of cases of acute otitis media (all in children) which responded well to chemotherapy, though not without anxiety in some instances. I have felt reticent in expressing enthusiasm for this form of treatment, and the reason is perhaps not far to seek. I do not see so many cases of acute otitis media nowadays in their initial stages, as they are treated by my colleagues in general practice by chemotherapeutic means with marked success. But the ones I do see are those which for some reason or another have either failed to respond to the drug or are left "sitting on the fence." By this I mean that complete resolution has not occurred, yet the usual clinical picture of otitis media is scarcely recognizable. In these cases the residual affection seems to vary: in one it may be persistence of pain; in another, persistence of temperature (often without a corresponding rise of pulse rate). Where the drum has ruptured spontaneously or has been incised there may be persistence of discharge and deafness. The appearance of the patient is striking: he looks as "sick" as he feels; and following the usual clinical picture of toxic absorption he looks and feels worse when the discharge is scanty, but often with only a mild pyrexia or even none at all. Even our old friend the state of the tongue is a less reliable guide as to the need for surgical intervention.

The conduct of a case of acute otitis media after chemotherapy had apparently failed is not always as straightforward as might be expected, even though it might reasonably be assumed that half the battle had already been won. Two recent cases may be quoted.

A middle-aged man failed to respond satisfactorily to sulphapyridine after an attack of acute otitis media. A paracentesis was performed and the culture grew haemolytic streptococci. Discharge after paracentesis was scanty. There was little indication for intervention except persistent deafness and pain at night only, which was sufficient to keep him awake. I drained a mastoid full of pus, after which the whole condition cleared up rapidly.

The second case was in a man of about 30 years who was successfully treated with sulphapyridine for an attack of acute otitis media, and in spite of spontaneous rupture of the drum and discharge he had a dry ear in five days. After a week it flared up again, and when I saw him four days later he looked fairly well, but spoke like a man with a quinsy, due to a generalized oedema of his pharynx. His temperature was swinging up to 104° F., but his pulse was slow in comparison. He had a central perforation in the drum, through which was coming a copious flow of pus. He had no mastoid tenderness. His tongue was fairly clean but he felt shivery. At operation his mastoid was found to be full of pus, which welled up from the region of the tip

cells, and elsewhere there was a remarkable amount of sequestration of bone. The lateral sinus appeared normal. Culture of the pus grew haemolytic streptococci. He had a stormy post-operative period, as his temperature continued to swing up to about 101° F., and there developed a brawny swelling in his neck with extreme superficial tenderness. This swelling spread rather rapidly and sulphapyridine was reinstituted in fairly heavy doses, a check being kept on his blood picture. As he still felt shivery it was difficult to exclude a lateral sinus or jugular bulb thrombosis as a possible complication. Expectant treatment with dry heat and ichthyol dressings was sufficient to produce a free flow of pus, which welled up into the wound from below the mastoid tip. Concurrently with this his pharyngeal swelling subsided.

It is still a little difficult to be certain of the exact pathology of this sequence of events. Did the sulphapyridine control or obscure an actual sinus thrombosis? The state of the patient's neck did not encourage the application of Queckenstedt's test or invite surgical procedures on the jugular vein. Was the origin of the deep pus the result of a Bezold's type of mastoiditis, for though the bone was not very cellular the flow of pus from the ear before operation was profuse? There was little to support the diagnosis of apicitis, nor did x-ray examination of his mastoids furnish conclusive evidence.

Now I am not averse to giving due credit to chemotherapy for any beneficial effect it may have exerted in this case, and indeed it may have been largely responsible for safely piloting the patient and myself through dangerous waters, but nevertheless I had an uncomfortable feeling that the whole clinical picture was being obscured by a chemotherapeutic fog.

Mr. Colledge has made two very important points. The first is a warning that paracentesis should not be unreasonably withheld when the tablets alone have failed to abort or control the infection; and the second is the necessity for making a culture of the pus so that the optimum agent may be used.

It would seem that in the first instance treatment must be empirical as regards the selection and dosage of the drug employed, as confirmation of the infecting organism can only be obtained after discharge from the ear either starts spontaneously or follows paracentesis. Sometimes the appearance of the drum may suggest a streptococcal rather than a pneumococcal infection. But after chemotherapy has been instituted the appearance of the drum, together with indifferent physical signs, may even suggest the possibility of a *Streptococcus mucosus* infection.

I do not wish to decry or condemn for one moment the use of chemotherapy in acute otitis media, but rather to bring to the notice of those primarily concerned the possibility of failure (which some will scarcely admit) and the consequences of delaying orthodox surgical treatment. A throat swab, or better still a post-nasal swab, might give an early indication of the organism likely to be responsible for the middle-ear infection, and as a rough guide I suggest the following procedure should be adopted.

(1) Take a throat swab and if possible a post-nasal swab. (2) Institute chemotherapy (empirically). (3) If attack is not aborted or at any rate does not appear to be resolving in, say, seven to ten days (or earlier if necessary), the case should be referred to an aural surgeon, a paracentesis should be performed, and a culture be made from the pus. (4) In the light of this knowledge the optimum drug should be employed. The dosage may need alteration as well, for it must be remembered that, though adequate concentration must be maintained, overdosage may be not only dangerous but ineffective due to a state of saturation which appears to inhibit natural resistance as well as bacterial activity. In conjunction with this I have noticed that mastoid wounds seem particularly sluggish after chemotherapy. (5) If still unsatisfactory at the end of, say, a further ten days, the whole case must be reviewed and treatment of contributing factors such as nasopharyngeal infection (T's and A's in children) or mastoid involvement must be considered. A timely mastoidectomy may prevent the condition becoming chronic with consequent impairment of hearing.

Surgery should always be ready to enlist the aid of modern therapeutic measures, and such measures may even dispense with the need for the knife. But fundamental principles of surgery such as the drainage of pus and the removal of dead tissues can scarcely be discarded as yet in favour of any other means.—I am, etc.,

Canterbury, April 23. CHARLES OXLEY.

Obscure Nervous Effects of Air Raids

SIR,—It is curious that Mr. Tom Harrisson's letter (April 12, p. 573) and Dr. H. Crichton-Miller's comment upon it (April 26, p. 647) have not aroused more interest. I am sure that cases of mild stupor following severe bombing are much more common than appears. One can hardly agree with Dr. Crichton-Miller's statement that these cases are *formes frustes* of encephalitis lethargica or that a competent rhinologist could confirm the diagnosis. I feel that Dr. Crichton-Miller perhaps has made a slip of the pen, and really meant toxic encephalitis due to sinusitis, and not encephalitis due to epidemic virus infection. I would suggest that the stupors in these cases are caused by: (1) actual concussion due to the impact of blast (blast acts as a solid body, and it is easy to see how it ricochets down a road, breaking windows in patches on alternate sides of the rows of houses. Surely such impact could cause real concussion); (2) toxic encephalitis (? as suggested by Dr. Crichton-Miller) due to release of toxins, perhaps through a damaged cribriform plate or into the blood stream from sinuses, teeth, etc.; and (3) a reflex reaction without organic basis similar to the "death shamming" of animals and insects. It would be interesting to hear the opinion of an expert such as Dr. Pickworth on the toxic encephalitis theory.—I am, etc.,

London, W.1, May 3. CLIFFORD ALLEN.

Medical Man-power

SIR,—Could you, or someone more in touch than I am with the official point of view, answer the following question? Why, with so many highly qualified refugee doctors in our midst, is it necessary to send America an S O S for a thousand medical men to help us out of our difficulties? I can understand the objection to the admission of those of non-British birth into the fighting Services, but I gather that many of the recruits are required for our hospitals. If we have allowed these medical refugees to take British qualifications and to settle here, it seems illogical that we do not permit them to work for us when we are in need of their skill. I understand that a few of them have wielded pick and shovel in the Pioneer Corps. Surely this is a waste of highly qualified men.—I am, etc.,

London, W.1, May 5. KENNETH WALKER.

SIR,—Dr. Charles Franklyn in his very relevant letter (May 3, p. 690) includes the following query: "What has happened to the thousands of consultants and general practitioners from denuded areas whose practices have virtually disappeared?" From some recent experiences of my own I am moved to press that this question should be clearly answered. Owing to what we are informed is an "acute shortage of medical personnel" in Britain the services of many doctors from abroad are now being solicited and accepted. Is it perfectly certain that all our native practitioners whom the oncoming of this war has deprived of their clientele have been given full opportunity to place their experience and special aptitudes at the disposal of their country in her hour of need?—I am, etc.,

Helmsley, York, May 4. A. J. BROCK.

Overburdened Doctors in Reception Areas

SIR,—In view of the acute shortage of civilian doctors in rural areas it is surprising that an overburdened profession has done so little to enlist the much-needed, and apparently readily available, medical aid from America.

It is hardly necessary to enumerate the diverse factors which to-day make medical practice in a reception area an impossibly heavy and difficult task—a task which must be shouldered without assistance or respite and which grows more unmanageable with each fresh bombing raid on our cities, as more and more evacuees crowd into these already over-populated areas. When the exhausted doctor himself

succumbs to intercurrent infection there is panic: there is no locumtenent to take his place. Yet, as recently as last January, you published a letter by Halliday Sutherland intimating that out-of-work doctors were pining for jobs. I should be very grateful to hear from these, if they still exist. If not, would any colleagues who see their own case described in this letter communicate with me with a view to directing a joint appeal to such medical authorities in America as may be in a position to come to our aid? I have already sent such an appeal on my own initiative, and have suggested that the most effective form of aid would be the establishment of a pool or unit of American doctors in Britain, members of which would be on call to go as locumtenents or assistants to overburdened practices in the country.

If the threat of a major epidemic occurring at any time is to be catered for at all it must be done in advance; under present conditions few of us can contemplate such a threat without forebodings of disaster.—I am, etc.,

Bagshot, May 3. S. GRAHAM.

Distribution of Air-raid Casualties

SIR,—Complete co-ordination of the casualty services is of paramount importance. The Ministry of Health might issue definite instructions to be carried out. I suggest a few.

(1) The medical officer on duty at main control, whoever he is, shall be the only medical officer in the control room, and from him orders will be given to sub-control, hospitals, first-aid posts, and depots, as well as to his staff. (2) The group officer is not necessary on the main control; he should visit each hospital where casualties are being admitted. (3) There should be no necessity for medical superintendents to telephone to main control, except for a visiting team or for some special advice or requirement. Hospitals should have a rota of priority cases coming to them as outlined below; and Control, knowing the "bed state," could advise of coming cases. (4) Hospitals with four operating theatres should take precedence over those with lesser number and should be given the first thirty cases; those with two theatres the next twenty cases; and those with a single theatre the next ten cases. When these numbers have been distributed sufficient time will have elapsed for the same distribution to be gone through as many times as necessary. Thus there will be no delay in treatment nor any overworking of the surgical staff. There should be no misuse of medical man-power by putting such on "one-way traffic," which can be done by a nurse or orderly. (5) The Minister of Health should control hospitals, first-aid posts, depots, and first-aid parties, nurses, ambulances, and rescue parties. The worth of the rescue parties is mainly life-saving *during a raid*, and they should work in conjunction with the first-aid parties, who should be taught rescue work forthwith. Review should be made of the physique and competence of all depot personnel. (6) The incident officer is one of the police officers; I submit that a medical man should be the director for the competent direction of first-aid parties. (7) The importance of a mobile unit with its doctor cannot be over-emphasized, especially in classifying cases and deciding what is a serious case. Conditions of air-raid casualties mislead first-aid party men: if we get more casualties per bomb the value of the mobile unit will be better recognized. (8) Every doctor of main control, every clerk there, every M.O. of first-aid posts, every medical superintendent of a hospital, every depot superintendent, every sub-control, the head of the fire brigade, A.R.P. officers, and every ambulance driver should be given a copy of the instructions for the whole service. (9) As the M.O. at control knows the bed state and the distribution of the cases, there will be no switching of ambulances except to circumvent road blockages, about which both the incident officer and main control would have information, but drivers of ambulances should know all alternative routes. The responsibility for this rests on depot superintendents, who should test them from time to time. (10) The duty of calling outside help of any kind rests with the A.R.P. officer after the casualty medical officer has advised him of its needs. (11) Alternative "shadow schemes" for hospitals are already a duty of the M.O.H. and group officer. (12) Ambulances to remove cases from hospitals during a raid are not practicable or advisable.—I am, etc.,

April 28. CO-ORDINATION.

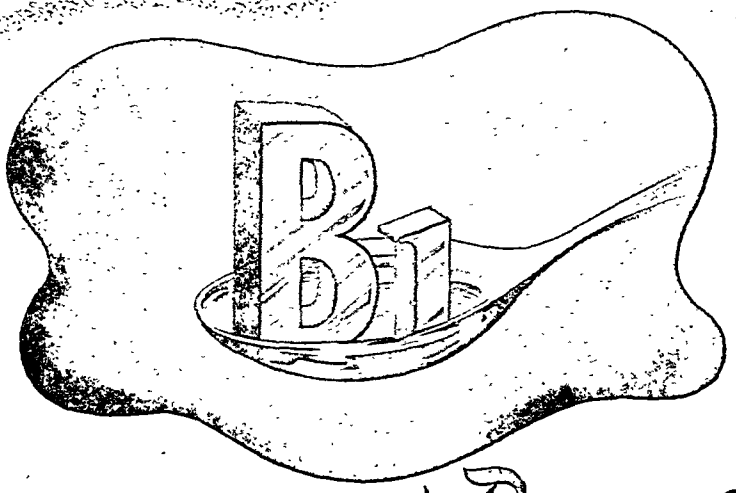
Mobile Units

SIR,—As some correspondents consider mobile units to be of little use I should like to make the following suggestions based on experience in one of our most heavily attacked towns. (1) Where a large number of casualties are reported a doctor and the unit are sent. (2) Where there are a few casualties in a *highly dangerous* place a doctor and a nurse are sent if serious cases are reported requiring a doctor. (3) The vast majority of incidents will consist of several houses bombed in one or more adjacent roads. If casualties are present *or suspected*: (*a*) in one house a doctor and a nurse are *always* sent if possible; (*b*) in several houses, a doctor and the unit are dispatched.

The routine in 3 (*b*) is that the doctor with a nurse and several auxiliaries rapidly visits all casualties in his own car, leaving a nurse at each house if required. He thus grasps the whole situation at once and acts as the occasion demands. Where buried persons are likely to be dug out soon nurses are left to call the doctor when required. It should be noted that the personnel are scattered in case of bombs falling. The van, which has followed after the doctor's car, is stationed near the centre of the incident.

The doctor should be able to go with a nurse to any place strictly local to his station whenever he has heard a bomb drop there and to call out his unit later if required. He will notify the Report Centre of his movements before leaving his station, and if he has to remain on the incident he is visiting he will send a report through a warden and warden's post to the Report Centre. Much valuable work is done in this way, especially as the doctor (and unit) is often there before any first-aid parties.

It is very important that doctors should carry bags stocked for emergencies and nurses should carry light packs on their backs containing dressings, etc. This enables the doctor to work (as he often must) at some distance from the van, prevents loss of time in fetching things, and minimizes risk to life in unnecessary walking about. The van should be adapted so that injections of A.T.S. can be given in it at night if necessary.



I completely disagree with the suggestion that a doctor should wait until someone (generally at first a member of a first-aid party) reports a case of severe haemorrhage or one requiring morphine, because usually the quickest way to obtain a doctor's help then is to rush the patient into hospital. Under the scheme outlined the doctor is on the scene before or soon after the first-aid party. If these suggestions are carried out there will be no doubt about the value of mobile units.—I am, etc.,

April 23. MAURICE E. J. PACKER.

Bureaucratic Surgery

SIR,—I suspect that there are many members of the E.M.S. who feel that Mr. Norman Lake voiced their feelings in his letter (April 19, p. 602). On the surface, it would seem almost insulting to suggest that scalp wounds cannot be dealt with satisfactorily by a general surgeon; or that he is so "dull" that he may overlook the possibility of injury to bone or brain. Incidentally, how many surgeons endeavour to ascertain the presence of injury to underlying brain if the skull is found to be intact? I wonder what comment Mr. Lake would make upon the following experiences of recent months, and what steps he would wish taken in an attempt to avoid repetition of such errors.

(1) *Case of 1-in. scalp wound:* stitched at F.A.P.; fracture with penetration of brain by bone fragments not detected until one week later; ultimately, death from septic encephalitis. (2) *Case of compound depressed fracture, with involvement of the brain:* inadequate operation by an (?) inexperienced surgeon in a general hospital, without even shaving the hair; *B. welchii* infection, ultimate recovery. (3) *Case of extensive compound depressed fracture, with involvement of the brain:* operation by a surgeon competent in general work; the hair not clipped for more than 1 in. from skin edges. (4) *Suture of an extensive irregular scalp laceration without excision:* inadequate shaving; wound infected and skin necrosis; C.S.F. leaked through infected wound from undetected small perforating fracture of the vault.

Increased Dosage

In view of the trend towards increased dosage of Vitamin B1 both here and in the U.S.A. it has been decided to raise the strength of 'Betaxan' tablets from 1 mg. to 3 mg. pure synthetic crystalline Vitamin B1 and the strength of the 2 mg. ampoules to 5 mg., and of the 10 mg. ('Forte') ampoules to 25 mg.

'Betaxan' tablets will now contain *three times* and 'Betaxan' ampoules *two-and-a-half times* the amount of Vitamin B1.

As no increase in price will be made, these greater strengths constitute a considerable reduction in price. The 1 mg. tablets are available at reduced prices.

PACKINGS:

'Betaxan' tablets 1 mg. and 3 mg.
Tube of 20, Bottles of 100 and 500

'Betaxan' ampoules 5 mg. and 25 mg.
Boxes of 3 x 1 cc.
" " 15 x 1 cc.
" " 50 x 1 cc.

So long as stocks last 5 mg. and 10 mg. ampoules will be available.

Now made in England

2153

These are the more serious cases; others less grave could be added to the list.

No one doubts the ability of Mr. Lake or indeed any other competent surgeon to excise a scalp wound; but since casualties are many and the patients can have no choice in selecting their surgeon, and since the judgment and ability of hospital staffs vary in degree, an effort must be made to avoid errors and omissions which so easily lead to a fatal issue. Scalp wounds can be trivial, but they can also conceal grave dangers; therefore they should always be regarded as potentially serious until proved otherwise.

The reason for transferring cases of nerve injury is surely very sound. Nerve suture itself is only one item in the conduct of the case. After-care is at least as important, and requires prolonged treatment, for which the best facilities are to be found at orthopaedic centres, where there is the further advantage that the surgeon who operates can watch the result of his handiwork.

The present methods of solving these problems will undoubtedly cause heartburning and perhaps resentment in the surgeon who wishes to tackle everything. As always, the acid test is, What is best for the patient?—I am, etc.,

D. W. C. NORTHFIELD, M.S., F.R.C.S.,
April 28. Surgeon in Charge of a Special Head Centre.

Orthopaedics and Orthopaedic Surgery

SIR,—The annotation on "Physical Medicine, Orthopaedics, and the Services" (April 26, p. 633) calls for comment. Instead of dealing with orthopaedics, the article follows a train of reasoning based upon references to orthopaedic surgery. Is this not a case of *petitio principii*? It begs the question. Orthopaedics and orthopaedic surgery are not one and the same thing. Orthopaedic surgery is only a part, and actually not a major part, of orthopaedics. The origin, development, and growth of orthopaedics have rested mainly upon matters relating to physical education, the problems which confront medicine as distinct from surgery, and upon the treatment of disabilities due to trauma. Orthopaedics has no real balanced future considered merely as orthopaedic surgery alone. The article differentiates so seriously against orthopaedics in favour of physical medicine that it amounts to special pleading. Considered on the basis of the actual title of the article, its recommendations cannot, in my opinion, be sustained.—I am, etc.,

Edinburgh, May 3. W. A. COCHRANE.

Agglutinin Titres of Pooled Sera

SIR,—Your correspondent Dr. J. T. Rice Edwards (April 26, p. 644), commenting upon the case reported by Drs. R. Mayon-White and O. M. Solandt from this depot, hazarded the opinion that iso-agglutinins may be present in appreciable quantities in pools of sera prepared from the bloods of Group A, B, and AB donors. In the preparation of such serum pools at the S.W. London Blood Supply Depot the serum is pipetted off from each individual bottle, together with a small number of red cells in suspension. When these sera are mixed the agglutinogens of these red cells help to neutralize the corresponding iso-agglutinins of the pooled sera. The methods employed at the other depots, from which pools of serum are obtained for the Medical Research Council's Serum Drying Unit which supplied the dried serum used in the treatment of this case, also involve a slight contamination of the serum with red cells.

Moreover, the sera themselves contain in solution group-specific substances (Schiff, *Klin. Wsch.*, 1924, **3**, 679). This observation has been confirmed in this depot by Dr. E. F. Aubert. In a paper shortly to be published he shows that the mixture of sera, Seitz-filtered to remove red cells and red cell debris, of Group A and B donors results in a diminution of the respective beta and alpha iso-agglutinins to titres which would be of no significance in transfusion work.

Pools of serum produced in this depot have been shown to have agglutinin titres so low that no naked-eye agglutination with A and B red cells can be detected. Plasma pools have similarly low agglutinin content.—I am, etc.,

J. F. LOUTIT,
April 28. Medical Officer in Charge, S.W. London Blood Supply Depot.

Injury and Internal Disease

SIR,—The paper by Dr. G. F. Walker (May 3, p. 659) will, I trust, attract wide attention. I for one should like to express to the author my admiration for its clarity and precision.

Personal experience in clinical, medico-legal, and literary work on two of the subheadings—cancer and diseases of bones and joints—suggests that two small additions might be welcome. The first concerns the author's Table III, in which he gives four generalizations as to the shortcomings and conflicting views in the literature. Here I should like to add one which to me always seemed most impressive. It is the bewildering variety of meanings read into the term "trauma." The author rightly uses it only occasionally. "Injury" is much better and less apt to be twisted to fit into strange theories. By a curious coincidence a classical example of what can be done with the words "trauma" and "traumatic" is provided in the same issue in the letter by Dr. C. Leleu on the cause of appendicitis (p. 689). Do we really agree that its cause is a "trauma"? I doubt it. But the point is that what later in this letter is described as "trauma to the blood vessels" is no trauma at all. The word "trauma" means nothing but injury. It is its translation into Greek. Once we begin using it as an equivalent for all kinds of pathological changes—congestion, irritation, physiological strain, the so-called mechanico-functional trauma to bones and joints of German writers—it assumes so many ill-defined meanings that it is in danger of losing its only true and well-defined one—that of injury or accident.

The second addition refers to the much-discussed problem of the part injury is said to play in the causation of sarcoma—more especially bone sarcoma, giant-cell tumours, and bone cysts. In a paper on "Osteitis Deformans Paget and Osteitis Fibrosa v. Recklinghausen" (*Ergeb. Chir. Orthop.*, 1933, **26**, 381) I tried to show that neither should ever be regarded as being commonly due to injury. Behring (*Acta chir. scand.*, 1930, **66**, 197) found in his large series of patients with sarcoma of the long bones that only 31% mentioned injury in their history; of those with giant-cell tumour of the long bones 33%. The mere possibility of a connexion he admitted in 17.5 and 18% respectively. As to bone cysts and "brown tumours," only six out of 165 cases reported between 1925 and 1932 by different authors seemed to me to admit injury as a possible cause, while their authors thought of it in 20. In twenty-four of my own cases of bone cysts and "brown tumours," four patients only mentioned injury spontaneously; all were asked, and the majority expressly denied that any injury had been suffered.

It is well to remember that, although cysts and benign and malignant tumours are not very rare in the jaws, none was then (1932) known to have followed fractures or the innumerable lesser injuries involved in boxing. Nor did I find a single case where a tumour had been ascribed to such cause as the severe jolts, kicks, infractions, or fractures at either football or ski-jumping. These statements apply, of course, only to point (*a*) in Table I of Dr. Walker's paper—that is, to injury as the only cause of the disease in any given case.—I am, etc.,

London, W.1, May 3. L. S. MICHAËLIS.

Subcutaneous Ligature of Varicose Veins

SIR,—I have read with interest the article (April 26, p. 626) by Dr. H. S. Russell describing subcutaneous ligature of varicose veins. I feel that it would be a pity if this method became widespread without a little further thought. It is clear that his operation cannot be performed at or near the saphenous opening, from the risk of damaging more important structures. It was the haphazard ligature of the saphenous vein somewhere in its course that brought the so-called Trendelenburg operation into disrepute. It was soon found that unless the saphenous was ligatured at its entry into the femoral vein, *and all its tributaries also ligatured*, recurrence would take place from anastomoses above and below the ligature.

The proper ligature operation demands a complete exposure of the vein at its highest point. This can be and is usually done as an out-patient procedure under local anaesthesia, and it is an important part of the treatment that the patient should not be put to bed. It therefore incommodes the patient no

more than Dr. Russell's blind method, which must be at the best uncertain. But the operation is not to be considered easy, and demands all that care and attention associated with surgical procedures and perfect theatre technique, otherwise tragedies will occur. It is not an advance to operate in a consulting room, nor is it ever wise to carry out any treatment, much less one associated with needle pricks, with the patient standing up.—I am, etc.,

NILS L. ECKHOFF, F.R.C.S.

Guy's Hospital, S.E.1, April 28.

SIR,—Dr. H. S. Russell (April 26, p. 626) is to be congratulated on his method of temporary subcutaneous ligature of varicose veins with silkworm gut inserted by means of a perineal needle. Where the vein is not too obscured by subcutaneous fat the suture can be inserted even more simply by passing a hypodermic needle under the vein and threading the suture through it. As the puncture is similar to what will be used in injecting the veins no local analgesic seems called for.—I am, etc.,

Birmingham, May 3. J. W. RIDDOCH.

Natural Therapeutic Agents

SIR,—May I offer a practitioner's applause to Captain Leslie Saunders on his admirable article (April 26, p. 624) on derris root and scabies, in which he describes the efficacy of the natural derris root in the treatment of scabies. It has occurred to me that pharmacological research, while concentrating on pure chemotherapy, has left untapped many natural therapeutic agencies. For instance, the virtues of rhubarb root, a favourite and valuable remedy with all practitioners, have not been completely surveyed. Is there not some pharmacological relationship between the anthraquinones of rhubarb and its allies and the naphthaquinones of vitamin K? They both appear to improve the body by liver action. Or again, would rhubarb be of more value in psoriasis than its constituent chrysarobin? One hesitates to reintroduce the idea of pleomorphism into pharmacology, but I think it is worth consideration, "lest we miss the many-splendour'd thing."—I am, etc.,

Kearsley, Lancs, April 28. D. OCKMAN.

Adrenal Grafts in Addison's Disease

SIR,—Dr. J. J. Conybeare (May 3, p. 688) doubts whether Drs. Katz and Mainzer's case of successful grafting of an adrenal gland had Addison's disease because there was no pigmentation.

That adrenal grafting can be effective in cases of Addison's disease seems substantiated by the fact that in a deeply pigmented, bedridden patient with an extremely low blood pressure I grafted an adrenal in May, 1935. The patient was shown at the Royal Society of Medicine by Dr. Keele in November, 1935, and again in September, 1939. I saw her quite recently; she stated that she was quite well and was working as an Army cook. She was still deeply pigmented.—I am, etc.,

London, W.1, May 2. HAMILTON BAILEY.

Renal Complications of Sulphapyridine

SIR,—Attention has been drawn recently to the dearth of literature in this country on the renal complications of sulphapyridine (Major F. R. Fletcher, February 15, p. 242; Mr. J. C. Leedham-Green, April 19, p. 586). I think it may be of interest to mention a case of haematuria and anuria following sulphapyridine therapy.

The patient, a man aged 46, was admitted to hospital with lobar pneumonia. On January 28 sulphapyridine was given in the usual dosage, and on February 1 haematuria, with pain in both loins and tenderness, was noted. This was followed by complete suppression of urine. The drug was stopped, a total dosage of 26 grammes having been given. On February 2, 40 c.cm. of a 50% solution of glucose was given intravenously and hot packs applied to the loins; the anuria, however, persisted. The patient became drowsy on the evening of February 3; his tongue was dry, and the non-protein nitrogen content of the blood was 88 mg. per 100 c.cm. Five hundred c.cm. of 4.285% sodium sulphate with 10% glucose in normal saline was given intravenously by the drip method. The following morning the patient passed three ounces of rather thick reddish-brown urine, followed later in the day by gradually increasing amounts of macroscopically normal urine. Renal function tests performed some days later revealed no impairment of concentrating power.

The response to the intravenous administration of sodium sulphate solution is worthy of note in view of the successful application of a similar solution in Mr. J. C. Leedham-Green's case.—I am, etc.,

Liverpool, April 29. J. ROWLAND HUGHES.

Sulphonamides in Diphtheria

SIR,—I read with interest Drs. A. Kefalas and M. Goldin's letter (April 26, p. 648) on their experience of the value of the sulphonamide group of drugs in the treatment of diphtheria. These should be of great value, especially in those cases complicated by an additional haemolytic streptococcal infection.

Dr. R. A. Q. O'Meara and Dr. P. A. McNally stated in a paper read before the Section of Pathology of the Royal Academy of Medicine in Ireland on February 14 that by combining sublethal doses of diphtheria toxin derived from the Parke-Williams No. 8 strain with relatively insignificant amounts of other bacterial toxins, effects can be obtained similar to those previously produced by combination of the classical diphtheria toxin with extracts of gravis strains. If guinea-pigs are inoculated subcutaneously with such mixtures they develop large swellings with increased local necrosis and later paralysis. Their work suggests, at least to me, that even the presence of a mild additional haemolytic streptococcal infection to the diphtheria already present seriously aggravates the condition.

My experience is that these complicated cases do well if treated with adequate serum and the proper dosage of the sulphonamide group of drugs. It is customary in other fevers to give a large dose of one of these drugs at the start, and subsequently to give smaller doses to keep up the concentration of the drug in the blood. Unfortunately, if these drugs are given orally in the usual dosages there will be a tendency in certain cases to set up vomiting, which may seriously jeopardize the patient's chances of recovery, especially as a diphtheria case is peculiarly liable to cardiovascular complications. These drugs should preferably be given by the intramuscular or the intravenous route. If this is undesirable, great care should be taken in giving the drugs by the mouth.—I am, etc.,

G. E. DONOVAN,
April 29. Medical Officer of Health, Gorseinon, Swansea.

"Heat Convulsion"

SIR,—Dr. S. E. Osborne's case of "heat convulsion" (May 3, p. 689) appears to be due to anoxia rather than to heat. Convulsions due to hyperpyrexia are usually marked by a temperature around 110° F., a hot dry skin, considerable cyanosis, and preceded by malaise, headache, and restlessness for a period varying from a few hours to a few days. The danger of anoxic states supervening during nitrous oxide anaesthesia is not sufficiently appreciated, but thirteen cases were reported and the literature reviewed by Courville in 1936.[1] Courville emphasizes that cyanosis is not a necessary prelude, and that in toxic states severe cerebral damage can be done by comparatively mild degrees of anoxia. The free perspiration, excessive salivation, tachycardia, twitchings of the facial muscles, and clonic movements of the limbs suppressible by barbiturates, form a typical picture of an anoxic state of moderate severity. The condition cannot be relieved by the administration of oxygen, since the cellular changes in the brain are irreversible, usually temporarily so, as in Dr. Osborne's case, but sometimes permanently so with lifelong dementia as a sequela.

One seems to be justified in assuming that in the present case the toxic state of the brain tissue rendered it especially

[1] *Medicine*, 1936, 15, 129, 245.

sensitive to anoxia and that it suffered damage of this type despite the proportion of oxygen inhaled. On the other hand, it is possible that a temporary fault in the anaesthetic apparatus resulted in more nitrous oxide being given than was intended.—I am, etc.,

Sutton, Surrey, May 3. A. M. SPENCER.

Paste for Burns

SIR,—The use of "euglamide" in the treatment of burns as described by Dr. J. M. Robson and Mr. A. B. Wallace (March 29, p. 469) has proved to be very successful. Since the publication of this article we have been using this paste regularly for all cases of second- and third-degree burns, and have noticed quick healing without development of sepsis. The number of cases treated was considerable, due to recent enemy action. It has now become almost a routine treatment. The same paste has also proved to be very useful for ordinary septic lacerated wounds and abrasions. We apply the heated euglamide paste directly to the septic area. This paste is of similar consistency to antiphlogistine and applied in the same way. The wound is usually clean after one to two days of treatment and healing takes place rapidly. We also use it for impetigo and other septic skin conditions. We have prepared a solution of 5% sulphonamide in equal parts of glycerin and vitaminized oil, which we use for packing large infected wounds. We have called it euglamide liquid, and find it satisfactory. Instead of albucid, the sulphonamide used by Robson and Wallace, we use sulphanilamide with satisfactory results.—I am, etc.,

April 24. E. FRANKEL, M.B., B.S.

Convulsion Therapy by Electricity

SIR,—Dr. Gerald Caplan (April 26, p. 647) surely applied a peculiar individual twist to the interpretation of my letter (April 12, p. 571). I did not state that the faradic shock method described by him (March 29, p. 479) was "fully investigated in the nineteenth century," but only that closely similar methods were then described. My very brief description of Allbutt's method was prompted only by the fact that the work was carried out in this country. For an early account of the uses of faradism I would refer Dr. Caplan to Erb's *Handbook of Electro-therapeutics*, translated by L. Putzel, London, 1883.

Objection is also taken by Dr. Caplan to my suggestion that the convulsion described by him might have been due to the summation of subliminal stimuli. These he states were applied at intervals of "twenty-four hours." Nowhere in Dr. Caplan's paper do I find the words "twenty-four hours" used, but he does state that "fifteen shocks of half a second's duration are given at intervals of half a second."

To Dr. Caplan's criticism that I am more familiar with the literature of the nineteenth century than of the present, I can only reply that I had not had a pre-view of the April number of the *Journal of Medical Science* when I wrote on March 31. Incidentally, Dr. Caplan has not yet produced evidence to show that electric convulsion therapy might give rise to brain lesions and lung abscesses, as implied in his generalization. The references quoted by him in his paper are concerned with the pharmacological convulsants. Surely Dr. Caplan's fears with regard to the serious import of vertical fractures have been set at rest by the conclusions of Drs. Cook and Sands, who are of the opinion that "there is no justification for allowing the risk of vertebral fractures to preclude convulsion treatment in suitable cases."

Dr. Caplan envies me my "good luck" in not having any complications with electric convulsion therapy. I might here state what seems to me a significant fact—namely, that I was less fortunate, when using cardiazol, for two patients sustained a fractured femur before this method had been in use for a year.

I must regard Dr. Caplan's concluding paragraph as the soft answer that "turneth away wrath," for I certainly have no objection to any form of scientific research that will throw some light on the problem of mental disease.—I am, etc.,

Warlingham, Surrey, April 30. JAMES S. MCGREGOR.

*** This correspondence is now closed.—ED., *B.M.J.*

Sims's Operation: Then and Now

SIR,—The profession is indeed greatly indebted to Prof. Chassar Moir for his learned address on the above subject (December 7, 1940, p. 773). Although it is believed that vesico-vaginal fistula is nowadays less common in the European countries, it is not so in the East, the reason being that here expectant women are slow to seek medical aid and that midwifery and gynaecology are not practised as a specialty. Here is a case in point.

One young woman, otherwise healthy and in the prime of life, after having undergone more than one operation for vesico-vaginal fistula without success, was leading a miserable life, discarded by her husband. When she was seen by me she was using a cone-shaped piece of soft wood for plugging the fistular opening, as advised by a local "leech." She was radically cured by me by an operation performed on her in 1935, and has been thus rescued from a "distressing and unsocial condition."

I have on a previous occasion (August 1, 1936, p. 260) written to your *Journal* on this operation, following an article by Mr W. Arch. Mein (June 13, 1936, p. 1207). In my experience three chief conditions are essential for the simple Marion Sims operation to be successful in the very first attempt. They are: (1) Free internal exhibition of a safe and reliable modern urinary disinfectant some days preceding and following the operation. (2) A large indwelling over-size rubber catheter, about 3/8 inch in diameter, nearly the size of a rectal or stomach tube. It must be remembered that the adult female urethral passage is dilatable to that extent with little pain or permanent damage, provided it is dilated with careful technique. (3) Avoiding unnecessary post-operative irrigation of the bladder. Irrigation, especially a forcible one, invariably leads to distension of the cystic wall, causing the lotion to force its way between the stitches. The over-size catheter permits ready and free flow of the urine, allowing the bladder to rest and remain nearly empty till the wound is healed permanently by primary or secondary union, according to the method of repair.—I am, etc.,

Colombo, March 10. I. DAVID.

Medical Planning Commission

SIR,—Many individual voices have been raised recently in discussion of the organization of medical services, and from these individual views, expressed in the medical press and elsewhere, it is evident that considerable apprehension exists.

We of the Sutton and District Medical Society have, at our recent meetings, been giving much time to free discussion of the problems that lie ahead. In this letter we wish, as a body, to bring our views before the profession, and to give expression to doubts and dissatisfactions that we believe to be widespread. We are a society of sixty members, comprising general practitioners, medical officers of health, specialists, and medical women, and can fairly claim to represent all branches of medical opinion in this area of Surrey. However divergent our professional activities and interests, we are substantially agreed on the following points:

(1) We would welcome such evolutionary changes as might be indicated by past experience and by present and future needs, but we view with some apprehension the suggestion, indeed the threat, of sweeping reorganization, perhaps without sufficient "ventilation" or adequate discussion or debate by the profession as a whole. And especially would we regret the handing over of the profession to bureaucratic control. We believe this would be an unhappy change for both the public and ourselves.

(2) We are impressed by the fact that the B.M.A. is regarded with indifference or distrust by numbers too great to be ignored. That such an attitude should exist is to be regretted, but we are convinced that this feeling is widespread and very real.

(3) The Medical Planning Commission is, we think, unrepresentative in character and undemocratic in origin.

(4) In view of the above we feel we must recognize that at the present time there does not exist any body which commands the confidence of the majority of the profession, or can justly claim to represent it.

(5) There is therefore an obvious need for such a body, to interpret medical opinion, and to speak and to negotiate with authority on its behalf.

(6) The British Medical Association seems to us to be naturally the body of choice, but essentially a revitalized Association, able to attract those of the profession without its gates and to inspire those within.

(7) We have, in common with many others, constructive proposals to offer as to the direction of medical progress, but it appears to us that the primary necessity is the formation of this body. Meantime, we consider it of the greatest importance that societies similar to our own throughout the country, or groups formed for this specific purpose, should bring these matters into discussion, and publish their views in the medical press. We feel this would be a real contribution towards the solution of our difficulties.—We are, etc.,

T. H. WHITTINGTON,
J. CRAWFORD,
Hon. Secretaries, Sutton and District Medical Society.

April 28.

SIR,—At a meeting of the Hampshire Local Medical and Panel Committees held on April 23 last, the objects and constitution of the Medical Planning Commission were fully discussed by my committee, and the following resolution was unanimously adopted: "This committee is of opinion that no findings of the Medical Planning Commission as at present constituted should be submitted to the Government for approval without the general approval of the body of the profession through the Local Medical Committees."—I am, etc.,

G. A. E. ROBERTS,
Hon. Secretary.

May 1.

Certificates by Medical Practitioners

SIR,—I was very pleased to see the Warning Notice by the General Medical Council regarding certification printed in your issue of April 19 (p. 600). I and my colleagues who hold posts as factory medical officers are having many difficulties thrust upon us as the result of lax certification. These certificates are usually presented to excuse the person from fire-watching, shift work, night duty, etc., and many of them, while they may seem reasonable to lay members of the management, are ludicrous in the extreme when subjected to the understanding eye of a fellow member of the profession. Many managements will not accept these certificates unless confirmed by the factory medical officer, and it is very often extremely difficult to confirm them "on soul and conscience," as they say north of the Tweed. The doctor who gives them and the doctor who receives them are therefore both placed in a very awkward position, and the subject of the certificate is placed in a bad psychological position also. He thereafter has a constant grouse, and this in turn affects his ordinary work.

As an example of the kind of certificate often received perhaps I may be allowed to quote one which was handed to me yesterday. It states: "Mrs. X is suffering from neurasthenic fits and Mr. X is unable to leave her alone at night."—I am, etc.,

J. B. WRATHALL ROWE.

April 23.

J. B. Sandoval (*Thèse de Paris*, 1940, No. 127), who records twenty-six cases in patients aged from 2 months to 62 years, states that *B. pyocyaneus* septicaemia, which was first described by Ehlers in 1870, is a very rare condition of which two forms may occur. The first form consists of a pure septicaemia without any appreciable manifestations at the site of entry and without secondary localizations, while the second form is a combination of septicaemia and pyaemia. The source of the disease may be the skin, especially in the child, and the intestinal tract in the adult. Initial cutaneous lesions are exceptional in grown-up persons, and when they do occur *B. pyocyaneus* does not play an important part and is merely a secondary infection. A predominantly hepatic localization in some patients may be explained by the lack of resistance of a liver which has been damaged by a previous infection. Drugs are of no value in the course of the disease.

Medico-Legal

CORONERS' WARTIME POWERS

The exceptional conditions of war have made it necessary to introduce a shorter procedure for the presumption of death in cases where the body of a person who is suspected to have been killed in an air raid cannot be found. By Regulation 30A of the Defence Regulations, when a registrar reports to a coroner that he has reasonable cause to believe that a death has occurred in consequence of war operations and that the body of the deceased has either been destroyed, cannot be found, or is in a position from which it cannot be recovered, or has been buried as that of a person unknown or as some other person, the coroner may hold an inquiry. He must give notice, to be posted in a public place, and he holds the inquiry without a jury and in private, unless the Home Secretary otherwise directs. If he finds the person to have died the finding has the legal force of a presumption of death made by leave of the High Court. The procedure will remove what would otherwise constitute impassable barriers of time and expense in the administration of the estates of air-raid victims.

AGREEMENT IN MEDICAL EVIDENCE

In a personal injury action there is much to be said for an arrangement by which the doctors on both sides can consult and if possible agree on the evidence concerning the extent of the injury which they will give in court. By so doing it is often possible to obviate the need for a number of medical men to give up several hours or days to attend as witnesses. The courts recognize this possibility and, in the preliminary proceedings, make provision for it in suitable cases. It is right, however, that the practice should be limited by the requirements of each particular case.

In a recent action[1] a workman had his right hand crushed in the rollers of a machine, and the sole issue in the action was the amount of damages. On the summons for directions the District Registrar made the usual order for the medical reports to be agreed between the parties if possible and, failing agreement, medical evidence to be limited to two witnesses on each side. Attempts were made without success to agree the medical reports, and when the action was heard the only evidence given was that of the workman and of a doctor called by him who said that the man's hand was permanently disabled and that in his opinion nothing could be done to improve its condition. Mr. Justice Croom-Johnson expressed disapproval of the calling of the doctor as a witness, taking the view that the medical reports should have been agreed. Disregarding the doctor's evidence he assessed himself the working capacity of the man and allowed him only £550 damages. On appeal, these damages were increased to £1,268 8s. The Lords Justices said that the judge had been wrong in law in following his own ideas rather than the evidence of the doctor, and his estimate had been entirely erroneous. It was very unfortunate, said Lord Justice MacKinnon, that a judge should discourage the calling of a doctor in such a case, as it was often of the greatest possible advantage that the doctor should be present and be subject to cross-examination, and in a position to explain what he had written in his report. Lord Justice du Parcq added that it was a great mistake to think that it was always useful to order the medical reports to be agreed and that this direction should always be included. In a case where prognosis was an important matter it was most desirable that a doctor should be present in court to answer questions which the judge might wish to ask, if for no other reason.

[1] Proctor v. Peebles (Papermakers), Ltd., *Times*, March 15.

It is obviously desirable that the court trying a personal injury action—or any other—should have the best evidence obtainable. It is not desirable that medical men should feel compelled to reach an agreement against their true judgment. Their Lordships' remarks applied, of course, to a case where there was no agreement. When an agreed statement is before the court the judge would doubtless be satisfied if one medical man were present to clear up any uncertainties that might arise.

FALSE DECLARATION IN WORKMEN'S COMPENSATION

A workman was incapacitated by nystagmus, and when examined by a surgeon on behalf of the employers he disclosed that he had previously suffered from the disease. The surgeon made a note to this effect in his report, and the employers began to pay compensation at the full rate of 30s. a week, although when he had first been employed by the firm in 1928 he had signed a declaration that he had never had nystagmus. He signed another similar declaration in 1933. In fact, as he admitted at the hearing, he had suffered from nystagmus at various times, had been incapacitated for various periods lasting over seven years, and had been medically certified five times as suffering from it. Section 43 (1) (*b*) of the Workmen's Compensation Act, 1925, lays down that if it is proved that the workman has at the time of entering the employment wilfully and falsely represented himself in writing as not having previously suffered from the disease, compensation shall not be payable. The county court judge found as a fact that his false declarations had been wilfully made. Nevertheless, he held that the payment and receipt of compensation constituted a "binding and concluded agreement" under the Act whereby all questions of liability between the parties were settled. The firm appealed,[1] but the Court of Appeal upheld the judge's award. There is, by Section 21, no difference in effect between an agreement and an award of a county court judge, and if an award or an agreement is recorded and registered in the county court they have precisely the same validity. An unrecorded agreement (such as this) is just as effective as an unrecorded award, and precludes both parties from raising anew any question which would have been relevant when it was negotiated.

The Services

MENTIONS IN DISPATCHES

Lieut.-Colonel A. H. Whyte, D.S.O., Lieut. (Temporary Major) P. H. Newman, D.S.O., and Lieut. J. M. Muir, D.S.O., R.A.M.C., have been mentioned in dispatches for distinguished services in the field.

EFFICIENCY DECORATION, TERRITORIAL ARMY

The Efficiency Decoration of the Territorial Army has been conferred on Colonel F. R. Sandford, M.C., and Lieut.-Colonel A. Swindale, R.A.M.C., T.A.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Captain ALFRED ANTHONY FERRO died of wounds on March 19. He was born in Malta in 1914 and was educated at the Royal University of Malta, graduating M.D. in 1937. He joined the R.A.M.C. soon afterwards, and was promoted captain in May, 1939.

Captain WILLIAM BRADFORD FOSTER died in Middlesex Hospital on April 15. He was born at San Francisco in 1913, the eldest son of Mr. and Mrs. W. D. Foster of East Molesey, and was educated at Cranleigh School and St. Bartholomew's Hospital, qualifying M.R.C.S., L.R.C.P. in 1937. In the following year he graduated M.B., B.S. of the University of London. He had held the posts of resident surgical officer at Worthing Hospital and resident medical officer at the Kent and Canterbury Hospital. He joined the R.A.M.C. early in 1939. He leaves a widow and one son.

The name of Captain CHARLES EDWARD MCCLOGHRY is included as "Died" in an Army Council casualty list published on April 30. He graduated M.B., B.Ch., B.A.O. of Queen's University, Belfast, in 1936, entered the R.A.M.C. as lieutenant in April, 1937, was promoted captain a year later, and saw service in Palestine. He had been a member of the British Medical Association since 1937.

The death from wounds of Lieut. JOHN MURDOCH MCKILLOP is announced in an Army Council casualty list published on May 2. He was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1938. His home was in Glasgow.

INDIAN MEDICAL SERVICE

A list of casualties in the Indian Army, published by the India Office, records the death of Captain GILBERT CHARLES RETZ, aged 28. He was born on September 10, 1912, and was educated at Trinity College, Dublin, graduating M.B., B.Ch., B.A.O. in 1937. After holding the post of house-surgeon at Macclesfield General Infirmary he entered the I.M.S. as lieutenant in 1938, being antedated one year. He joined the British Medical Association in 1938.

DEATHS IN THE SERVICES

Wing Commander FRANK PAUL SCHOFIELD, R.A.F. (ret.), lost his life by enemy action in London last month. He received his medical education at St. Bartholomew's Hospital, and qualified M.R.C.S., L.R.C.P. in 1920. Four years later he took the degrees of M.B., B.S. of the University of London. He had held the post of house-physician at St. Bartholomew's. In 1926 he entered the R.A.F. as flight lieutenant, was promoted squadron leader in 1934 and wing commander in 1937, retiring in 1939.

Captain GEORGE WHARTON KENDRICK, late R.A.M.C., died at Cheddar on April 26. He was the son of the late Dr. Kendrick of Bilston, and received his medical education at St. Thomas's Hospital, taking the M.R.C.S., L.R.C.P. in 1932. Entering the R.A.M.C. soon after qualifying, he became captain in 1934. He had recently served in India and was stationed at Benares, but had to leave the Service owing to ill-health.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Linacre Lecture will be delivered by Sir Walter Langdon-Brown, M.D., F.R.C.P., Emeritus Regius Professor of Physic, on Friday, May 30, at 5.15 p.m., in the lecture room of physiology, St. John's College. The title of the lecture is "From Witchcraft to Chemotherapy."

Applications for the Marmaduke Shield Scholarship in Human Anatomy are to be sent to the Registrary by May 20. The award will be made towards the end of June. The persons eligible are such undergraduates of not more than three years' standing from matriculation, and such Bachelors of Arts of not more than four years' standing from matriculation, as have completed the first examination for medical and surgical degrees and are qualified in anatomy and in physiology to proceed to the Final M.B. Examination, and have also obtained honours in Part I of the Natural Sciences Tripos with anatomy as one of their subjects. Women also are eligible. The scholarship is normally tenable for one year from the date of the award, but a scholar may be re-elected for a second year. The emolument is £100 a year.

UNIVERSITY OF WALES

Nancy G. Rogers has satisfied the examiners in Part II and has qualified for the Diploma in Public Health.

SOCIETY OF APOTHECARIES OF LONDON

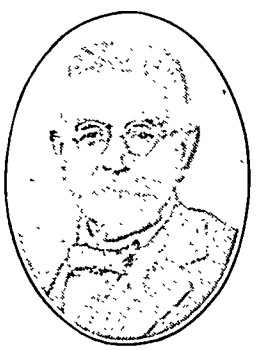
The following candidates have passed in the subjects indicated:

SURGERY.—C. A. Anderson, D. V. Bateman, G. H. Miles.

MEDICINE.—S. Hashim.

FORENSIC MEDICINE.—S. Hashim.

MIDWIFERY.—D. V. Bateman, A. H. Evans, P. R. Green, J. H. C. Hill, R. L. Skea, H. A. Worthy.



Obituary

JAMES HOGARTH PRINGLE, M.B., F.R.C.S.

Consulting Surgeon, Glasgow Royal Infirmary

By the death of Mr. Hogarth Pringle at his home in Killearn, Stirlingshire, on April 24, Glasgow has lost one of its most notable surgical personalities. For some years Mr. Pringle has been in indifferent health, and was occasionally laid aside, but he seemed courageously to defy illness till the terminal phase. He was in his seventy-eighth year.

Born in Parramatta, New South Wales, the son of G. Hogarth Pringle, M.D., F.R.C.S., he was educated at Sedbergh and Edinburgh University. He graduated in medicine in 1885, and became a member of the Royal College of Surgeons in 1888 and a Fellow in 1892. In the years following graduation he prepared himself for a surgical career by taking house-surgeonships in Edinburgh Royal Infirmary and Glasgow Royal Infirmary, and acting as clinical assistant in the gynaecological ward of the Edinburgh Royal Infirmary and assistant at the Royal London Ophthalmic Hospital. These home appointments were followed by study in Berlin, Vienna, and Hamburg, where he made lifelong friendships with masters of the standing of von Eiselsberg and Lauenstein. He was assistant to Macewen in Glasgow Royal Infirmary, and in 1896 was appointed surgeon to that hospital, retiring under the age limit in 1923. His long period of senior active service of twenty-seven years was recognized by the Board of Managers, who appointed him honorary consulting surgeon. In 1899 he was appointed lecturer in surgery and demonstrator in anatomy to Queen Margaret College, the college in Glasgow for women students before the University classes and the wards of the Royal Infirmary were open to them.

Pringle's interests extended over the whole field of surgery. He was essentially an individual worker, and spent almost the whole of his day in the wards. He was free from ambition to develop a large popular surgical practice. Fractures, at a time when that branch of surgery rather tended to be left to the house-surgeon, were treated entirely by himself, and his great interest in the subject and his mechanical skill in managing fractures are exhibited in a book, *Fractures and their Treatment*, published in 1910. He described original operations for umbilical hernia and inguinal hernia in the *Edinburgh Medical Journal* and in the *British Medical Journal*. A paper on the treatment of empyema was published in this *Journal* in 1905, and one on arrest of hepatic haemorrhage due to trauma in the *Annals of Surgery* in 1908. In 1913 he wrote a paper, published in the *Lancet*, on vein grafting for maintenance of direct arterial circulation: one such case, where a popliteal aneurysm had been removed and the arterial circulation re-established by means of a vein graft, aroused great interest when it was demonstrated to the Glasgow Royal Medico-Chirurgical Society. Other two contributions were also noteworthy: along with the late Prof. Teacher he demonstrated the occurrence of post-mortem digestion of the oesophagus, and at a London meeting of the British Association of Surgeons he described how sight might be saved by a timely operation in cases of haemorrhage into the optic nerve due to injury in the temporo-frontal region of the skull. Up to near the end of his life Pringle continued to follow up his cases, and to write minor papers with the late results of his work. At the time of his death he was actually engaged in working up his notes on some very early experiments on the cadaver to illustrate the mechanism of dislocation of the hip, as he was not convinced of the accuracy of the commonly accepted explanations.

Pringle was an original member of the British Association of Surgeons, and enjoyed his friendships with the members of the Chirurgical Club, founded by Moynihan, Robert Jones, and Stiles. He may be said to have lived for surgery and surgery alone. He was an extraordinarily thorough operator, with delicate manipulative and mechanical skill, and he was, like his master Macewen, a pathologist as well. He had not the gift of fluency in public speech and writing, but he possessed a direct, straight, and fearlessly critical mind, and no lack of fluency in private talk. A certain austerity of manner to strangers was not exhibited to those who had the privilege of his friendship, and members of the profession who turned to him in their illness had frequent occasion to appreciate his essential kindness of heart.

Prof. G. GREY TURNER writes:

Hogarth Pringle deserves to be remembered as one of the most progressive of the British surgeons of his day. As a young man he studied in Germany and Vienna and always kept in touch with the best of the Continental work. At the outset of his career he was associated with Macewen, and as long ago as 1888 he assisted that great man with pathological work in one of the side rooms which had been fitted up as a laboratory in the old Glasgow Royal Infirmary. In the picture which shows Macewen at work in the old theatre there in 1892, Pringle is a prominent figure near the head of the table. His stories of his association with Macewen were very vivid and clearly showed his indebtedness to that great master.

In his own work as surgeon to the Glasgow Royal Infirmary Pringle preserved a very open mind and was always anxious to give his patients the benefit of any new work which he considered worthy of trial. Long before the last war, in cases where he had excised strictures, he transplanted animal urethra to repair the defect and with encouraging success. He also employed arterial suture in some of his cases, using the Carrell technique, and transplanted portions of vein where arteries had been excised and with good results. But he deserves especially to be remembered for his own pioneer work in connexion with the treatment of melanotic sarcoma. As long ago as 1898, when this condition was looked upon as practically beyond surgical aid, he planned and carried out the operation which holds out the best chance of success. There were two cases, and in each there were secondary deposits in the lymph glands. Pringle kept in touch with the patients, and in 1937 in the *Lancet* he was able to report that they were both alive and well 38 and 31 years after his extensive operation. His plan for the control of the hepatic circulation in cases of severe haemorrhage should always be remembered, for this was certainly an original contribution to the management of the more serious abdominal injuries. In many other respects he did excellent work of a high order. His papers were always concise and direct, and he wrote a very good book on fractures.

A rather abrupt manner and a fierce expression sometimes created an unfavourable reaction which was certainly unjustified, for Hogarth Pringle was among the most kind-hearted of men and a delightful travelling companion. But the open sesame to his true friendship was a real interest in surgery unsullied by the slightest hint of sham or unwarranted publicity. Among that inner circle who appreciated his real worth he will indeed be sorely missed.

THOMAS H. W. ALEXANDER, F.R.C.S.ED.

Surgeon, Gray's Hospital, Elgin

We regret to announce the death, which took place on April 29 after an operation at Aberdeen, of Dr. Thomas Hood Wilson Alexander, one of the best-known medical practitioners in the north-east of Scotland. He was aged 63.

A native of Perth, he graduated M.B., Ch.B. at the University of Edinburgh in 1900 and was house-surgeon at the East Suffolk Hospital, Ipswich, before going for postgraduate study to Berlin, where he acted as clinical assistant at the Charité Hospital. He began practice at Elgin nearly forty years ago, and his services as a surgeon were in demand throughout

north-east Scotland and the Hebrides as well. During the last war he served with the rank of Major R.A.M.C.T.R., as surgical specialist and officer in charge of the surgical division of various medical units of the Expeditionary Force, and was present at the Salonika operations. He took the F.R.C.S.Ed. diploma in 1918. At Elgin Dr. Alexander was surgeon to Gray's Hospital, medical referee under the Workmen's Compensation Act for Elgin and Nairn, consulting surgeon to the Stephen Cottage Hospital, Dufftown, and surgical specialist to the Ministry of Pensions Appeal Board. Outside professional duties his interests were varied and he devoted time and thought to public work; he was a J.P. for Morayshire and for some time chairman of the Moray Education Authority. He joined the British Medical Association in 1901, represented his Division in 1914, was a member of the Scottish Committee in 1920–1, and president of the Northern Counties of Scotland Branch 1931–2.

W. M. SCOTT, M.D.

"A." writes:

The *Journal's* notice of W. M. Scott reflected a characteristic of its subject in the modesty with which his accomplishments were set forth. Actually Scott was one of the most experienced bacteriologists in the world as regards the organisms of epidemic diseases, and his help in identifying types of bacteria and in discovering the origin and course of outbreaks was given with the greatest care and friendliness to bacteriologists and others in every part of the country, and to many his first service of this kind was volunteered. The laboratory of the Ministry of Health in which he and Fred Griffith worked was fantastic in discomfort and lack of good equipment, but both of these men overcame the disabilities imposed on them, and the absence of clerical assistance led Scott to write his reports on specimens sent to him in the form of letters which combined instruction with information. The last medical discussion in which I heard him take part—more than a year ago—was on food poisoning by the Salmonella organisms, in the study of which he was one of the foremost in the world. On this occasion he was a guest speaker at the Royal Society of Medicine, and he began his contribution with a sincere apology for the small offering he had to bring. He seemed really distressed by this feeling, and perhaps like some others I wondered whether the upheaval of his work by the war had prevented his making anything but a hasty preparation of material. Admittedly I should have been wiser than to share his diffidence in his work, and he expounded experiments of practical value which would have been for many people the contented occasion of an independent contribution to a journal. His writings in official reports and elsewhere combined accuracy in the latest scientific details with practical use in the detection of epidemics, and similarly his interest in his work merged with his interest in mankind and its morals and its manners. His popularity with his colleagues in this country was buttressed by his acquaintanceship with bacteriologists in many lands and by the important part he took in the International Society for Microbiology and its successive congresses. At his home in Dulwich he and Mrs. Scott and their family gave the liveliest and most generous hospitality to many, and these as well as other readers of the *Journal* deeply regret the loss which his death has caused to his relatives, his friends, and to the work which he was brilliantly executing.

Dr. JOHN L. BUNCH, who died suddenly at Teignmouth on April 22, practised for many years in London, largely as a dermatologist, and had been a member of the British Medical Association for forty-three years. A student of University College, London, he graduated B.Sc.Lond. in 1890 (qualifying for a university scholarship), took the M.B., B.S. in 1893, the M.D. in 1895, and the D.Sc. and M.R.C.P. in 1898. As an undergraduate he won a university exhibition and gold medal in physiology; also the Atchison scholarship and Filliter exhibition in pathology at University College, where he was for a time assistant demonstrator of anatomy after serving as house-physician and house-surgeon at U.C.H. On returning from postgraduate study in Paris and Vienna Dr. Bunch was appointed assistant physician to the German Hospital in London and to the Mount Vernon Hospital. Later he was appointed physician for diseases of the skin at the Queen's Hospital for Children and physician to the Hospital for Diseases of the Skin in Leicester Square. He was a past-president of the London Dermatological Society and wrote the article on pruritus and itching diseases of the skin in Hutchison and Collier's *Index of Treatment*, as well as papers in the *British Journal of Children's Diseases* and the *British Journal of Dermatology and Syphilis*.

The death of Dr. MORGAN JOHN MORGAN of Aberystwyth in his 77th year has caused widespread regret both in the town and in the countryside of North Cardiganshire. A student of Guy's Hospital, he qualified with the L.S.A. and the M.R.C.S., L.R.C.P. in 1889, and ten years later took the D.P.H of the English Royal Colleges and the M.D. of Brussels. As a young man he returned to his native town as house-surgeon to the Aberystwyth Infirmary and Cardiganshire General Hospital; after this he began general practice on his own and did very well, and for nearly fifty years served the neighbourhood faithfully. Dr. Morgan has been well described as a beloved family doctor, upon whom his patients leant heavily in time of trouble. He was for many years honorary surgeon to the Aberystwyth Infirmary, and during the last war was medical officer to the local Red Cross Hospital. He had been a member of the British Medical Association for nearly half a century. Engrossed in his profession, Dr. Morgan found no time for public life, but he took a keen interest in the affairs of the town, where he was such a familiar and respected figure.

Dr. JAMES SALWEY, elder son of the Rev. Geoffrey Salwey, rector of Botley, near Southampton, was injured by enemy action while attending to air-raid casualties with great devotion, and died in hospital soon after admission. He was not yet 25 years of age. Educated at Epsom College and the Middlesex Hospital, he qualified as M.R.C.S., L.R.C.P. last October. He was fond of sailing and other outdoor sports, and had been secretary of the Middlesex Hospital Musical Society.

The following well-known foreign medical men have recently died: Surgeon-General Rear-Admiral WILLIAM CLARENCE BRAISTED, United States Navy, retired, and president of the American Medical Association 1920–1, aged 76; and Senator GIUSEPPE TUSINI, emeritus professor of clinical surgery at Genoa and author of works on echinococcus disease of the liver, actinomycosis of the foot, and cysts and tumours of the pancreas.

Medical Notes in Parliament

Employment of Alien Doctors

Answering Colonel Arthur Evans on April 30, Miss HORSBRUGH said she did not know how many friendly and allied alien doctors with special qualifications were still unemployed or how many Czechs with medical degrees in their own country were studying for English degrees, or whether there was a surplus of Army doctors with the Czech Army. Colonel EVANS asserted that special scholarships had to be granted to enable these alien doctors to study. He asked Miss Horsbrugh to take steps to absorb all unemployed doctors, irrespective of nationality, and to permit alien doctors already qualified in their own country to practise without taking English degrees.

Miss HORSBRUGH replied that the Medical Practitioners (Temporary Registration) Order, 1941, provided a wide field of employment for American and Allied alien doctors and refugee doctors of enemy nationality in hospitals and other approved institutions without the necessity for obtaining British medical qualifications. Their absorption into this service was proceeding steadily. Linguistic and other difficulties made it inadvisable to allow these doctors to engage in domiciliary practice.

Sir HENRY MORRIS-JONES said there was a breakdown in the employment of friendly Allied and alien doctors. In this country there were 700 such doctors, yet 1,000 doctors were asked from the United States. Miss HORSBRUGH gave an

assurance that all alien doctors would be used in hospitals and institutions. She added that the general scheme for reorganization of medical practitioners was going on. Sir Henry Morris-Jones said he would raise the matter again.

Mr. ERNEST BROWN told Miss Rathbone on May 1 that he would not defer arrangements for bringing over American doctors to this country until the medical service had absorbed other fully qualified foreign doctors now here. He said the American doctors were needed mainly for service with the Forces, while alien doctors of the European nationalities covered by the Medical Practitioners (Temporary Registration) Order, 1941, were needed mainly for employment in civil hospitals and institutions. The employment of the two classes could therefore proceed concurrently. At the moment 100 alien doctors had been found employment and notified to the General Medical Council for registration. Another 150 were under consideration for employment. The Government required all the doctors it could get. Sir FRANCIS FREMANTLE asked whether Mr. Brown was convinced that the Central Medical War Committee was doing all it could to get these people employed.

Mr. G. STRAUSS asked that friendly alien doctors in the Pioneer Corps should be given medical work and that the British Medical Association should not be allowed to stand in the way of their employment.

Mr. BROWN said these doctors would certainly be given a chance. He was not aware that the British Medical Association had any intention of standing in the way. The Central Medical War Committee was doing its best in this matter and had the hearty co-operation of the British Medical Association. Sir FRANCIS FREMANTLE remarked that the British Medical Association had nothing to do with this matter.

Feeding the Nation

Introducing, on April 30, an Estimate for the Ministry of Food, Major LLOYD GEORGE said that in 156 towns 299 communal restaurants had been approved in addition to 170 London meals centres operated by the L.C.C. and 280 evacuee centres now operated as British restaurants open to the general public. During the last year the consumption of liquid milk rose by 14%. That demand could not be met in winter, and the Central Milk Distribution Committee had been asked to ensure a saving of 15% in consumption of milk. There would not, however, be any cuts in the milk supplies to people who took one pint or less per day. Dairymen had been instructed to respect needs of illness. This scheme did not affect the national priority classes such as schools, hospitals, and persons suffering from certain illnesses.

Sir ERNEST GRAHAM-LITTLE said a most important question was provision of bread which contained the wheat germ and the salts of the wheat germ. The fortified loaf, which had been discussed in the Food Estimates debate of July, 1940, was now much discredited. Milk, vegetables, and fruit, the staple sources of vitamins and salts necessary for nutrition, were difficult for the poorer classes to obtain. Bread would be the principal source of vitamins for the population generally. That the reinforced loaf was a proper substitute for the wholewheat loaf was a mistaken proposition. All that was proposed to do with the reinforced loaf was to add an inadequate quantity of vitamin B. In 1918 a Committee of the Royal Society had pronounced absolutely in favour of the wholemeal loaf.

Diabetics' Rations.—In reply to a question by Sir Ian Fraser on April 22 Major LLOYD GEORGE said that on the recommendation of the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council, an independent body of medical experts by whom Lord Woolton was guided, he had arranged for diabetics to receive two extra meat and two extra butter and margarine rations a week in place of their sugar ration. Lord Woolton understood that these extra allowances enabled persons suffering from diabetes mellitus to obtain an adequate diet, and under the present food restrictions no other special arrangements needed to be made

Rations during Pregnancy.—Dr. HOWITT suggested on April 30 that the Ministry of Food should grant an extra half-ration of butter and an extra half-ration of sugar to all pregnant women for the last six months of pregnancy and for six months after delivery if the mother nursed her child. Major LLOYD GEORGE said the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council advised that no extra allowances of any rationed food were necessary for expectant mothers. As soon as a birth was notified a child's ration book was issued by the local food office, the rations being intended for the use of the mother.

Notes in Brief.

Many stamped national health insurance cards have been lost or destroyed by enemy action. All approved societies and local authorities have been specially advised of simplified procedure to be followed in reporting such loss or destruction to the Central Department, so that credit may be allowed for the missing stamps with the utmost speed.

To mitigate the danger of infection Mr. Brown has decided that not more than forty-eight children shall be accommodated in each dormitory of the national camps.

Mr. E. Brown told Mr. Viant on April 8 that six cases of post-vaccinal encephalitis came to the notice of the Ministry of Health during 1939, of which three were in soldiers.

The Minister of Food has under consideration the special need of young children for such foods as eggs and fruit.

The number of deaths from cancer in England and Wales registered during 1939 is provisionally returned as 69,001.

Medical News

The one hundred and fifth annual general meeting of the Royal Medical Benevolent Fund will be held at the Royal Society of Medicine, 1, Wimpole Street, W., on Wednesday, May 14, at 12 noon, with the president, Sir Thomas Barlow, in the chair.

The next meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, W.C., on Saturday, May 17. At 2 p.m. there will be private business, and at 2.30 p.m. a discussion on "The Employment of Women in Industry," to be opened by Dr. M. L. Dobbie-Bateman, Miss F. I. Taylor, Dr. L. S. Swanston, and Dr. Graves Peirce.

The Glasgow Branch of the Chartered Society of Massage and Medical Gymnastics will hold an extraordinary general meeting in the Hall of the Scottish Nurses' Club, 203, Bath Street, Glasgow, on Thursday, May 15, at 7 p.m., for a discussion on "Occupational Therapy in Relation to Physical Therapy," with special reference to re-education after injury. The discussion will be opened by Dr. Anna Broman, medical physiotherapist; Miss Amy de Brisnay, occupational therapist; Mr. James Patrick, F.R.C.S.Eng., surgeon in charge of the Rehabilitation Department, Glasgow Royal Infirmary; and Mr. G. H. Stevenson, F.R.C.S.Ed., surgeon, Glasgow Royal Infirmary. A cordial invitation is extended to members of the medical profession to attend and take part in the discussion. Those desirous of contributing are asked to communicate with the honorary secretary, Miss Elizabeth A. Watson, C.S.M.M.G., 9, Berkeley Terrace, Glasgow, C.3.

The B.B.C. announces a broadcast talk to schools on Thursday, May 15, at 2.40 p.m., on Sir Ronald Ross's work in the conquest of tropical disease; also two talks in a new series on science and the fighting man: on May 13, "The Unseen Enemy: Modern Methods of Fighting Germs in War," and on May 20, "Blood in Bottles: How Modern Methods of Blood Storage and Blood Transfusion are Saving Life," both at 3.30 p.m.

Lieut.-General A. G. L. McNaughton, General Officer Commanding 1st Canadian Corps Overseas Force, and president of the National Research Council of Canada, will read a paper entitled "Research in Canada" on Tuesday, May 13, at 2.30 p.m., at the Institution of Electrical Engineers, Victoria Embankment, W.C.

In 1939 Argentine had 11,807 doctors, and 426 hospitals, of which 42 were national, 114 municipal, 50 provincial, 187 owned by welfare organizations, and 16 belonged to foreign colonies. There were 47,371 beds for general diseases and 23,668 for special diseases. In Buenos Aires there were 5,391 doctors and 37 hospitals.

The Board of Trade has issued an open Licence (S.R. and O., 1941, No. 554) authorizing any person registered under the Limitation of Supplies Order in Class 1 to supply without limitation as from the date of the licence, April 22, 1941, abdominal belts specially designed for post-operative use, the following: (1) suprapubic drainage belts, (2) colotomy belts, (3) belts for appendicectomy, (4) belts for nephrectomy.

The following committee have been appointed for four years to advise the Government of the Union of South Africa concerning leprosy research and other matters relating to leprosy in the Union: Dr. P. Allen, Secretary for Public Health and Chief Health Officer for the Union; Dr. E. H. Cluver, Director of the South African Institute for Medical Research; Prof. W. F. Rhodes, Capetown; Prof. W. H. Crain, Johannesburg; Dr. A. Pijper, Dr. A. J. Orenstein, and Dr. K. Bremer, M.P.

Vitamins, vitamin concentrates, and vitaminized oils are regarded as put up for medicinal use and as chargeable with Purchase Tax when they are put up for use by injection, but not otherwise.

Dr. Alfred Blacklock, professor of surgery at Vermont, has been appointed to the chair of surgery at the Johns Hopkins University. He is the third incumbent of the chair, the first being the late Dr. William S. Halstead, who was succeeded by Dr. Dean Lewis.

The Robert Jones Medal and British Orthopaedic Association Prize for 1940 have not been awarded.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The returns for the week under review show that there was a substantial decline in the incidence of all infectious diseases with the exception of enteric fever. The number of cases of scarlet fever was the lowest for forty weeks, and of diphtheria for the past thirty-two weeks. The decline in the number of notifications of measles was general, but there was one notable exception: 97 cases were reported during the week in Corby U.D., Northampton; this area had no cases of measles during the three preceding weeks. Whooping-cough, which had an increasing incidence during the past three weeks, declined by 1,030 cases. In Scotland, where the returns for whooping-cough have been dominated by the epidemic in Glasgow, the cases were one-half of those recorded a fortnight before.

Dysentery

The outbreak in the district of Hemel Hempstead, Herts, has begun to subside: 25 cases were notified as compared with 79 in the previous week. The infection has been reported from the adjacent districts of Berkhamsted and Watford, where 20 and 5 cases respectively were notified. Cases were reported in several fresh districts, the chief of the new outbreaks being in Berkshire, Hungerford R.D. 5; Cornwall, Bodmin M.B. 6; Surrey, Banstead U.D. 5; Lancashire, Liverpool C.B. 6. An increase occurred in London, where the cases rose from 5 to 15. Chelsea with 8 and Wandsworth with 4 cases were the boroughs responsible for the rise.

Quarterly Returns of the Registrar-General

The quarterly returns of the Registrar-General for England and Wales, covering the fourth quarter of 1940, include a provisional summary for the year. The death rate for 1940 was 14.3 per 1,000. This was 2.2 above that for 1939 and reverts to the mortality level of two decades ago. Two-thirds of the increase in deaths occurred in the first quarter, when weather conditions were very severe and there was a considerable amount of influenza. The birth rate of 14.6 per 1,000 was 0.3 below the figures for 1939. Infant mortality was 55 per 1,000 live births, and was 5 above that for 1939 and 2 above that for 1938, but was lower than in any year before 1938. Stillbirths were 36 per 1,000 total births, and the number recorded, 22,648, was the lowest on record. The marriage rate for 1940 was 22.6 per 1,000, and was the highest on record.

No. 15

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 12.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Potassium Content in Schistosomiasis

Dr. F. GORDON CAWSTON (Durban) writes: Is it possible that persons living in districts infested with schistosomiasis possess a lower proportion of potassium than is common in Great Britain, or might it be that the presence of the adult worms interferes with the potassium content of the host's tissues? There would seem to be some such explanation needed to account for the preference in the Tropics of the potassium salt to its sodium equivalent, for those whose study of therapeutics is largely confined to cool climates regard the sodium as being less toxic.

Intermittent Polyuria

DR. ALEXANDER FRANCIS (London) writes: "G. A. G. S.'s" intermittent polyuria (April 26, p. 658) is almost certainly a manifestation of vasomotor instability, and is comparable with an attack of asthma. A too-active blood supply to a particular part may produce symptoms in the area, and so we get asthma, hay fever, polyuria, colitis, etc., according to the region affected. I have proved that these troubles can be overcome by stabilizing the flow of blood throughout the system. "G. A. G. S." would obtain marked relief from the simple remedy of rubbing the surface of the body for five minutes night and morning. This has more effect than any amount of exercise or "physical jerks."

Ulcer of the Mouth

DR. E. U. MACWILLIAM (Bexley, Kent) writes: The following case note may be of interest to others; any suggestions as to aetiology of the condition described would be welcomed by me. Female, aged 58, retired secondary school teacher, valvular disease of the heart following three attacks of rheumatic fever about twenty years ago; severe congestive failure since September, 1939. In June, 1940, an ulcer appeared on the right side of the tongue, followed by two others, one on the left edge of the tongue and the others on the inside of the left cheek. These two latter did not develop much. The primary ulcer steadily progressed. At a fairly early stage it suggested a gumma; later it became a sloughing mass. More than half of the tongue had been destroyed, and the destructive process extended into the floor of the mouth. Three very severe haemorrhages took place, in two of which the patient appeared to be on the point of death. By way of treatment novarsphenamine was given intravenously (although the Wassermann reaction was negative); iodine, acriflavine, sulphanilamide powder, etc., were applied locally; and various mouth-washes were used. None of these had any beneficial effect. Finally I gave the following rather old-fashioned mouth-wash, and the whole thing, except for the loss of tissue, cleared up as if by magic: ℞ Pot. chlor. 3j, acid. hydrochlor. fort. 3ss; let the acid act on chlorate for three minutes, then gradually, with shaking, aq. ad 3vj. It was not possible to have pathological investigations.

Income Tax

Repayment of Borrowed Money

"LAMBDA" obtained certain advances to enable him to complete his studies. He is now in the R.A.F., and is repaying the loans in monthly amounts. Can he claim any allowance against the assessments on his pay?

*** The repayments are of a capital nature, and no allowance can be claimed for income-tax purposes. An allowance can, however, be claimed in respect of the amount of *interest* paid to the bank in each financial year—ending April 5. The bank will supply a certificate of the amount on application, and the certificate should be sent in to the Assessor's Department of the R.A.F. asking for an allowance to be set off against the tax assessed on pay.

Demolition of House and Contents

"BOMBED" inquires to what extent the loss of house, clinic, and contents can be claimed for income tax purposes.

*** The loss as such is not an allowable deduction, but the cost of replacing professional equipment (but not the premises) can be deducted to the extent to which it is not covered by insurance or other claims to indemnity.

LETTERS, NOTES, ETC.

Blood Pressure and Peptic Ulcer

DR. E. SAKOSCHANSKY (Southampton) writes: I have read with great interest the article on digestive disorders in the Forces by Lieut.-Colonel J. Gibson Graham and Captain J. D. Olav Kerr (March 29, p. 473). They suggest that the quickening tempo of modern life is related to the increasing occurrence of the dyspepsias, especially peptic ulceration. In connexion with that statement it occurred to me that it would be interesting to see what the level of the blood pressure was in cases of peptic ulceration. I have been struck on a number of occasions by the low blood pressure in cases of peptic ulceration. This low blood pressure would account for the mental instability, fatigability, and asthenia of many of the cases of gastric ulcer, and would account for Colonel Graham's statement that the severe physical strain and irregular meals before evacuation—from France—had an adverse effect. I think this blood-pressure reading is often helpful in distinguishing between "gastritis" cases (such as, for example, those due to the upset caused by air raids) and organic cases. And it may be added that this low blood-pressure reading had been noted in cases of gastric carcinoma (Thiele, W., *Epitome*, June 4, 1938, p. 458).

Primitive "Closed Plaster" Treatment

DR. ERNEST CULPIN writes from Brisbane: One characteristic of the medical profession appears to be the jealously guarded right of recognition of those who have been the first to introduce any particular method of medical diagnosis or treatment. With respect to the "closed-plaster treatment of wounds" I desire to bring forward the claims of my old friend "Binghi." It is thirty-five years since I had the privilege of observing this time-honoured method of treatment of badly lacerated and infected wounds by "Binghi" when in North Queensland. "Binghi's" technique was simply to cover the wound with a thick coating of mud, which rapidly dried, and to leave it alone. Results as to the healing of the wound were excellent, but in the case of fractures of long bones, of which I saw only one, although union was sound deformity was pronounced. The Australian aborigine—that is, "Binghi"—has apparently been using this "closed-plaster treatment of wounds" for centuries with excellent results. Incidentally, before contamination with the white and yellow races "Binghi" was far superior to European races in respect to public and private morality, and although it had developed in a very divergent direction his intelligence was of a superior order.

Students and the Planning Commission

MR. PETER F. KENNISH writes: I am a student of a London hospital and I wish to express my views on Mr. H. S. Souttar's letter (April 12, p. 569). He makes two points: (1) That members of the Medical Planning Commission are representative. Medical students are not represented and have never been consulted in the matter; the ages of the youngest members of the Commission indicate that they qualified at least twenty years ago and are therefore out of touch with my generation. (2) That there are eleven members "under 45" and that in political life this is considered young. This Commission is concerned with the medical profession, not with politics; few people are grateful for the pass to which the country has been brought by our political "youngsters." Students and men recently qualified are those who will be most deeply affected by the results of the Commission's work. They are keenly interested in the future of their profession, but evince little enthusiasm at the prospect of its being planned by a group of people with whom they have no contact. I suggest that the medical schools have a right to be represented by at least one student or recently qualified man. Lack of experience would be more than adequately balanced by a fresh mind and a less crystallized outlook.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 10 1941

MEDICAL ATTENDANCE ON AIRMEN AND AIRWOMEN ON LEAVE

The Air Ministry has added a new paragraph to Order No A 828, which was published in the *Supplement* of February 22, page 21. The Order now reads as follows:

1. In accordance with para. 1400 of K.R. and A.C.I. and the instructions on the reverse of Form 295, it is incumbent on all airmen who fall sick while on leave to report if practicable to the nearest naval, military, or Air Force medical establishment or to a civil hospital included under the Emergency Medical or Hospital Schemes of England and Wales, Scotland, or Northern Ireland, showing their passes.

2. Personnel residing more than two miles from a Service medical establishment and unable, owing to their condition, to visit an Emergency Medical Service Civil Hospital although this is within two miles may make application to a civilian medical practitioner, to whom the instructions on the reverse of Form 295 will be shown, and will immediately inform their unit of any such application.

3. If personnel apply to a civilian medical practitioner when it is practicable to apply to the medical officer of a Service medical establishment or to attend at an Emergency Medical Service Civil Hospital, they will render themselves liable for such expenses as may be incurred.

4. To enable personnel to obtain the name and address of the appropriate Emergency Medical Service Civil Hospital nearest to their place of residence while on leave, arrangements have been made for this information to be obtained on request from officers in charge of local air-raid posts.

4A. Claims for payment rendered by a civilian medical practitioner in respect of medical attendance or treatment afforded to personnel on leave will be accepted as charges against public funds unless it has been clearly established, after investigation by the unit concerned, that payment is the liability of the individual, when he or she will be so informed.

5. The provisions of this Order apply also to airwomen.

The Air Ministry also states that a certain amount of difficulty is being experienced by the Air Force authorities in connexion with medical certificates granted in respect of airmen and airwomen by medical practitioners who are called in to attend them when they fall ill on leave. It is essential for medical practitioners to certify on these occasions that the individual is fit or unfit to travel. This is required because if they are fit to travel it is necessary for airmen or airwomen to return to their units or to attend a Service hospital to receive treatment there. Failure to record this information on the certificate involves a considerable amount of correspondence between the Air Force authorities and the medical practitioners concerned, and valuable time would be saved on both sides if certificates were invariably to be made out in accordance with the instructions which are fully explained on the back of each airman's and airwoman's leave pass.

PAY OF CIVILIAN MEDICAL PRACTITIONERS

The War Office has now announced certain alterations in the rates of pay for civilian medical practitioners engaged by the Army. The letter issued to commanding officers is as follows:

"I am commanded by the Army Council to inform you that they have had under consideration the remuneration of certain civilian medical practitioners employed whole-time or part-time and paid under the terms of War Office circular letters of September 5, 1939, and February 8, 1940, No. 24 General/62 (F.2.d). Whenever possible civilian medical practitioners so employed should use drugs and dressings provided by the public, but, where this is not practicable, the Council authorize the increase of the appropriate whole- or part-time rate payable under War Office letter of September 5, 1939, by a sum assessed on the basis of approximately 1s. a day for each 120 persons under his care.

The Council have also decided to increase with effect from October 1, 1940, the pay of civilian medical practitioners employed on a capitation basis under Article 290 Pay Warrant to the following rates:

If there are less than 10 persons	£6 17s. a year
If there are 10 persons or more, for every complete 25 or portion of 25, provided that the total emoluments for all services, exclusive of the examination of recruits and reservists, shall not in any instance exceed £1 10s. for any one day	£13 14s. a year

The maximum daily payment for all services will be increased to £2.

DOCTORS AND FIRE PREVENTION DUTIES

The Civil Defence Duties (Compulsory Enrolment) Order, 1941, gives local authorities power to enrol local residents for compulsory fire prevention duties in the area. As a result of representations made by the British Medical Association the Ministry of Home Security has promised to take steps to exempt medical practitioners from registration and enrolment under this Order.

The Fire Prevention (Business Premises) Order, 1941, compels occupiers of business premises to make arrangements for fire prevention duties, but it is expressly stated that this Order does not apply to "any premises occupied by any person partly as his dwelling house and partly for the purposes of his business, trade, or profession." This proviso automatically excludes from liability under the Order medical practitioners whose surgeries are at their place of residence. A practitioner who has a lock-up surgery or lives away from his surgery must make arrangements for the protection of the premises. He may employ someone to undertake fire prevention duties, or, if this is not possible, he may apply to the local authority for a watcher from the local pool.

Medical practitioners who are employed by a local authority or by a hospital management are not exempt from the Fire Prevention (Business Premises) Order, 1941, when this Order is applied to their area by the Regional Commissioner. All male persons employed on the premises are liable to take their turn in the rotas of duty. Exemption is granted under the Order to persons working a sixty-hour week or longer on vital work, and exemption may be applied for to the appropriate authority on behalf of persons engaged outside their normal working hours in other branches of the A.R.P. organization. If a medical practitioner employed by a local authority or in a hospital is liable to be called upon at any hour to attend to air-raid casualties it may be unreasonable to expect him to undertake fire prevention duties as well. The position of the individual practitioner concerned would have to be taken into consideration, and it is suggested that where a practitioner is already liable to undertake additional medical work outside his usual working hours in connexion with air raids his employing authority should be asked to approach the appropriate authority with a view to releasing him from fire prevention duties.

G.M.C. FINANCES

The number of £5 registration fees paid to the General Medical Council during 1940 showed a sharp reduction on that for the previous year. In England it fell from 1,435 in 1939 to 1,330 in 1940; in Scotland from 692 to 670; and in Ireland from 362 to 315. The biggest fall was in the number of colonial and foreign practitioners, of whom 483 paid the £5 registration fee in 1939 and only fifty-two in 1940. The total reduction in income from registration fees amounts to £3,356. As against this and other reductions in receipts, the expenditure of the Council is down by some £1,600, largely due to the compression of the summer session into two days and of the winter session into three. The fees and expenses of members of the Council are only two-thirds of what they were the year before, which itself was an economical year. The Council, by reason of the number of its members and the fact that they come from all parts of the British Isles, is commonly said to be the most expensive of disciplinary bodies. A day's session in fees alone works out at just under £200, and in addition there are hotel and travelling allowances. The Council, however, is in an excellent financial position. The surplus in the hands of the English Branch Council amounts to over £63,000, and of the Scottish Branch Council to nearly £23,800.

WAR DAMAGE ACT

The Medical Insurance Agency states that it has now been decided by the authorities that the principle of average will not be applied to insurances under the (voluntary) chattels sections of the War Damage Act. It follows that there is no compulsion to insure for the full value of goods of this type, though doubtless it is wise that this should be done.

Correspondence

State Medical Service

SIR,—The correspondence in the *Journal* appears now to be concentrated on the work of the Medical Planning Commission rather than, as at first, on its personnel. And the salient feature of this later phase is, without doubt, the question of a State Medical Service. What is the attitude of the public? In my opinion the public will follow its leaders in this matter, and its leaders of one political party will introduce such a service at the earliest available opportunity, provided there is no evidence of strong and united professional opinion against it, and the other political party will also introduce it, though less wholeheartedly, if there are indications of a large professional opinion in its favour. The crucial question therefore is, What does the medical profession want? Up to now the advocates of a whole-time service in your correspondence seem to have had the best of it; but are they merely the more vocal? Do they represent the mass of the profession, notoriously inarticulate until a crisis arises?

For some years past I, as others, have been convinced that there is a strong and growing opinion, especially among our younger colleagues, in favour of a whole-time service. Private talks, impromptu discussions at meetings, letters from various correspondents have all given me this impression. Moreover, whatever their own opinion for or against, practically all with whom I have spoken are agreed that, whether we like it or not, such a service is inevitable. And this view has been gathering strength quietly, almost imperceptibly, during the last few years. It has required the war to accelerate this process, and the appointment of the Planning Commission to bring the question right into the open.

But much if not all of this is merely presumption, not based on any concrete evidence. I have been very anxious to secure such, and recently have carried out a small experiment of my own. I sent a short circular letter to every medical practitioner in my own county of Derbyshire, with the exception of the Service members, with whom, at that time, I was unable to get into touch, asking what their reactions would be to a proposal for a State Medical Service, such, for example, as that outlined by Dr. Pybus in the *Supplement* of March 15.

The results of the inquiry up to date (answers still coming in) are as follows:

Practice	For		Against	
Consultants and Specialists	11		2	
Public Health Service	22		2	
Hospital Residents	2	121	1	72
General Practitioners	86		66	
Unclassified	—		1	

Age Group	For		Against	
25–35	21		11	
35–45	54		20	
45–55	29	121	23	72
Above 55	17		17	
Unclassified	—		1	

The inquiry was limited to one county, the most populous part of which is dominated by contract practice. The result in another type of county might well be reversed. On the other hand, I suggest that my inquiry among Service members, when completed, may still further emphasize the verdict. All that can be claimed is that the figures provide prima facie evidence that the question of a State Medical Service should not only be a major issue for discussion by the Commission but that *it should receive priority over all other questions.* For it is impossible to plan rationally or build safely until the foundations on which the structure is to be erected have been decided upon and made secure.—I am, etc.,

Ashover, April 14. H. W. POOLER.

SIR,—I should like to make a few comments on Dr. Alan Marsh's alternative scheme (*Supplement*, April 19, p. 47). In the last few years the tendency to divide medicine into completely separate branches has been too freely indulged in, with the result that we now have overlapping in some cases and incoordination in others. To get the best we must have much closer bonds between general and consultant practice; they are not separate entities but component parts of medicine.

I cannot agree that a State service giving free treatment to those with incomes below £250 a year and reduced fees for those with under £500 a year is more likely to produce further schism in the profession than Dr. Marsh's suggestion of a glorified club practice. If complete equality is desired then I would suggest a free State service for all.

A fixed salary might destroy initiative and ambition, but in my scheme those with initiative and ambition are catered for, since without these qualities there would be no hope of attaining the higher posts in the Service. There would, however, be little opportunity for the "perfect bedside manner" or the fashionable society man who now reaps rich harvest "telling the tale" to rich dowagers—yes, even so to old men and maidens for that matter!

Stage 1 of Dr. Marsh's scheme is simply a glorified "club" practice, and as such is a retrograde step. We would revive local medical-aid societies and place ourselves under their dictatorial control. In Stage 2 the local medical officer of health takes a hand in our control. When Stage 3 is arrived at we start to form clinics at the local authorities' instigation; where the local authority is progressive, clinics would grow, but in non-progressive or depressed areas the clinics would remain castles in the air. Therefore, why not adopt a scheme in which the formation of first-class clinics in every area is the first step rather than one which provides them sometime or never? In Stage 4 both schemes run practically parallel, the only difference being that in my scheme this stage is arrived at by a shorter route.

Regarding finance, would it not be simpler for the State to be responsible for the upkeep of all the hospitals, for the salaries of the hospital staffs and the salaries of the medical staffs of the clinics, and for the local authorities to provide for the upkeep of the clinics? If any assistance to finance the scheme is required I would suggest those with incomes of over £500 a year paying for attention received rather than making a compulsory levy on the poorer classes. This would certainly make both classes feel more at ease under the new system.

The idea of increasing the value of practices is only further commercializing medicine, an evil already too great; after all medicine is an art, and art and commerce do not run well in double harness. In my scheme postgraduate study, holidays,

and pension are all adequately provided for, but Dr. Marsh leaves them all in their present neglected state. In any new scheme these are of paramount importance. Again, in his alternative scheme we should be under three masters—the local medical-aid society, the medical officer of health, and the Ministry of Health, but under my scheme we should have only one master—the central body, with at least 50% medical men in it, directly under the Ministry of Health—and it has been taught for nineteen hundred years that no man can serve two masters, so how would he succeed with three?

Finally, M.O.H.s, R.M.O.s, Colonial Medical Service M.O.s, and so on are all, to all intents and purposes, under State control, yet even so they manage to carry out their medical duties very efficiently and not fare too badly, so why should we dread the evil day so much? Our greatest danger is not State control but the bogy it conjures up in our imagination and the lack of unity in our ranks. We must hope that the Medical Planning Commission will succeed in formulating a scheme acceptable to profession, Government, and patient, and then that the profession will unite together when that scheme is put before Parliament so that we can show confidence in our scheme and by our unity ensure its adoption.—I am, etc.,

Wetherby, April 23. S. TERRY PYBUS, M.D.

SIR,—In the past faith has been an attribute of the Church, while the medical profession endeavoured to maintain an attitude of scientific detachment. Now, however, we seem to be showing a touching faith in the magic words "State service" and "clinic," and are closing our eyes to the examples already before us.

Your correspondents write of the wonderfully equipped "clinics" in which we shall work, the generous salaries we shall be paid, and the great benefits our patients will receive when we are a happy band of brothers working a State medical service under the benevolent and fatherly eye of the Ministry of Health. But do existing State services support this faith? The wonderful equipment of most infant welfare clinics appears to be a large bundle of "forms," one rather bent probe, and a bottle of hyd. c cretae tablets, while the clinic building is commonly a draughty church hall. As to salaries, this is an essentially "G.P." service, and the level of remuneration will serve as an index to the Governmental views on this subject.

The money value attached to consultant practice is shown by the E.M.S., where a man of established consultant status is paid £900 per annum for full-time service, while I have yet to hear any member of that service praise the equipment. This is wartime, when no member of a State Department ever thinks in units of less than £1,000,000. Can we expect an impoverished country after the war to do better?

It is true that on paper a State medical service can look very attractive, but I am afraid that in actual operation it would be very different. Let us not be mesmerized by words and so led into a situation worse than the present one.—I am, etc.,

Whetstone, N.20, April 26. A. C. ELKIN.

Public Health Appointments in Wartime

SIR,—The letters of "Midland M.O.H." and "S. L." (*Supplement*, April 5, p. 42, and April 26, p. 50), while stating two opposing points of view quite clearly, both fail to look at the problem concretely.

"Midland M.O.H." goes to the root of the matter when he says that a temporary appointment as medical officer of health will not attract the best men for the post, and at the present time it is more than ever essential that a medical officer of health should be both competent and energetic. Furthermore, if such a temporary appointment were filled by a thoroughly sound man, that man would probably hold an advantage over other candidates when the permanent appointment was made after the war, in which case the temporary nature of the first one would not have achieved the desired end. "S. L.," however, is quite right in his contention that members of the Services are as likely as civilian medical officers to be penalized by the age limit. This, however, will occur whether wartime appointments are permanent or not.

What appears to have been overlooked is that appointments as M.O.H., as distinct from posts as assistant M.O.H., are rarely given to men under 35 years of age, and few men of that age in the Public Health Service are likely to be called up for service with the Forces unless the war takes on a much more active form, in which case we shall be very much nearer to peace than we are at present.

The desirable policy would seem to be more or less as follows. Posts as assistant or deputy M.O.H., for which the younger men will apply, should be temporary. There will always be a good supply of vacancies of this kind in peacetime, so that at the close of the war the young man would still be able to find a place without undue difficulty. Posts as M.O.H. should be left to the local authorities' discretion, but no pressure should be brought to bear on them to make the appointments temporary. Last, and most important, the age limit of 45 should be abolished. It was imposed largely because of superannuation difficulties in the days when some authorities had such schemes and others had not, and it has been obsolete since superannuation schemes became compulsory. Some men are too old at 40, while others have their best years still to come at 50. Surely the upper age limit should, within reason, be as elastic as the lower.

Perhaps I might add, as disclaimer, that I am a comparatively young M.O.H. who will be none the worse for a period of "ripening" in my present post.—I am, etc.,

April 26. "NORTHERN M.O.H."

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Surgeon Commanders A. E. P. Cheeseman and G. E. D. Ellis have been placed on the Retired List with the rank of Surgeon Captain.

Surgeon Lieut.-Commander H. L. Belcher to be Surgeon Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieuts. T. D. Pilcher, O. G. Lloyd, B. S. Sher, G. Morrice, W. E. Willis, J. R. Oliver, T. J. A. Phillips, G. Sangster, K. M. Tomlinson, F. G. C. Walker, J. L. Elliott, T. R. Rutherford, J. B. Porteous, and C. H. Boyd to be Surgeon Lieutenants.

Probationary Temporary Surgeon Lieuts. P. N. Shutte, E. C. Coaker, T. B. FitzGerald, I. S. R. Bain, A. G. Cunningham, W. A. Burnet, E. J. Delorme, G. V. Blaine, H. P. Clark, C. J. Bintcliffe, W. T. K. Cody, G. Campbell, D. L. Carmichael, P. M. McAuley, W. S. Milne, W. P. Collingwood, J. H. Comloquoy, W. Cross, T. S. Eimerl, E. R. S. Grice, J. A. L. Leeming, A. C. C. Hughes, G. Garmany, A. W. McHaffie, R. Lawrie, N. B. Mundy, H. Jackson, R. S. G. Arnott, H. H. Johnson, H. E. D. Gale, W. Guthrie-Oman, R. T. Norman, W. J. Elliott, G. A. Hendry, C. W. D. Lewis, C. P. Madden, S. L. Hetherington, M. R. Ewing, R. L. Lawrie, J. R. Hart, L. D. De Launay, D. A. Daly, W. H. R. Cook, I. S. Jacklin, G. K. MacKenzie, S. S. F. Pooley, D. C. Galloway, A. G. Leakey, J. F. Buchan, J. W. Hall, G. A. Robinson, P. S. Hawkins, D. V. John, F. Hedley, A. C. Franks, F. C. Edington, J. D. D. Boswell, S. Meleck, B. Robinson, C. J. Martin, J. G. Pritchard, W. McL. Gillespie, R. O'Kane, J. B. Raffan, G. C. Glennie, J. MacRae, T. R. Simpson, R. M. M. Hunter, M. D. C. Hosford, J. M. G. Nixon, S. P. Cornell, G. W. Kennedy, P. D. Scott, L. V. Gimson, G. E. Loxton, G. R. C. Rayner, M. H. Small, E. T. Holman, P. D. MacLellan, A. S. S. Playfair, A. McKerlie, G. R. Thorpe, J. Price, A. B. Lennie, R. M. Bell, J. Jackson, A. S. B. McNeil, J. H. Kyle, O. H. Jones, C. A. Jackson, R. H. Elphinstone, I. H. Millar, J. M. Naish, L. H. James, A. J. O'Friel, C. E. Miller, E. P. J. Moran, W. R. Rochester, P. Walton, C. MacDonald, A. Watt, E. J. Wood, S. F. Taylor, W. P. Sweetnam, B. C. M. Reed, G. D. Taylor, J. F. Mullan, J. M. H. Mitchell, P. J. E. Palmer, R. C. Ponder, H. C. Pickering, C. Lewthwaite, L. D. Walker, N. L. Hulse, J. H. E. Summerhill, H. P. Dick, D. A. Thomson, F. J. Robertson, J. I. A. Jamieson, G. B. Stratton, D. W. Geidt, J. N. Hunt, E. E. T. Taylor, J. V. Rose, J. H. Graves, A. Young, G. H. Stuart, H. G. Easton, and R. Barrie to be Temporary Surgeon Lieutenants.

ARMY

Colonel (acting Major-General) P. S. Tomlinson, D.S.O., late R.A.M.C., to be Temporary Major-General.

ROYAL ARMY MEDICAL CORPS

The following Captains (Short Service Officers) have been appointed to permanent commissions: R. J. G. Morrison, J. A. G. Carmichael, A. T. Marrable, J. Shields, C. W. Maisey, T. M. W. D'Arcy, D. Wright, (War Substantive Major) J. W. Orr, and (Temporary Majors) K. H. Harper, M. F. Kelleher, and J. A. MacDougall.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Captains C. Shearer, G. Young, J. H. Ripley, H. R. G. Davies, and C. L. Taylor have relinquished their commissions on account of ill-health.

The names of the following Lieutenants are as now described and not as notified in the *Supplement* to the *London Gazette* dated February 18 and 28, and March 18, 1941: M. R. W. Spaeck, J. B. Hannah, N. C. Sharp, D. L. Bayley, T. V. H. Richards, B. McD. Johnson, J. H. Young, C. B. Ainscow, J. M. W. Wells, L. M. Kiernan.

The initials of G. S. A. Knowles are as now stated, and not as notified in a *Supplement* to the *London Gazette* dated November 6, 1939.

Lieuts. D. W. Warren, M. McLearie, and R. Nightingale have relinquished their commissions on account of ill-health.

To be Lieutenants: H. Goldsmith, J. H. Hale, D. A. R. Anderson, H. M. Bennett, G. Blair, W. J. Cameron, H. C. Carr, M. Cram, A. Farquhar, G. A. R. Gibson, J. K. Hampshire, A. T. Hunt, D. B. Jamie, W. H. L. La Frenais, L. Lloyd-Evans, H. MacLean, T. F. Main, S. S. Mair, Js. B. Malcolm, T. M. Pemberton, J. C. Renshaw, M. S. Richmond, G. D. Roworth, J. Scobbie, W. Stoddart, J. Sutton, J. E. Taylor, W. P. Wallace, R. Wright, F. H. MacB. Dummer, C. J. S. Flood, J. H. France, W. D. Giffen, M. Good, E. Keidan, R. T. Kiddie, H. McKeown, J. M. McLean, D. M. Milne, J. S. Montgomerie, H. M. Weaver, E. G. W. Clarke, J. C. Goligher, M. Price, H. L. Koebner, R. L. Mackay, P. R. Wilson, J. S. Hunter, C. W. M. Whitty, T. G. McCarthy, J. Burton, V. Guyer, J. K. Hewat, C. E. Perry, O. A. Savage, H. MacN. Symons, W. R. Stephen, T. G. Anderson, J. K. Houston, P. H. Beamish, P. J. England, I. C. Fraser, E. Geal, E. E. Swaby, J. McMichael, M. A. G. Ward, G. A. F. Quinnell, C. de V. Shortt, E. MacLaine, E. G. Muir, P. G. F. Harvey, R. Anderson, A. J. Bain, J. Bunting, W. V. A. Erskine, H. Fuld, S. R. Goshng, J. Harders, C. Kenton, P. Kinnear, J. W. Leslie, G. I. W. Usk, R. J. A. Macdonald, W. Macfarlane, W. H. Mackenzie, D. P. Macmillan, E. H. Moore, R. Posner, J. Scorgie, M. S. Segall, S. R. N. Smith, J. M. Terris, S. M. Thompson, I. D. Willatt, G. T. T. Wishart, M. Elias, J. S. Foster, H. Goodwin, B. E. P. McCullough, L. Spira, J. O. D. Williams, D. Wyllie, G. F. H. Drayson, D. A. D. Montgomery, R. A. Coughlan, D. Feldman, J. Gordon, J. J. Spira, T. M. A. Lewis, R. L. Hartley, A. S. Thenuwara, S. B. Karani, W. Aird, J. R. Allan, J. S. Kennedy, A. H. Lafone, J. Morrison, C. N. Robinson, B. Sandler, N. W. Snell, J. B. Stafford, J. Blum, G. G. Dickie, R. A. Beaver, W. Darby, H. W. John, J. Patton, R. G. Tiechurst, T. Crawford, H. W. Perkins, J. W. S. Macfie, R. W. Mellor, R. Thornley, W. M. Dickson, I. B. Morris, J. B. Young, P. W. Green, A. L. H. Rackham, W. H. R. Lumsden, C. T. Jones, E. R. Cullinan, J. Taylor, W. C. Blackham, H. C. Edwards, A. C. Byles, D. McD. I. Hartmat, R. W. Brookfield, E. Alderson, H. B. Follit, J. G. T. Lunn, J. S. McGillivray, N. W. Hammer, S. Barclay, J. C. Carson, C. Cotterill, J. F. K. Grieve, H. Kennedy, K. I. W. Kleinberg, H. S. Laird, J. McGlade, I. McLennan, J. J. Murray, A. McI. Runcie, W. M. H. Shaw, M. J. MacKenzie, I. Calvert-Wilson, H. F. Devlin, J. B. Farquhar, C. G. Johnson, I. R. Jones, A. M. Loughran, R. G. Paley, J. Urquhart, J. D. Wilson.

Lieut. D. F. Suttie, from Camerons (Emergency Commission), to be Lieutenant.

Dr. E. K. P. Harris (Medical Officer with the relative rank of Lieutenant) has relinquished her appointment on account of ill-health.

The name of Margery Feachem is as now described and not as notified in a *Supplement* to the *London Gazette* dated March 7, 1941.

To be Medical Officers with the relative rank of Lieutenant: Celia M. M. Calvert-Evans, Emily E. Cass, Phyllis M. Edwards, Alfreda W. Krichruff, Hyacth M. Warwick, Sheila Carmichael, Hilda M. S. Davidson, Jean Mather, Jessie M. Hudson, Iris Copeman, Alice M. Watt, Mary M. Thomson, Julia M. Brown, Eileen McC. Gibson, Mary Rennie.

THE ARMY DENTAL CORPS

Captain W. G. S. Wilson, Southern Rhodesia Medical Corps, to be Lieutenant.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

The notification in the *London Gazette* dated February 28, 1941, concerning C. C. Edwards should read Squadron Leader instead of Flying Officer.

To be Honorary Flight Lieutenants: J. G. Lynch, R. J. Sims, J. Tobson-Smith.

To be Flight Lieutenants for the duration of hostilities: W. Leslie, B. J. Bickford, M. O. J. Gibson.

The notification in the *London Gazette* dated February 28, 1941, concerning E. H. Hudson should read Flight Lieutenant instead of Flying Officer.

Flying Officers O. H. Sennett, D. Stevenson, J. Brown, W. Goulstone, E. I. Davis, J. O'Brien, A. L. Collins, R. F. H. McElligott, E. G. Patchett, A. E. R. Chalmers, C. Barton, G. E. B. Scott, M. C. T. Reilly, R. Piper, J. E. T. Strickland, H. Whittle, A. B. Rowlands, G. Macnaughton, J. C. Hill, H. B. Sutton, G. Shneerson, A. J. Beddie, P. S. Meyrick, B. W. Sanderson, and N. A. F. Young have been promoted to the war substantive rank of Flight Lieutenant.

Miss Winifred H. Redmond has been promoted to the relative rank of Flight Lieutenant.

To be Flying Officers for the duration of hostilities: W. C. D. Bewick, C. P. Williams, J. K. Swanston, W. P. Soutter, J. J. O'Dwyer, R. L. Markham, J. R. C. Williams, H. Brewster, J. M. Crawford, W. H. G. Elliott, J. G. Fee, J. Lillie, I. M. Macgregor, J. James, A. E. Ward, W. G. Zorab, J. S. H. Scott, F. A. Thompson, E. R. T. Crabb, S. E. White, T. J. Conran, S. Goide, M. Crowley, A. A. Macgibbon, E. J. G. Murray, I. B. Good, R. H. Francis, E. G. Fox, J. Guthrie, T. H. Redfern, C. M. Dickins, T. L. Barbour, F. J. R. Stoneham, P. E. Percival, R. J. L. Ferris, I. W. H. R. Cran, R. E. J. Clarke, J. Burdon-Cooper, A. J. S. B. Tawse, R. W. S. Marshall, J. E. McKnight, W. E. Greenwood, L. H. McGrath, C. W. Hall, B. G. Gretton-Watson, A. Buchan, T. E. Griffiths, C. F. H. Wiessner, W. Kirk, E. F. Mason, A. Webb-Jones, A. C. Bingold, L. J. Stoll, P. A. Dawes, A. D. Macdonald, E. W. Jones, H. L. B. Girvan, M. T. Gallagher, E. S. Frazer, J. G. Smith, J. Tolland, A. L. Walby, R. B. Walker, R. A. Mitchell, M. L. Mason, W. W. Cashmore, D. M. Douglas, S. R. Warren, G. B. Schofield, A. A. Simpson, J. L. Sinnette, D. E. Williams.

The notification in the *London Gazette* dated March 28, 1941, concerning Flying Officer A. F. Baldwyn should have appeared under the heading Royal Air Force instead of the Royal Air Force Volunteer Reserve.

Postgraduate News

The Fellowship of Medicine announces the following courses in preparation for the next M.R.C.P. examination: chest diseases at Brompton Hospital, Mondays and Thursdays at 5 p.m., May 26 to June 19; nervous diseases at West End Hospital for Nervous Diseases, Tuesdays and Fridays at 3.30 p.m., May 27 to June 20.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Mon.*, Course of lectures on War Surgery of the Extremities commences. *Daily*, 10 a.m. to 4 p.m., Medical Clinics, Surgical Clinics and Operations, Obstetrical and Gynaecological Clinics and Operations. *Daily*, 1.30 p.m., Post-mortem Demonstrations. *Tues.*, 11 a.m., Paediatric Clinic, Dr. R. Lightwood. *Wed.*, 11.30 a.m., Clinico-pathological Conference (Medical). *Thurs.*, 2 p.m., Dermatological Clinic, Dr. R. T. Brain; 2 p.m., Radiological Demonstration, Dr. Duncan White. *Fri.*, 12 noon, Clinico-pathological Conference (Surgical); 2 p.m., Clinico-pathological Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr. V. B. Green-Armytage.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, *Thurs.*, 4.30 p.m. Mr. Bruce Dick: Surgical Aspects of Diseases of the Chest.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Therapeutics and Pharmacology.—Tues., 3 p.m. Annual general meeting. W. E. Dixon Memorial Lecture by Prof. J. A. Gunn: Future of Pharmacology.

Special Meeting of Fellows.—Tues., 4.30 p.m. To consider alteration in By-law I, 2. Nomination of officers and council for 1941–2.

General Meeting of Fellows.—Tues., 5 p.m. Ballot for election to Fellowship.

Section of Surgery.—At Horton Hospital, Epsom, Wed., 2.45 p.m. Annual general meeting. 3 p.m., Clinical demonstration.

Section of Dermatology.—Thurs., 4.30 p.m. Annual general meeting. Short papers.

Section of Neurology.—Thurs., 5 p.m. Papers by Dr. W. Russell Brain and Dr. G. Weddell.

Section of Obstetrics and Gynaecology.—Fri., 4.30 p.m. Annual general meeting. Case reports.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Cruden (Aberdeenshire); Royton (Lancashire); Darlington (Durham). Applications to the Chief Inspector of Factories, Queen Anne's Chambers, 28, Broadway, S.W.1, by May 20.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

HUNTER.—At the Quarry Nursing Home, Shrewsbury, to Joyce (*née* Peat), wife of Roger B. Hunter, M.B., Bridge, Canterbury, a daughter.

MARRIAGE

POVEY—ROBERTSON.—At Leeds, on April 17, 1941, John E. Povey, B.Sc.Lond., Flight Lieutenant, R.A.F.V.R., to Margaret F. Robertson, M.B., Ch.B., D.R.C.O.G.

DEATH

SANJANA.—On March 22, 1941, Dr. Darabshaw Farduonji Sanjana, Sanjan House, Lawrence Street, Kelty, Fifeshire.

TRAUMATIC EPILEPSY AFTER GUNSHOT WOUNDS OF THE HEAD

BY

P. B. ASCROFT, M.S., F.R.C.S.

Assistant Surgeon, Middlesex Hospital; Major, R.A.M.C., Surgical Specialist at a Military Hospital (Head Injuries)

The object of this paper is to summarize the results of an inquiry into the fate of men who sustained gunshot wounds of the head in the war of 1914-18, with special reference to the development of epilepsy. Through the kindness of the Director-General of Medical Services, Ministry of Pensions, 540 case notes have been examined. These were taken from the files of the group known as "four-year cases"; that is to say, all the patients survived long enough to be re-examined with a view to final award of pension four years after they were first "boarded" for head injury by the Ministry of Pensions. The material thus does not include those who died from the results of head injury within the first few years, before their pension reached the stage of final award. It is possible also that certain cases of minor injury not severe enough to receive provisional award of pension may have escaped the survey; but a man bearing on his head a visible scar or a hole in his skull as a result of war service seldom failed to appeal and to obtain an award of 20% or more. With these reservations the group may be accepted as a fair sample of gunshot wounds of the head involving bone, and a somewhat selected sample of the severer scalp wounds.

Information Available

Relating to each case are four groups of documents. (1) There are the strictly medical papers—the field medical card, and corresponding medical cards completed at the base hospital in France or elsewhere and at the general hospital in the United Kingdom, and one or more Army Forms I 1237. (2) The medical board papers. Boards were held first, as a rule, when the patient was discharged from hospital, then at intervals of six months, and later of one or two years, until the final board, usually in the period of 1922-5. When a final award had not been granted because the case did not appear to be in a final and stationary condition, or when later appeals were lodged by the man, further medical board reports are available, perhaps as late as 1930, 1935, or more recently. (3) Long after the war many pensioners were admitted to Ministry of Pensions hospitals for observation, and hospital reports are often available. (4) In addition there are the man's non-medical military documents, a collection of papers relating to the non-medical side of pension arrangements, including any letters from the man himself or from his relatives or friends. Should the pensioner at any time come into conflict with the civil power a record of the crime and sentence is to be found.

The most serious omissions from the medical notes are the family history and the previous history of the patient.

Selection of Cases

Of the 540 case records examined 317 have been abstracted, the rest being discarded. Rejections were made solely on account of incomplete notes, especially an incomplete operation note. All cases having adequate notes were accepted, no matter how trivial the injury. No injuries from causes other than gunshot wounds are included in the present series. Wounds of the cerebellum have been excluded.

Incidence of Epilepsy

Of these 317 cases, 107 (34%) had fits. Every patient whose notes record one or more fits is included, yet this figure is perhaps a little low. It has not always been easy to determine from the records whether or not a patient has had fits, but it is reasonably safe to assume the fits to be genuine when they are accepted as an attributable disability by medical boards. The majority of men complaining of fits were admitted to Ministry of Pensions hospitals for observation, often for long periods.

It is possible that an occasional patient was falsely accepted as epileptic. On the other hand, it is probable that a number of cases of genuine epilepsy without full-fledged convulsions were missed. In the records examined there is little or no reference to automatic states and to less outspoken forms of epilepsy. In some cases not regarded by medical boards as genuine epilepsy the description of attacks is nevertheless convincing, and these cases are included in the 107. But they are few, and it is therefore fair to conclude that the figure of 34% is at least not an over-estimate.

The following case reports illustrate the varieties of epilepsy encountered and indicate the sort of data on which the present survey is based.

Major Epilepsy without Obvious Focal Onset

Case No. 108.—Wounded on October 4, 1918, at the age of 17. While advancing the patient was struck by a shell splinter in the left temporal region and knocked down. He stated that he was able to get up immediately and walk to the dressing station, where he lost consciousness, and did not "come to" till three weeks later in England. On arrival at the base hospital he was found to be dysphasic and to have weakness of the right arm, leg, and face. Radiographs revealed a depressed fracture and two metallic fragments one centimetre within the skull, near the Sylvian point. At operation two days after the injury fragments of depressed bone were removed and there was found to be "some loss of brain substance"; the foreign bodies were not seen. Six days after the injury he had a convulsion with loss of consciousness. Occasional slight fits occurred during the rest of his prolonged stay in hospital (the wound did not heal for seven months). He remained hemiplegic, though his leg regained enough power to enable him to walk, and his memory and intelligence were said to be good. The fits grew more frequent; in 1919 they took place twice a month, and in 1921 two operations were performed. The first, in February, revealed the hole in the skull filled with fibrous tissue. Beneath it lay a "large subdural

cyst," which was swabbed out with iodine and filled with a graft of fascia lata and muscle. The fits continued, but were fewer. In June of the same year the wound was reopened, a fruitless search made for the foreign bodies, and a second graft applied. For a time he had up to six fits a week, but the following year only one a fortnight. Improvement, however, was brief. In 1925 fits took him so often that he was unable to go out alone; in 1926 he had two a day, and in 1927 four. In 1930, fifteen years after the injury, fits were so frequent that he required constant attendance.

Case No. 124.—Wounded on July 6, 1915, at the age of 19. This man was struck in the posterior part of the left frontal region near the vertex, and was said to have been unconscious for seven days. He was trephined next day; bone fragments, hair, and dirt were removed from the surface of the brain, the wound drained, and the edges drawn together. Healing was complete in twenty-five days and no focal signs are recorded. Six to nine days later he had two attacks of loss of consciousness, preceded by trembling of both arms. He recovered and was able to carry on his pre-war work of farm labourer, and a year later was engaged in felling timber. In 1920, however, he had another fit, with generalized convulsions in which he bit his tongue and wet himself. For more than a year there was no further attack. In 1922 fits began again, and by 1924 took place every month. When last examined in 1926, eleven years after the injury, he was having fits every week.

Epilepsy with Focal Onset

Out of a total of 107 cases of epilepsy, 33 (31%) are recorded as having a focal onset. This group consists mostly of fits starting with jerking or some abnormal sensation in a limb. In addition there are two cases of occipital injury in which the fits began with flashes of light; three of occipital injury in which the fits began with or were characterized by dimness of vision and blindness; and one of injury to the left temporal lobe having minor fits in which speech was lost. No instances of uncinate fits are recorded. It is possible, therefore, that the focal features of attacks have been overlooked in some cases.

Case No. 175.—This man was wounded at Gallipoli on May 24, 1915, at the age of 31. A bullet glanced off the side of his head, causing a depressed fracture over the lower part of the left Rolandic area. He was unable to speak, and his right arm and leg were powerless and insensitive. Trephining was performed aboard a hospital ship, but the condition of the dura is not stated. Within a year he was able to walk well, but there was still severe sensory loss in his right hand, and speech was hesitant. Fourteen months after the wound he began to have fits. Before a fit he "only saw half a thing," and his right hand went numb; occasionally he lost consciousness and wet himself. At first fits were infrequent; by 1920 they occurred monthly, and in 1924 every week. He was, however, able to retain his job as a gateman. He died of heart failure due to mitral disease in March, 1937.

Case No. 268.—Wounded on July 27, 1917, at the age of 29. A bullet pierced this soldier's steel helmet and ploughed a furrow in his scalp from front to back, an inch to the right of the middle line. The wound was excised four days later, and the bone was seen to be grooved but not broken. The wound was septic, and he lay five months in hospital. The first fit took place a month after he left hospital. It began with pain in the left arm, and consciousness was lost. Similar attacks followed at intervals of about three months. In 1923, seven years after the injury, they ceased. For ten years he had no more. But in 1933 attacks occurred every week for a time, yet ceased once more four months before his last medical board examination (held the same year), at which his pension remained at 50%. There is no record of his ever having had focal signs.

Case No. 127.—Nine months previously this patient had sustained a slight scalp wound, but had remained on duty. On August 20, 1917, at the age of 21, he was struck on the right side of the head by shrapnel balls. One penetrated just in front of the ear, lodged in the bone, and drove a shower of bone fragments into the parietal lobe. On admission to hospital he was semiconscious and disorientated. His head and eyes were deviated to the right, but he could be induced to look to the left, this movement being accompanied by nystagmus. There was left hemiplegia, complete in the arm and almost complete in the leg. Sensory tests were unreliable. He was operated on about twelve hours after injury by Harvey Cushing (1918, Case 36).* The wounds were excised and sutured. The shrapnel ball in the petrous bone was removed, together with many fragments of petrous bone and pieces of helmet lining. In the parietal region the bone and the shrapnel ball in it were removed *en bloc*. From the brain itself fragments of bone, much clot, and disorganized brain were removed to a depth of 5 cm. The wounds healed by first intention. A month later his left leg was nearly normal, and within four months of injury his left hand had a fairly good grasp and was still improving. He was deaf in the right ear. In January, 1918, after he was evacuated from France, an aluminium plate was inserted. A week later he had an attack of twitching of the left side of the face and left arm. He remained fully conscious, the fit was slight, and there was no further attack for a year. Thereafter other attacks followed with increasing frequency, and in 1924, seven years after the wound, they took place two or three times a month. Consciousness was never lost, but whereas twitching had been confined to his arm and face, in later years it spread to his foot.

Petit Mal

Case No. 100.—Wounded on June 24, 1917, at the age of 42. A shell splinter glanced off this man's skull in the left fronto-parietal region, causing an extensive scalp wound but not injuring the bone. His right arm and leg were found to be weak. Power soon returned, and he was able to serve at home till demobilization. He complained that his right hand was still numb, and he was found to have astereognosis, impairment of postural sense in the right hand and right foot, and a right extensor plantar response. Nevertheless he was able for a time to take up his old employment as a blacksmith's striker. When last examined in 1931, fourteen years after the injury, he reported that he had been obliged to relinquish that particular work as he had suffered for some four years from attacks "in which he lost himself for a few minutes."

Case No. 148.—This man sustained a severe penetrating wound of the left lower parieto-occipital region, through which the brain fungated. Four months later he began to have attacks which he described as follows: "I feel something inside my head which feels altogether strange. Something goes like a flash through my head and I feel unsteady. At times when I wish to speak my speech goes twisted."

Depth of Wounds and Fits

The incidence of fits in relation to the depth of wound is shown in Table I.

TABLE I.—*Relation between Epilepsy and Depth of Wound, Foreign Bodies, etc.*

Group	Site	No. of Cases	No. with Fits	% with Fits
1 ..	Scalp	66	16	24
2 ..	Fractured skull; dura intact	104	24	23
3 ..	Metal in brain	42	16	38
4 ..	Metal removed from brain	30	16	53
5 ..	Dura torn; brain injury; bone fragments removed or *in situ* (exclusive of Groups 3 and 4)	57	26	46
1 & 2	Dura intact; all cases	170	40	23
3, 4, 5	Dura penetrated; all cases	129	58	45

Fits are twice as frequent when the dura is penetrated. Nearly half (45%) of such cases are affected.

Metallic Foreign Bodies and Fits

It is remarkable to find that patients who retain fragments of metal in the brain are less liable to fits than those from whose brain metal has been removed (Table I). There are several possible explanations. Surgical removal of the missile may greatly increase the damage to the

* Dr. Cushing's case report describes the head wounds as being on the left side, but the Ministry of Pensions records leave no doubt that they were on the right side.

brain or, under conditions often obtaining in war, increase the sepsis. Another and more acceptable explanation is that most of these retained missiles are small splinters, often less than a centimetre in diameter and often with a small entrance wound. When a man is struck by a large lump of metal it kills him if it penetrates far; if it remains near the surface, though it can be readily removed, it causes much destruction. Consequently, of men surviving penetrating splinter wound of the head, those in whom the metal is retained may well have less cerebral damage and therefore less liability to fits.

The surmise that the cases in which metal was removed from the brain often have more serious brain damage than those in which metal remains *in situ* is supported by the fact that 12 of the 30 from whom metal was removed developed brain fungus, whereas only 3 of the 40 from whom the metal was not removed had fungus. Furthermore, included in the "metal removed" group are 13 through-and-through wounds, and these are usually severe injuries.

The important fact that emerges is that in penetrating wounds the mere presence of a small piece of metal in the brain does not increase the risk of epilepsy.

Other Late Complications, and Deaths

It may be added that so far as the late course is concerned the presence of metal in the brain does not seem to affect the outlook in any way. In fact, apart from epilepsy, late complications are astonishingly rare in the whole series, even in the severest wounds. It is to be remembered that the present study affords no information concerning fatal complications arising within the first four or five years after injury, nor are the records complete enough to give information concerning minor degrees of mental deterioration. No cases in the series were still receiving active treatment, so that the material gives no information about patients requiring permanent institutional treatment on account of psychosis.

Up to the end of 1940 14 patients (4.4%) have died. In only one case (No. 126) can death be attributed with certainty to the injury; in two others (Nos. 79 and 265) there is a probable direct connexion.

Case No. 126.—Wounded on November 1, 1916, at the age of 22. A shell splinter entered the brain in the left Rolandic region, causing a right hemiparesis. The patient was not operated on till the fifth day, when a cerebral abscess was drained. Considerable recovery of power took place, and he was able to work as an auxiliary postman till 1930, when minor attacks of epilepsy began. Major fits developed a year later, ending in a fatal status epilepticus in September, 1934, eighteen years after the wound. Necropsy revealed a "cyst" on the surface of the brain, but there was no trace of abscess or other septic complication.

Case No. 79.—Wounded on September 4, 1917, at the age of 20. There was a small wound of entrance in the left temporal region, and the patient was dysphasic and weak in the right arm. Operation next day revealed much pulped brain, which was removed, along with several fragments of bone. The wound healed in twenty days, and the dysphasia and weakness improved rapidly. *X*-ray examination showed a piece of metal, 1 by 0.5 by 0.4 cm. in diameter, 1 cm. to the left of the middle line and 1.5 cm. above the sella turcica. Fits began in the following year and grew more frequent. In 1933 glycosuria was discovered, and the patient died in diabetic coma in July, 1937, twenty years after his wound.

Case No. 265.—This man was wounded on February 27, 1917, at the age of 23. A scalp wound was sustained in the right parietal region. At operation three days later the wound was excised and the bone was found to be intact. Major fits began in June, 1922, causing him to lose his job as stage-door keeper. By 1929 fits were frequent and prolonged. He died in October, 1938, of "acute bronchitis and chronic epilepsy," twenty-one years after being wounded.

The cause of death in the remaining 11 cases is recorded as: heart disease (5) malignant disease (2), perforated gastric ulcer (1), bronchopneumonia (1), phthisis (1), influenza (1).

In-driven Bone Fragments and Fits

With regard to the significance of in-driven bone fragments and the risk of fits it has not been possible to extract satisfactory data. Judging by our experience at the Military Hospital for Head Injuries and by the reports of members of the Society of British Neurological Surgeons, bone fragments are driven into the brain in almost all penetrating injuries. Good radiographs are needed to detect them, and it is clear from the samples of old *x*-ray plates included in the Ministry of Pensions files that reports of negative radiological findings are unreliable. Many operation notes state that in-driven bone fragments were removed, but there is no guarantee that all of them were. Pieces of buried bone may be overlooked at operation, even with the help of modern radiography; with poor radiographs, or none, fragments will often be left.

Non-penetrating Wounds and Fits

It is surprising to find the incidence of fits in scalp wounds as high as 24% (Table I)—no less, actually, than in wounds fracturing the skull and often depressing bone. The fact that this series of scalp wounds is to some extent selected may account for the high incidence of fits. Many a scalp wound will in itself cause no disability, and the patient may only appeal for a pension should epilepsy follow. But there are other points to be considered. Scalp wounds due to projectiles are by no means the same as those seen in civil practice and due to a fall on the pavement or a blow with a brick. The outward effect on the scalp in the shape of a more or less linear cut is the same, that on the brain beneath quite different. The brick imparts its momentum to a wide area of the skull and brain, or, rather, to the whole head, and usually stuns the victim. The bullet or splinter pierces the scalp and strikes the skull, a very small area of which absorbs its momentum, and often the patient is not concussed. Should the bone be broken it is remarkable how localized the fracture is—often no larger than the missile—showing how concentrated and focal is the blow. It is the exception to see widely radiating cracks which indicate diffusion of force. There is also ample clinical evidence to show that a concentrated impact can injure the underlying brain without breaking the bone, for in these cases focal signs are common (Jefferson, 1919; Cairns, 1941). In this series of 170 cases in which the dura was intact 51 (30%) had focal signs of cerebral damage. Of 104 cases in which there is a note on the state of consciousness 25 are known not to have been unconscious, yet 7 of these developed fits, and in 4 the skull as well as the dura was intact.

Though one cannot readily accept the high figure of 24% as the true incidence of epilepsy in wounds no deeper than the scalp, it is clear that scalp wounds due to projectiles are more likely to be accompanied by local damage to the brain, and therefore epilepsy, than scalp wounds seen in civil practice.

Sepsis and the Incidence of Fits

An important aspect of the problem of traumatic epilepsy is the incidence of fits in relation to sepsis. This is shown in Table II.

TABLE II.—*Relation between Epilepsy and Wound Sepsis*

	No. of Cases	No. with Fits	% of Fits
Wound healed in 15 days	59	13	22
,, 15–30 days ..	53	17	32
,, unhealed after 60 days ..	53	24	45

In this series fits developed twice as often in cases of severe and prolonged sepsis as in those healing by first intention. To obtain a truer estimate of the influence of sepsis the figures must be analysed further. Since both fits and sepsis are commonest when the wounds are deep and severe, the causal relation between sepsis and fits suggested by these figures might be fictitious. In Table III, therefore, the cases are grouped according to the integrity of the dura mater, and we see that the same relation holds for scalp wounds as for penetrating wounds—namely, that fits are commoner when wounds are septic.

TABLE III.—*Relation between Epilepsy and Wound Sepsis*

		% with Fits
Dura intact	Healed in 15 days	12
	,, ,, 15-60 days	30
	Unhealed in 60 days	32
Dura penetrated	Healed in 15 days	36
	,, ,, 15-60 days	50
	Unhealed in 60 days	57

Site of Wound in Relation to Incidence of Epilepsy

Too much reliance should not be placed on these figures (Table IV) nor on those previously published. It is often stated that fits are commonest in parietal lesions, but it is not always clear if "parietal" refers to the bone or to the lobe. There is also a tendency, seen in the records of this series, to describe as parietal any wound not frankly frontal, temporal, or occipital. Furthermore, the damage to the brain giving rise to the fits is not necessarily directly beneath the site of bone injury. For what they are worth the figures (Table IV) show that wounds in and about the Rolandic area are most often followed by fits, and polar wounds least often.

TABLE IV.—*Site of Wound in Relation to Incidence of Epilepsy*

Site		No. of Cases	No. with Fits	% with Fits	% with Fits, All Cases; assuming Equal Proportion of Penetrating and Non-penetrating Wounds
Frontal*	Dura intact	49	11	22	26.5
	Dura penetrated	35	11	31	
Rolandic	Dura intact	26	10	38.5	46.0
	Dura penetrated	28	15	54	
Parietal*	Dura intact	52	13	25	38.5
	Dura penetrated	23	12	52	
Temporal*	Dura intact	19	5	26	42.5
	Dura penetrated	17	10	59	
Occipital*	Dura intact	22	3	14	27.5
	Dura penetrated	22	9	41	

* Refers to the lobe, not the bone.

As a rough approximation it may be said that the further a wound lies from those portions of the cortex where sensori-motor function is predominantly represented, the less chance is there of subsequent epilepsy. Though it is legitimate to conclude that lesions near the sensori-motor cortex more often lead to epilepsy than do those at the poles of the cerebral hemisphere, the figures make it clear that the influence of the site of the wound on the liability to epilepsy is not great.

Concussion and the Incidence of Fits

The importance of local brain damage as the essential factor causing epilepsy in gunshot wounds of the head is emphasized in another way. In 104 cases the effect of the wound on consciousness is recorded. In 55 the dura was intact. In these the incidence of fits was practically as high in those remaining conscious as in those concussed (Table V).

TABLE V.—*Concussion and Incidence of Epilepsy*

	No. of Cases with Dura Intact	No. with Fits	% with Fits
Not unconscious	19	5	26
Unconscious	36	10	18

Time of Onset of Fits

The first fit may take place within a few hours of injury or may be delayed as long as twenty years. In this series information of the time of onset of epilepsy is available in 84 of the 107 cases, and is given in Table VI. When fits began while the patient was still in hospital the precise date of onset was usually available; but when fits began after discharge from hospital, which usually took place about three months after injury, the exact time of onset is often not recorded. The accompanying chart is

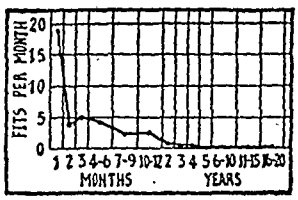

Chart showing monthly incidence of onset of epilepsy.

a graphical expression of Table VI, and shows the monthly incidence of onset of fits. For the reasons just stated the monthly incidence after the first three months is expressed on the chart as an average of three-monthly periods for

TABLE VI.—*Time of Onset of First Fit*

	Months						Years					
	1	2	3	4-6	7-9	10-12	2	3	4	5	6-10	11-15	16-20
No. of new cases of epilepsy	19	4	5	13	7	8	10	4	4	1	6	1	2

the remainder of the year, and as an average of each period of twelve months from the second to fifth year.

It will be observed that the rate of onset of fits during the first month exceeds by more than four times that of any subsequent month. After the initial fall it remains stationary till the sixth month, then falls again, till at the end of the second year a very low figure is reached. During the next three years the rate of onset declines further, and after four years is barely above the base-line. Only about one patient in twenty-seven developed epilepsy between the fifth and twentieth years.

Course of the Epilepsy

Information concerning the course of the epilepsy is available in 96 of the 107 cases.* In 30 of these, fits ceased some years before the final examination. The cases may thus be separated into two groups: those with persistent epilepsy and those with temporary epilepsy. By *persistent epilepsy* is meant that in which attacks were known to continue when the patient was last examined. By *temporary epilepsy* is meant that which is known to have ceased some years before the final award of pension.

The cases of temporary epilepsy fall into two distinct categories. In 11 of the 19 patients who had fits within the first days after injury (Table VI) fits ceased within the first fortnight, not to return (Category I). It is to be noted that there were no cases in which fits began in the

* These 96 cases comprise the 84 cases of which the time of onset is known and an additional 12 cases in which the later history but not the time of onset was available.

third and fourth weeks. This prevalence of epilepsy within the first fortnight after injury is doubtless connected with the presence of recent cortical damage due to haemorrhage or infection, and it accords with the not uncommon experience of fits in the first days after operations upon the brain, or after spontaneous subarachnoid haemorrhage. As in these conditions, fits occurring soon after injury are of little prognostic significance for the occurrence of late epilepsy.

There are a further 19 cases in which fits eventually ceased, but after a much longer interval (Category II). In 3 of these, fits began within the first two weeks and continued for two and a half, three, and four years respectively. The other 16 cases of temporary epilepsy began three months to two years after the wound, to disappear one to four years later. The average interval between the last fit recorded and the final examination is five years, the shortest two, and the longest eleven years.

Examples of prolonged temporary fits are afforded by the following cases.

Case No. 82.—Wounded on March 24, 1918, at the age of 24, by a shell splinter in the right lower anterior parietal region. Four days later at a base hospital the patient was trephined, and many fragments of bone were removed from the brain. Seven days after the wound he is described as being very dull but without paralysis. A week later a large fungus developed, and with it complete hemiplegia. He was doubly incontinent and remained critically ill for many weeks. Nine weeks after injury much of the fungus was cut away, and after a further three months the wound eventually healed. Very little power or sensation returned in the paralysed limbs. About a year after the wound he began to have fits every month, in which he lost consciousness and was incontinent. When last examined in 1934, sixteen years after the wound, he had had no fits for over ten years.

Case No. 210.—This man was wounded on June 23, 1916, at the age of 29, by trench-mortar fire. He was struck in the right frontal region. He was not unconscious, and the wound was trivial. Radiographs revealed neither foreign body nor fracture. No operation was performed, and he was back on duty at the end of the week. The next day he had an attack of twitching of the left hand, spreading to the whole of the left side, and he was sent to England. While under observation in hospital he had two more Jacksonian attacks. After leaving hospital in August he returned to duty and was sent to Salonika in April, 1917. He remained well until January, 1918, eighteen months after his wound, when the fits recurred and he had as many as fourteen in one day. On January 22 a trephine opening was made over the arm area of the motor cortex, some distance posterior to the site of the wound. Nothing abnormal was found. Fits continued on and off till June, then grew less frequent and ceased. At the time of his last attendance before the medical board he had had no fits for five years; his sole complaint was of giddiness on stooping at his work as a farm labourer, and he was awarded a pension of 30%, mostly on the basis of the trephine hole in his skull. He had never appealed for more pension.

In the 19 cases categorized as prolonged temporary epilepsy there may be some that have had unrecorded attacks since the last examination, but in view of the fact that some of the patients have been free from fits for as long as eleven years it is not possible to explain away the impermanence of the epilepsy on this basis. What part may have been played by sedative drugs cannot be determined from the information available. In two of the cases the delayed onset of septic complications in the wound may have contributed to the presence of the temporary epilepsy.

In all the cases in which fits began more than two years after receipt of the wound the epilepsy was of a persistent character, attacks continuing up to the time of the last examination (Table VII).

TABLE VII.—*Time of Onset of First Fit in Relation to the Course*

	Weeks			Months					Years	
	1	2	3 & 4	2	3	4-6	7-9	10-12	2	3-20
Temporary	12	2	0	0	2	3	0	1	3	0
Persistent..	3	2	0	4	3	10	7	7	7	13

Epilepsy is more likely to be of a persistent character in those cases in which the dura was penetrated by the wound (Table VIII).

TABLE VIII.—*Relation of Integrity of Dura to Temporary and Persistent Epilepsy*

	Temporary Fits	Persistent Fits
Dura intact	41% (7 of 16 ceased in first 2 weeks)	59%
Dura penetrated	26% (3 of 14 ceased in first 2 weeks)	74%

When the focal signs clear up the prospect of the epilepsy also clearing up is enhanced (Table IX).

TABLE IX.—*Influence of Recovery of Focal Signs on the Course of the Epilepsy*

	Temporary Fits	Persistent Fits
Transient focal signs	37%	12%
Permanent focal signs	26%	46%

These late follow-up results thus show that in about one-third of the patients having fits after gunshot wound of the head epilepsy may be of a more or less transient character. The earlier the fits begin the less likely are they to become persistent. In the first week after injury, if we may judge from this series, the risk of a man having fits is about 5% (15 of 317 cases), but the risk of the fits becoming persistent is only 1 in 5. Fits starting in the second week stand an equal chance of being temporary or of becoming persistent. As the weeks pass the odds against the fits being of a temporary character rapidly increase. From the sixth month to the end of the second year the risk of developing epilepsy is about 10%, but the odds favour the epilepsy becoming persistent as 5 to 1. If the onset of fits is delayed beyond two years the epilepsy will be persistent.*

Summary

The Ministry of Pensions records of 317 cases of gunshot wound of the head of the 1914-18 war have been examined with regard to the occurrence of epilepsy. The series represents a fair sample of head injuries that were severe enough to receive an award of pension yet not so severe as to cause death in the first four years after injury. The period of follow-up varies from about seven to twenty years. Blunt injuries and wounds of the cerebellum have been excluded.

Of the 317 cases 107 (34%) developed epilepsy.

Up to the end of 1940, 14 (4.4%) of the patients had died. One, and probably two others, died of complications of the brain wound, the remaining 11 of intercurrent conditions.

In cases in which the dura had been penetrated fits were twice as frequent (45%) as in the scalp and skull wounds in which the dura was intact (23%).

Scalp wounds due to missiles are more likely to be followed by epilepsy than are scalp wounds due to blunt injury.

There was no evidence that removal of metallic foreign bodies from the brain diminished the liability to epilepsy.

* In this connexion it is necessary to add that the series gives no information about the effect of operative excision of brain scars upon the course of the epilepsy.

Prolonged wound sepsis, as indicated by delayed healing, favours the subsequent onset of epilepsy both in cases in which the dura has been penetrated and in those in which the integrity of the dura has been preserved.

Epilepsy is more common after wounds affecting the sensori-motor cortex than after wounds of the polar regions of the cerebral hemisphere.

The presence or absence of concussion (immediate unconsciousness) after gunshot wound does not influence the subsequent liability to epilepsy.

The first fit may occur within a few hours after injury or may be delayed at least as long as twenty years. Epilepsy begins more often in the first two weeks, and thereafter the liability to develop epilepsy progressively diminishes.

In 30 of the 96 cases in which the course of the epilepsy is known fits ceased some years before the patient was last examined. This subsidence of epilepsy occurred most often in cases in which fits began in the first fortnight after injury, less frequently when fits began within the first two years, and never when the first fit occurred more than two years after the injury.

It is a pleasure to record my thanks to Dr. Prideaux of the Ministry of Pensions for his kindness in arranging for examination of the case records, and for much help in their interpretation. I am especially indebted to Colonel Hugh Cairns for his constant advice and great help in revision of this paper.

RECENT MORTALITY FROM BRONCHITIS IN LONDON

BY

RALPH M. F. PICKEN, M.B., Ch.B., B.Sc., D.P.H.

Mansel Talbot Professor of Preventive Medicine, University of Wales

Until the Registrar-General's Annual Statistical Review appears there is no information as to the main causes of death throughout the whole country in any period of time. Such records were last published for the year 1938, but figures are given for the administrative county of London under "short list" headings in the weekly returns, which have continued to be published since the outbreak of war. It is possible, therefore, to compare the experience of the years 1939 and 1940 with that of previous years for this area. The fifty-two weeks covered by the weekly returns do not coincide exactly with calendar years, but the slight error in taking the sum of the figures contained in them as a year's experience is unimportant. When this is done the very great increase in the number of deaths classed in 1940 as being due to bronchitis immediately hits the eye. Stocks (1940) has shown that the greatest single cause contributing to a general excess of deaths at ages over 45 in London between January 7 and February 17, 1940, was bronchitis. During this short period deaths from all causes exceeded the number expected on the basis of the same weeks in 1939 by 1,900, or nearly 33%; those from bronchitis were 800 (106%) in excess. With all the information of the Registrar-General's office at his disposal he was in a position to eliminate the several fallacies of comparison which will be discussed later, and the great increase in mortality from bronchitis he reveals must be accepted as real. The period of time was, however, very short, and a lesser but substantial excess in the deaths from some other causes, such as influenza, pneumonia, and heart diseases, which he demonstrated then would probably not have been sustained if the figures for a longer period had been examined by the same methods. He drew attention to the fact that these rises coincided with the exceptionally cold spell of weather in January and February. The point is important, for any change of mortality which is contemporaneous with the war is apt to be regarded as one of its results. The experience of the whole year therefore deserves as careful examination as possible.

Statistical Discontinuities

At the outset we are faced with certain difficulties. We know that the population of the administrative county of London has been falling steadily for some time. Between 1921 and 1931 it fell from 4,484,523 to 4,396,821—i.e., by nearly 2%. The mid-year estimate for 1938 was 4,062,800, representing a rapid decline of more than 8% during the seven years since 1931. So long as comparisons of death rates, not merely of deaths, are made this fall does not matter. In 1939 the population was estimated at 4,013,400, but this figure was adjusted for death-rate purposes to 3,780,700 in order to allow for evacuation movements and the exclusion from the death returns of non-civilian deaths since the outbreak of war (L.C.C. Report, 1939). Estimates for 1940 have not yet been published and are beyond the competence of anyone without access to official records, but it would not be unreasonable to suppose that the deaths in 1940 occurred among a population not exceeding, on the average, three and a half millions. If this is so we should expect a reduction in the number of deaths from all causes, as compared with the average of the previous ten years, of at least 16%, in the absence of factors inhibiting such a decline. Further, since the outbreak of war deaths have been assigned to the place of occurrence and not to residence. This may seriously affect comparability. In the circumstances of 1940 it would probably reduce the recorded deaths from natural causes in London. A still more serious interference with continuity is the change made by the Registrar-General in the method of classifying causes of death since the beginning of 1940. Whereas formerly the selection of one cause for the purpose of classification from more than one stated in a death certificate was made according to arbitrary rules, it is now determined so far as is possible by the order of preference indicated by the certifying practitioner. It is easy to see that this change (which was bound to come sooner or later) gravely affects comparison with the statistics of previous years. The adoption at the same time of the 1938 revision of the International List of Causes of Death is less likely to affect the comparability of figures relating to those causes with which this paper is concerned. It is, at least, clear that, for the present, the large number of deaths from bronchitis in 1940 has to be examined without any attempt to express it as a death rate, and that we must make sure that it is not an artificial result of changes in statistical procedure.

In a normal year nearly 90% of the deaths classed as due to bronchitis in London occur at ages over 45. It is therefore a cause mainly affecting those who have passed middle age, and it rapidly increases in old age. In 1939 92% were over 45, and in 1940 the proportion rose to 95%. The reasons for this rise may be disregarded for our present purpose. The point is that we are considering for 1940 a condition affecting the usual elderly age group of the population. It kills especially those whose cardio-vascular and renal systems, as well as the respiratory, are degenerating. When death occurs it must often be hard

for the practitioner to decide whether the most important cause is respiratory or cardiovascular or even, on occasions, renal. He may mention one or more of these systems in his certificate. In the past the Registrar-General of England and Wales has placed bronchitis very low in the order of preference. He chose a definite cardiovascular against any respiratory cause except lobar pneumonia (and, of course, influenza) if both were stated on one certificate, but a comparison recently made by the United States Government of the classification of the same group of certified deaths by the statistical departments of several countries showed that this policy was not so much favoured in some of them (Bureau of Census, Washington: Vital Statistics). Within our own country the preferences of medical practitioners differ from those shown by the Registrar-General in the past, and they also change with advancing knowledge, or, it may be, with medical fashion. Fashion, of course, has not suddenly changed in 1940. From year to year the Registrar-General has shown how bronchitis and old age have declined as assigned causes of death over 70 years of age, their place having been taken largely by heart diseases through increasing use of the terms "myocarditis" and "myocardial degeneration." A death ascribed to "bronchitis and myocardial degeneration" has hitherto been classed under the latter heading, whereas it is probable that if practitioners had been restricted to one single cause many would have preferred "bronchitis." The growth in the proportion of certificates showing such multiple causes no doubt accounts for much of the recorded fall in death from bronchitis and the rise of heart disease. The effect of following the practitioner's choice instead of the statistician's is revealed in the Annual Statistical Review for 1937 (Registrar-General's Review, 1937). It is shown for the records of 1936 and 1937 that a change from the arbitrary rules to acceptance of the certifier's choice would have reduced the deaths throughout England and Wales classed to heart diseases by about 28,000, or 22%, and increased bronchitis by 15,000 to 16,000, or 86 to 89%. Here, then, is a very great discrepancy, especially in the recorded mortality of bronchitis, which must vitiate all comparisons between 1940 and previous years until the figures are published by the Registrar-General in comparable form. On the other hand, nephritis would have been increased by only 1% under the new system.

Comparison with Previous Years

It is necessary to keep these facts in mind when examining the London statistics for 1940. For reasons already given it is not practicable to compare the death rates with those of previous years; but the actual deaths classified to certain causes are shown here in tabular form, their relation to those of previous periods being brought out in the second half of the accompanying table. In addition to the average for the ten years 1930 to 1939 (inclusive), the year 1929 has been shown separately because influenza was unusually prevalent then, a fact which has a bearing on the number of deaths classed to bronchitis.

For obvious reasons deaths from violence other than suicide are not included in the deaths from all causes for each period stated in the tabulation. The total number of deaths from all other causes has fallen by less than 9% as compared with 1930-9. As already indicated a greater fall might have been expected from the reduction of population, although old folks, who contribute heavily to the deaths, probably have not left London in such a high proportion as younger people. On the other hand, the deaths in 1940 were 27% lower than in 1929, a fact which, taken in conjunction with the very great difference in influenza certifications in these two years, confirms the common observation that no serious epidemic of this disease occurred in 1940. All respiratory causes taken together (including influenza) have risen, but to nothing like the level of 1929. In this group, however, bronchitis alone accounted for even more deaths than in 1929, the deaths from this cause far exceeding those from pneumonia for the first time in any of the years under consideration, and being nearly two and a half times the average of the previous ten years. The fall in pneumonia deaths was a little greater than might have been expected, and when this is viewed along with a considerable increase in the deaths classed to "other respiratory causes" as well as to bronchitis, it may be suspected that there has been an artificial inflation in these latter categories at the expense of pneumonia. The Registrar-General's inquiry indicated that the new system might lead to a very slight increase of recorded pneumonia, and the absence of epidemic influenza may have been in itself sufficient to account for the relatively low figure for pneumonia, but the influence of sulphonamide therapy has also to be kept in mind.

When we turn to the cardiovascular group a marked discrepancy is observed between the behaviour of deaths from cerebral vascular lesions (cerebral haemorrhage, apoplexy, etc.) and other cardiovascular causes. The sharp rise in the former is possibly statistical rather than real, although there was no indication from the Registrar-General's inquiry that this might be expected. The stress of these times may be a partial explanation. It is better, however, to take the two groups of causes together. There is less of a drop (2%) in the deaths from all cardiovascular causes than might have been expected from the fall of the population and the change of method in classification. The smallness of the decline may be due to the same reason as the rise in bronchitis. It is probable that, if the old

* Figures for 1939 and 1940 are the sum of the weekly returns, which do not coincide exactly with calendar years.

system of selection for classification had persisted, still more deaths would have appeared in the circulatory group and fewer as bronchitis, but that both would have shown an increase. Nephritis has declined substantially as compared with the average of the previous ten years; but this is part of a steady and quite rapid process over the years, and the figure for 1940 actually exceeded that for 1939 in spite of the fall of population. There is thus no evidence that bronchitis has borrowed materially from nephritis. This, like the other degenerative causes, may really have increased in 1940. The same comment applies to "old age,"* which has been figuring less and less in London statistics, but which nevertheless accounted for 226 more deaths in 1940 than in 1939. For purposes of classification it is still ignored as a cause if it is associated with any definite disease. The only other large category which showed a substantial decline was "other specified causes" (from 1,731 in 1939 to 1,229 in 1940, a difference of 502), but it is doubtful whether many of these would find their way to bronchitis by a change in the system of classification.

Discussion

The general conclusion from these considerations is that a large part of the increase of the deaths ascribed to bronchitis in the weekly returns for London in 1940 was fictitious, but that part of it was genuine. This part could not be attributed to influenza. It was associated with an increase, or less than the expected decrease, of certain other causes of death common among the elderly. Was it a result of war conditions?

The mortality from bronchitis, like other respiratory causes, and indeed like nearly all causes of death, has a definite seasonal distribution. Between 1921 and 1925 the average maximum for the whole country was in February and the minimum in August (Registrar-General's Review, 1925). In the chart shown here the average weekly number

London (Administrative County): average weekly recorded number of deaths over 45 years of age from bronchitis, in four-week periods, from November, 1933, to March, 1941.

of deaths over 45 years of age from bronchitis in London is given in periods of four weeks from November, 1933, to March, 1941. The comparison before and after the beginning of 1940 is valid, of course, only for seasonal occurrence and not in relation to its magnitude. It will be seen that the peak most often occurred in the first four weeks. In this respect 1940 conformed to type. In so far as there was a real increase in mortality from bronchitis, most of it was in the beginning of the year, before the people began to resort to shelters. The most notable feature of this season was the rigour of the weather. Unfortunately, meteorological records have not yet been published, but the weather in December, January, and February is known to have been exceptionally severe. Russell (1924, 1926) has drawn attention to the dominating effect of atmospheric temperature on respiratory mortality even in the absence of fog. The bitter weather at the beginning of 1940 was in itself probably enough to account for any increase in deaths from bronchitis and other causes among old people. If towards the end of the year shelter-life and exposure had any effect it was apparently not great, when the artificiality of much of the apparent increase is kept in mind. In 1941 the cold spell, severe but rather less so than in 1940, came later in the year, and the peak of bronchitis deaths was delayed till the second four weeks, when it was quite pronounced. It is, of course, possible that in both these seasons the effect of the black-out exaggerated the influence of the ill ventilation which always accompanies cold weather and favours respiratory infection; but the conclusion seems reasonable that the real part of the increase in mortality from bronchitis and other causes among old folks was mainly attributable to exceptional weather conditions and not to circumstances arising from war.

* Figures of old age are not included in the table because this heading did not appear in the short list till 1931.

Summary

There was a great increase of recorded mortality from bronchitis in London in 1940, affecting the elderly.

A large part of it was an artificial result of a change in the system of selecting one cause for classification from more than one cause stated in death certificates.

In so far as it was real it occurred mainly at the beginning of the year, as usual.

It was not due to an epidemic of influenza.

It occurred, probably along with an excess over the expected number of deaths of old people from other causes, during one of the most severe spells of weather this country has experienced, and should not be regarded as having been due to war conditions.

The Royal New Zealand Society for the Health of Women and Children, which was founded by the late Sir Truby King, gives in its latest annual report some of the vital statistics of the Dominion. The birth rate in 1939 (excluding Maoris) was 18.73 per 1,000, the highest recorded since 1930. The maternal mortality rate, excluding septic abortion, was 2.95, and the infantile mortality rate 31.14 per 1,000 births, almost the lowest ever recorded. The death rate during the first month of life was 21.8, an improvement on the figure for recent years. The names and addresses of all infants who died during the year were obtained from the Registrar, and the Plunket nurses employed by the society investigated every case. An inquiry has also been made into the extent and duration of breast-feeding in New Zealand and the causes of early weaning, the outstanding one being failure of the milk supply of the mother. During the year further efforts have been made by the Plunket nurses to extend their pre-school work, and a ready response has been made by the parents. The society has six infants' hospitals in various parts of New Zealand, and the 138 Plunket nurses in its service saw 22,000 new cases during the most recent year, and paid 170,000 visits to homes.

THE BACTERIOSTATIC EFFECT OF DISINFECTANTS IN HUMAN SERUM AND CITRATED PLASMA

BY

MARGARET E. MacKAY

(From the M.R.C. Serum Drying Unit, Cambridge)

Although human serum is not a good medium for bacterial growth, bacteria will remain viable in it, and certain organisms will grow in it even at temperatures as low as 0° C. This is also true for reconstituted dried serum, so that bacterial infection is a potential danger in the use of reconstituted dried serum as a transfusion fluid—particularly since during the process of solution serum may become contaminated either through careless handling or by the use of non-sterile water in dissolving the serum. It is improbable that serum contaminated in this way would be a danger to the patient if it were used immediately after reconstitution, but if it were allowed to stand under bad conditions of temperature bacterial growth would take place. Therefore an attempt has been made to find a disinfectant which could be added to the serum before drying, or to the dissolving fluid, in a concentration that would be bacteriostatic and yet within the limits of toxicity even when large volumes of serum were transfused. At a later stage an experiment on citrated plasma was included.

During the course of the experiments it was found that *Staph. aureus*, *Micrococcus tetragenus*, and an enterococcus grew readily in serum from an original inoculum of 20 organisms per c.cm. Under similar conditions no growth of anthrax, streptococci of the "Oakley" strain, *Bact. aertrycke*, *Bact. shigae*, or *Bact. coli* could be demonstrated, while *B. subtilis* grew in serum after a preliminary delay during which the presence of living organisms could not be proved. The work was therefore carried out using *Staph. aureus*, *M. tetragenus*, *B. subtilis*, and an enterococcus as contaminating organisms in the serum. These organisms might reasonably be expected to be found as contaminants in stored serum or plasma, and members of the *subtilis-megatherium* group, micrococci, and pseudomonas have been isolated from serum received at this laboratory for drying.

A disinfectant to be used for the preservation of stored serum should be soluble enough to be added in a concentration that will not dilute the serum unduly. It must not react with serum proteins to alter their physical characteristics, and must be active as a bacteriostatic within the limits of toxicity of the drug even when large volumes of fluid are to be used. During the course of the experiments eight disinfectants were tried. These included four mercurials—merthiolate, metaphen, phenyl mercuric nitrate, and phenyl mercuric acetate; also proflavine, sulphanilamide, thymol, and *p*-chlor-*m*-cresol.

Effective Range of the Disinfectants

The effective range of concentration of each disinfectant was first determined. To 0.9 c.cm. of serum or reconstituted dried serum was added 0.1 c.cm. of a suitable concentration of disinfectant, depending on its solubility in water; from this mixture a series of falling dilutions was made in serum. In the case of metaphen four doubled dilutions were made, but with the other disinfectants four or five decimal dilutions were used, and of each dilution three tubes were set up. To each tube 0.02 c.cm. of a saline suspension containing 2,000, 200, or 20 organisms was added, and a control tube containing 1 c.cm. of serum without disinfectant was inoculated with each suspension. The tubes were incubated at 37° C., and growth was tested by making a stroke inoculation on an agar plate at intervals. Saline suspensions of bacteria were prepared by washing the growth from a twenty-four-hour agar slope culture and diluting with sterile saline until the suspension contained 1,000 million organisms per c.cm. measured by opacity. Dilutions of 1/1,000, 1/10,000, and 1/100,000 were made from this, and one drop from a fifty-drop pipette was used as an inoculum so that each drop contained 2,000, 200, or 20 organisms. The test organisms used in this series were *Staph. aureus* and *B. subtilis*.

Results of a typical experiment are shown in Table I, which indicates that 1/125,000 is the minimal concentration of phenyl

inoculum has been neglected, since no gross differences could be demonstrated by varying the size of inoculum between 20 organisms and 2,000 organisms per c.cm. As is shown in Table II, the lowest concentration of disinfectant in serum which will inhibit growth has been determined.

Testing for Viable Organisms

In a second series of experiments an attempt has been made to see whether viable organisms were still present despite the absence of growth in the serum. So viable counts were

carried out on reconstituted dried serum inoculated with a suitable organism and incubated at 37° C. with the highest dilution of disinfectant which in the experiments described in the previous paragraph had been shown to inhibit bacterial growth. In this series the inoculum was always 20 organisms per c.cm

Method.—To 9 c.cm. of reconstituted dried serum made up to normal concentration 1 c.cm. of a suitable dilution of disinfectant was added so that the final disinfectant-serum mixture contained a dilution of disinfectant which had been shown to inhibit growth (Table II). Each tube was inoculated with 0.2 c.cm. of a saline suspension of bacteria, prepared as before, the final concentration of bacteria being 20 organisms per c.cm Control tubes containing 10 c.cm. of serum without disinfectant were inoculated with 0.2 c.cm. of the same suspension; the tubes were incubated at 37° C. Similar tubes were set up using citrated plasma as the growth medium for the bacteria. Viable counts were carried out by Miles's (Aitken, Barling, and Miles, 1936) " surface viable " technique after variable periods of time, but if growth in the serum-disinfectant mixture could be demonstrated at an early stage further counts were omitted. Three decimal dilutions were made in sterile saline, and a drop from a 50-drop pipette was allowed to fall on each of three marked places on an over-dried agar plate; each count is the average of three such drop areas containing a suitable number of colonies. Similar counts were carried out on control sera. As a routine the sera were inoculated with *Staph. aureus, B. subtilis,* and an enterococcus. Drop areas of *Staph. aureus* and enterococcus containing up to 60 colonies could be counted accurately, but the *subtilis* colonies were very large, and from 8 to 20 only could be counted. The results with this organism are therefore less accurate. The method of testing for viable organisms by plating from a ten-times dilution of the serum-disinfectant mixture was based on the assumption that by diluting the serum-disinfectant mixture ten times the concentration of disinfectant becomes low enough to allow inhibited but still viable organisms in the original disinfectant mixture to grow in the lower concentration. Thus serum containing merthiolate 1/100,000 inhibited the growth of *Staph. aureus,* but, on diluting, these organisms were able to grow. The dilution to 1/1,000 was made in order to get drop areas which would contain a countable number of colonies.

Results.—A summary of results is presented in Table III. In the case of merthiolate and phenyl mercuric nitrate (1/100,000) growth of bacteria could be demonstrated on diluting the serum-disinfectant mixture, so that fresh experiments were set up. Merthiolate was tried in a dilution of 1/10,000 because that dilution was already commonly used in the preservation of citrated plasma and was found to be effective in this concentration. Phenyl mercuric nitrate, except when the serum was contaminated with enterococcus, was effective in a concentration of 1/50,000.

Effects of Use of Disinfectants

Effect of Drying Disinfectant with Serum.—Sulphanilamide, metaphen, phenyl mecuric nitrate, and proflavine were added to the serum before drying, and the bacteriostatic power was estimated after reconstitution. So far as could be seen, freezing at − 20° C. and drying had no effect either on the bacteriostatic power of the disinfectant or on the solubility of the serum. Bacterial counts were also made on serum which had been made up to four times the normal concentration on reconstituting. Again no difference in bacteriostatic power of the disinfectant could be detected.

Effect on Pseudomonas pyocyanea.—In a bottle of reconstituted dried serum containing phenyl mercuric nitrate 1/10,000, from which a sample of serum had been taken with a chemically clean pipette for an osmotic pressure estimation, *Ps. pyocyanea* was found to be growing profusely. A loopful of this serum was added to serum containing 1/10,000 proflavine, and a loopful of a saline suspension of this organism was added to dried serum containing merthiolate, metaphen.

TABLE III.—*Growth in the Presence of Disinfectant*

and phenyl mercuric acetate, so that the final concentration was 1/10,000. Growth of the organism could be demonstrated in three days at room temperature. Apparently none of these disinfectants will control the growth of pseudomonas.

Effect on Moulds.—The inhibitory effect of proflavine and phenyl mercuric nitrate on moulds was tried in one experiment. A series of half dilutions of disinfectants was made in reconstituted dried serum from 1/10,000 to 1/160,000, and these were inoculated with a small amount of the vegetative form of an air-borne mould growing in serum broth. At room temperature growth took place in all dilutions of the serum containing proflavine, but was inhibited by 1/80,000 phenyl mercuric nitrate. There was no apparent difference in the tubes containing proflavine and in the controls.

Effect of Sulphanilamide in Serum and Blood.—Because of our inability to repeat the results of Novak (1939) one experiment was carried out on the lines suggested by Novak and Hunwicke (1940). Into twelve tubes 40 c.cm. of sterile citrated human blood was measured. Four were inoculated with a saline suspension of *B. subtilis*, four with *M. tetragenus*, and four more with *Ps. pyocyanea*. The suspensions were so adjusted that the blood contained 20 organisms per c.cm. Two tubes of each group were kept as a control, and to the others sulphanilamide was added, the final concentration being 1/5,000. One of each of the tubes containing organism and sulphanilamide, and its appropriate control, were held at room temperature, and the second set at 4° C. The blood was tested for bacterial growth after four days and seventeen days by smearing a loopful on the surface of an agar plate. After thirty days' incubation poured plates were made, those of the blood held at 4° C. with 1 c.cm., those held at room temperature with 0.1 c.cm. After four days at room temperature evidence of growth was obtained in the control tube containing *B. subtilis*, and after seventeen days growth in the tube containing *M. tetragenus* and *Ps. pyocyanea* was demonstrated. The plates poured after thirty days showed profuse growth of the bacteria in all tubes, and there was no obvious difference between those which contained sulphanilamide and the controls. With the exception of the control tube containing *Ps. pyocyanea* there was no growth in any of the tubes held at 4° C. After fifty-four days these tubes were incubated at 37° C. for three days and plates poured, using 1 c.cm. of blood as an inoculum. Profuse growth was observed in the plates from the control tubes, but there was no growth in any tube which contained sulphanilamide. Except that no growth of the controls could be shown at 4° C., these results corroborate those reported by Novak and Hunwicke.

Conclusions

As had been expected from Fildes's (1940) work the bacteriostatic power of mercurial disinfectants was considerably less in serum than in other media. Birkhaug (1930) has reported that metaphen in serum broth will destroy *Staph. aureus* in a dilution of 1/120,000. In serum a dilution of 1/80,000 allowed definite bacterial growth, and 1/40,000 proved only bacteriostatic—that is, bacteria would grow when the serum was diluted.

The efficacy of the individual disinfectants tried in these experiments appeared to depend entirely on the contaminating organism. *Metaphen* in a dilution of 1/10,000 inhibited the growth for six days of *Staph. aureus* and *B. subtilis* in serum, but enterococcus and *Ps. pyocyanea* grew in this concentration. Metaphen is soluble in dilute alkali (*p*H 9) in a concentration of 1/500, and does not affect the physical nature of the serum (Birkhaug, 1934; Hirschfelder and Wright, 1930). Bernstine (1929) has reported the intravenous injection of 10 mg. of metaphen without toxic effects. It will be observed, however, that the transfusion of 1 litre of serum would involve the injection of 100 mg. of the disinfectant.

Merthiolate had an activity of the same order as metaphen, except that no growth of enterococcus could be demonstrated in six days with a dilution of 1/10,000. This dilution did not prevent the growth of *Ps. pyocyanea*. Merthiolate is relatively non-toxic, and does not affect serum proteins (Powell and Jamieson, 1931).

Phenyl mercuric nitrate was effective against *Staph. aureus* and *B. subtilis* in a dilution of 1/50,000, but this dilution did not prevent the growth of enterococcus after six days, and 1/10,000 had no effect on the growth of *Ps. pyocyanea*. The growth of mould was inhibited by 1/80,000. The *p*H of the medium did not affect the bacteriostatic powers of this disinfectant. Drying the serum in the presence of 1/10,000 phenyl mercuric nitrate had no effect on the osmotic pressure after reconstitution (Adair, personal communication). Phenyl mercuric nitrate is reported to be less toxic than metaphen, which contains the same amount of mercury (Birkhaug, 1930). The chief objection to the use of this disinfectant is its insolubility in water, a saturated solution containing only 0.79 gramme per litre.

Phenyl mercuric acetate was tried because it was more soluble and would appear to be effective in a concentration of 1/100,000; but this concentration precipitated serum proteins.

Proflavine 1/100,000 prevented growth of *Staph. aureus* and *B. subtilis* for six days and enterococcus for three days. A concentration of 1/10,000 did not prevent the growth of moulds or of *Ps. pyocyanea*. Eggerth's (1926) observations on the effect of the hydrogen-ion concentration could not be repeated; proflavine was as active in plasma at a *p*H of 6.0 as in serum at a *p*H of 8.4.

Sulphanilamide proved ineffective in serum and plasma in inhibiting bacterial growth. Novak (1939) and Hunwicke (1940) have reported that 1/5,000 sulphanilamide would prevent the growth of organisms in stored citrated blood for twenty-one days. In serum from an inoculum of 20 organisms per c.cm. there is no growth of *Staph. aureus, B subtilis, M. tetragenus*, or enterococci for twenty-four hours after incubation at 37° C.; but after this time growth of all these organisms was observed and the degree of inhibition depended on the organisms. *Enterococci and micrococci grew readily* at 37° C., the count of micrococci increasing from 4,150 bacteria per c.cm. in two days to 53,000,000 in seven days. Control counts on serum without sulphanilamide during the same period showed a count of 466,500,000 in two days and 54,500,000 in seven days. At 4° C. serum which had become contaminated with *M. tetragenus* and had an initial count of 200 organisms per c.cm., after three days in the presence of sulphanilamide contained 5,500 organisms per c.cm., and after six days contained 45,000 bacteria per c.cm. Counts on serum without sulphanilamide increased from 4,350 bacteria per c.cm. in three days to 45,000 in six days. This serum had been held for some months at −20° C. Growth of *Staph. aureus* was inhibited to some extent by sulphanilamide. In serum inoculated with 20 organisms per c.cm. and incubated at 37° C. the count after two days was 24,000,000 organisms per c.cm. and 91,500,000 after seven days. Serum containing 1/5,000 sulphanilamide under similar conditions had a bacterial count of 9,000 bacteria per c.cm. in two days and 2,900,000 in seven days. It would appear, therefore, that sulphanilamide will inhibit the growth of organisms in serum for twenty-four hours but cannot be relied on for any longer period.

The results obtained when using citrated whole blood as a growth medium for the bacteria substantiate those previously described by Novak in human blood and by Hunwicke in horse and guinea-pig blood.

Thymol and *P-chlor-m-cresol* were shown to be quite unsuitable as serum preservatives: both allowed the growth of organisms in a dilution of 1/2,000, and caused the precipitation of serum protein

Discussion

From these experiments it would appear that disinfectants can have only a limited value in controlling the bacterial growth in stored serum. Of those tried the most effective was proflavine. In a concentration of 1/100,000 it prevented the growth of *Staph. aureus* and *B. subtilis* for six days and of enterococcus for three days. A dilution of 1/10,000 had no effect on *Ps. pyocyanea* or mould. From recent work (Albert *et al.*, 1938) it is evident that much higher concentrations are equally ineffective against pseudomonas. Higher concentrations of any of these disinfectants would not be practicable because of the danger of toxic reactions.

Bottles of serum sent by the Emergency Blood Supply Depots of the London region for drying in this laboratory

have been tested for sterility as they were received, and the results of these tests have been reported back to the depots. Some of the bottles have been found to be contaminated, and the number has steadily decreased as the depots have gained experience in the separation of the serum. As in no case was there any evidence of gross infection, and as the bottles are held at 4° C., at which temperature bacterial growth is slight, the infected bottles were pooled with the sterile ones during filtration. The majority of the contaminants were spore-bearing aerobes of the *subtilis* type, and Gram-positive cocci—either micrococci or sarcinae; pseudomonas was also isolated from serum and from stored citrated plasma. The necessity for filtration is evident, and from experimental results it is also evident that, although the contaminants of the *subtilis* type would be susceptible to the action of disinfectant, the Gram-positive cocci and pseudomonas would be resistant to its action, and the value of adding disinfectant to serum is doubtful.

While it is obvious that the correct procedure is to maintain conditions of absolute sterility during both the preparation and the solution of dried serum, and that the reconstituted serum should be used immediately, it is possible that in wartime reconstitution might take place under difficult conditions and it might not be possible to use the serum immediately. In such circumstances results would indicate that proflavine 1/100,000 and phenyl mercuric nitrate 1/50,000 would prevent bacterial growth for three days.

Summary

The effect of various disinfectants in controlling the growth of bacteria in serum, dried and reconstituted serum, and citrate plasma has been studied.

Growth of *B. subtilis* and *Staph. aureus* was prevented for six days by merthiolate 1/10,000, metaphen 1/10,000, phenyl mercuric nitrate 1/50,000, and proflavine 1/100,000. Growth occurred in sulphanilamide 1/5,000 after twenty-four hours.

Enterococcus was inhibited for three days by phenyl mercuric acetate 1/100,000, proflavine 1/100,000, and merthiolate 1/10,000. Growth in three days could be demonstrated in the presence of metaphen 1/10,000, phenyl mercuric nitrate 1/50,000, and sulphanilamide 1/5,000.

Ps. pyocyanea was not inhibited by any of these disinfectants.

Thymol and *p*-chlor-*m*-cresol were ineffective as bacteriostatics; and these and phenyl mercuric acetate precipitated proteins in serum.

Freezing at −20° C. and drying in serum did not affect the bacteriostatic power of metaphen, sulphanilamide, proflavine, and phenyl mercuric nitrate; nor did the presence of the disinfectants affect the solubility of the dried serum.

Moulds were inhibited by 1/50,000 phenyl mercuric nitrate but not by 1/10,000 proflavine.

Sulphanilamide will prevent the growth of *B. subtilis*, *M. tetragenus*, and pseudomonas in whole blood for thirty days at 4° C. but not at 22° C.

It is stated that no fewer than 65 countries of the world have sent delegates from their student youth to study in Germany.

LACTOSE FOR PREVENTION OF ODOUR IN THE CLOSED-CAST TREATMENT OF COMPOUND FRACTURES

BY

ALLAN D. WALLIS, M.D.

AND

MARGARET J. DILWORTH, B.S.

(From the Germantown Dispensary and Hospital, Philadelphia, U.S.A.)

The increasing use of the closed-cast method of treating compound fractures, particularly under wartime conditions, induces us to propose a means of preventing the foul odour that is one of its principal disadvantages. Our procedure, of which a more detailed account will be published elsewhere, has been devised in connexion with the treatment of osteomyelitis by the Winnett Orr technique. The application of that method to compound fractures has been well described by Trueta (1939).

Protein-sparing Effect of Carbohydrate

Briefly stated, it is our hypothesis that the foul odour which develops in these casts is the result of putrefaction, defined by Rettger (1928) as "anaerobic decomposition of protein with the formation of foul-smelling products characteristic of cadaveric decomposition." Autolysis of devitalized tissue probably helps to initiate this proteolysis by providing preliminary breakdown products which are more readily attacked by micro-organisms than are native tissue proteins. It seems likely that anaerobic bacteria play an important part in putrefaction. Trueta (1939) has noted the presence of anaerobes in the wounds under consideration. Whether these organisms arrive through the blood stream or by accidental implantation remains to be determined. On the basis of these assumptions, by implanting a sugar in the wound one may take advantage of the fact that most bacteria will attack carbohydrate in preference to protein when both are simultaneously available. As Kendall *et al.* (1913) have expressed it: "Fermentation takes precedence over putrefaction." It is when bacteria are utilizing protein for fuel rather than for merely structural requirements that foul products are formed. This principle is commonly referred to as the "protein-sparing effect of carbohydrate."

In selecting a sugar for use in wounds lactose was chosen instead of glucose because, since its molecule is larger (Kendall and others, 1913), a solution of it isotonic with the blood contains more sugar, and (Kendall, 1923) loss by absorption from the wound should be less. Since the first stage in the fermentation of lactose is the production of galactose and glucose, the latter becomes available for the relatively few organisms which cannot utilize lactose.

Method of Using Lactose

For clinical use we have arbitrarily chosen a 12% solution. Lactose of *U.S.P.* grade is dissolved in distilled water and autoclaved in quantities of about 50 c.cm. Sterile gauze dressings which have been dipped in this solution are placed in the wound instead of the usual vaselined gauze packs. A covering of dry gauze is employed to keep the sugar from contact with the plaster lest crumbling occur. In débridement the solution should be made and autoclaved within two hours of the time the water is distilled, as a precaution against the presence of spores. At subsequent re-dressings this precaution is unnecessary, since the granulation tissue is an adequate barrier against toxins (White, 1931).

We have employed this method in Winnett Orr casts for periods up to four weeks without the development of

a definite odour of putrefaction. For longer periods it is possible that larger amounts of sugar may be needed. These could be provided by increasing the concentration of the solution or by adding crystalline lactose to the dressings. With the use of lactose both the amount of exudate and the tendency to excoriation of the surrounding skin appear to be diminished, probably because bacterial production of proteolytic enzymes is decreased in the presence of utilizable carbohydrate (Kendall, 1923). The usual healing process does not seem to be impaired by the addition of sugar. The dressings do not become adherent to the wound as is sometimes the case with vaselined gauze. Since *B. pyocyaneus* has little or no ability to utilize sugar this method does not affect its odour, which, however, is not nearly so offensive and penetrating as that of true putrefaction.

It is to be hoped that the use of lactose will prove as satisfactory in compound fractures as it has in osteomyelitis.

ACUTE DILATATION OF THE STOMACH

BY

MAURICE LEE, F.R.C.S.

AND

EDGAR SOMERVILLE, M.B., B.Ch.

It is our intention, as the result of an unusual case of acute dilatation of the stomach, to discuss briefly the current views on this condition. Acute dilatation was described first by Kundradt in 1871, and was soon recognized and commented upon by other people (Fagge, 1873; Rokitansky, 1861). Rokitansky suggested that it was caused by the dragging of the mesentery of the small intestine, which pressed upon and occluded the transverse portion of the duodenum. This theory has persisted till recently, but it is surprising to find it still in modern textbooks. It is difficult to conceive how the occlusion of the duodenum can bring about acute dilatation of the stomach when the case described below is considered. Most of the reported cases follow operations, but there are many accounts of the disease arising apart from operation—e.g., during a severe wasting disease (Herrick, 1906)—and the condition has been known to occur in healthy individuals as the result of overeating (Gillette, 1930). It has also been reported following childbirth and severe blows to the abdomen.

Dragstedt and others (1931) state that acute dilatation is rare after operations upon the stomach itself, and we have considered it noteworthy to report a case following an operation of partial gastrectomy, as no such case could be found in the literature.

There are many peculiarities in respect of acute dilatation. The first striking feature is the enormous amount of fluid from the stomach: where does it come from? One opinion is that the stomach is able to hold all this fluid because it has become paralysed as the result of reflex sympathetic stimulation. The suggestion has been put forward (Morris, 1882-3) that the enormous amount of fluid was the result of excessive secretion of the stomach mucosa—in other words, a gastrorrhoea. Certain factors discountenance this theory. For instance, in our own case, in which a large part of the stomach had been removed, it is difficult to understand how the remaining portion could secrete 8½ pints in twenty-four hours. Again, if the fluid aspirated or regurgitated came from the stomach alone it would contain hydrochloric acid, but examinations of the fluid show it to contain little or no free HCl. It always contains bile (Herrick, 1906; Dragstedt and Dragstedt, 1922).

The present-day view considers that the dilatation is neurogenic and is the result of paresis of the muscles of the stomach. We suggest that the enormous amounts of fluid collecting in these cases arise from the alimentary canal below. As the result of the stomach becoming paralysed and dilated a negative pressure is produced in its interior. The intra-alimentary pressure where the muscular tonus is normal is higher than the intragastric pressure, and fluid flows backwards into the stomach—in other words, there is a backwash. The fluid keeps on collecting, and when enough is present it wells up into the oesophagus, rises into the pharynx, and is eventually expelled. This theory is supported by the fact that in these cases there is actually no true vomiting. The fluid which comes away just pours out from the patient's mouth. There is no sign of its being discharged in an expulsive manner. Once the condition has been started it is easy to understand why it should continue and how quickly the patient loses fluid. Not only fluid is lost but also valuable substances which are absorbed naturally lower down in the intestine and which are essential to retain the normal equilibrium of the blood. It is the loss of these valuable substances from the blood stream that is the real cause of death in these cases. There is no doubt that after operations acute dilatation of the stomach is of frequent occurrence in minor degrees, just as paralytic ileus is. It is difficult to understand why some cases should develop acute dilatation and others paralytic ileus. Fortunately these minor cases tend to right themselves. Factors which may make one suspicious that acute dilatation (or paralytic ileus) is developing are that the pulse rate is not lessening as expected after an operation, or that it is rising after having been lower for a short while. Or, again, the patient may complain of being uncomfortable under the bandages or show some uneasiness in his epigastric region. These cases should be met by passing a duodenal tube and leaving it in. This process of "sounding the stomach" is of the greatest assistance.

Case Report

The patient, a thin man aged 64, gave a history of abdominal pain in relation to meals for the last twenty years. He had noticed recently that his stools were often tarry. For the past six to twelve months vomiting had become more frequent and of greater volume; it relieved pain. A barium meal revealed great delay in emptying time. Gastroscopic examination showed chronic gastritis and pyloric stenosis, but no ulcer was seen. Occult blood ++ was found in the stools. A test meal disclosed a very high content of free acid.

The patient has had extensive medical treatment at other places, but without improvement. On January 31, 1941, a partial gastrectomy under spinal anæsthesia and gas-and-oxygen was carried out. A large-sized duodenal ulcer was seen. At the end of the operation the patient's condition was satisfactory: the pulse had fallen from 120 to 100. Twenty hours after the operation the pulse rate began to rise slowly, though the patient was comfortable and did not complain of symptoms. Thirty hours after operation the pulse rate had risen to 120 and he had a feeling of distension in the epigastrium. At this time he spat out 2 oz. of dark brown fluid which he said "just came up into my mouth." Acute dilatation was suspected, and the stomach was sounded by means of a Ryle tube. 30 oz. of fluid was aspirated. A continuous gastric drainage apparatus was set up and an intravenous drip was started. Morphine grain 1/4 four-hourly was administered, and the bed was raised two feet at the bottom. Within twenty-four hours from beginning the aspiration 8½ pints of fluid were withdrawn and the pulse came down to 80.

Summary and Conclusions

A case of acute dilatation of the stomach following a partial gastrectomy is described. In view of this condition following a partial gastrectomy the previous theory of compression of the third part of the duodenum by the mesentery is proved to be wrong.

The present theory that acute dilatation is neurogenic in origin is one which is now accepted. We have come to consider that this condition and paralytic ileus are very closely related, the only difference being that one is a pathological state of the stomach and the other a pathological state of the alimentary canal lower down. A theory as to the origin of the large amount of fluid expelled is given.

The value of "sounding the stomach" in the early stages of the condition is stressed.

Clinical Memoranda

Capillary Fragility and Vitamin C in 40 Children of Different Classes

By dietary experiments on a man and a woman whose capillary resistance to rupture was initially normal Göthlin (1937) was able to show that subsistence on a diet poor in vitamin C gradually gives rise to capillary fragility. The change proved to be reversible, for with increasing doses of fresh orange juice the strength of the cutaneous capillaries returned to normal. In 1931 Göthlin found that 5.9 to 21.5% of his children gave a positive capillary resistance reaction. In all cases their diets were deficient in vitamin C. He gave these children 60 to 120 c.cm. of orange juice a day, and yet only 50% of them showed any definite rise of capillary resistance. From this he concluded that although lack of vitamin C was a definite factor in lowering the capillary resistance there were other factors to be considered. In 1935 Dalldorf and Russell investigated a series of 24 persons with subclinical scurvy. They injected 100 mg. of ascorbic acid in 21 cases and 50 mg. in 3 cases. All showed an immediate rise of capillary resistance between 10 and 20 mm. Hg. using Dalldorf's technique. Since then St. Rusznyák and Szent-Gyorgyi (1936), and Scarborough and Stewart (1936) have suggested that vitamin P (hesperidin) was responsible for increased capillary fragility; but that has been disputed by Zilva (1937).

THE INVESTIGATION

To discover the relation of capillary resistance to vitamin C and to investigate this difference in various social groups we studied the capillary fragility of 40 unselected healthy children. The method adopted was a modification of Bell, Lazarus, and Munro's (1940) adaptation of Göthlin's test. This modification was necessitated by the small size of the children's arms. A circle 6 cm. in diameter was made on the anterior cubital fossa; the skin on the area was examined, and any blemish resembling petechiae was marked on the skin. The subject was seated in a chair with the arms resting on a table at the level of the heart. The longitudinally folded band of a sphygmomanometer was wrapped round the upper arm, the lower edge of the bag being kept at least half an inch above the circle. Pressure of 50 mm. Hg was maintained for fifteen minutes. After the skin had returned to its normal colour petechiae in the circle were counted by each of us independently, and the average taken. A 300-watt lamp, two feet from the arm, was used for the inspection of the cubital fossa, and the room was kept at a comfortable temperature. Several of the normal children were tested on two separate occasions, but the results at both times were practically identical.

As Göthlin (1931) and Bell *et al.* (1940) have shown, over eight petechiae in the circle represent a definite increase in capillary fragility.

Results.—A total of 40 unselected healthy children between the ages of 1½ and 6 years were examined. Class A were 10 children from a private school; Class B were 20 children from the poor quarters of Newcastle-upon-Tyne; and Class C 10 children from a day nursery. Therefore the nutrition of Class A could be considered as excellent, of Class B poor, and of Class C intermediate, as the children of this class obtained better food than Class B whenever they attended the day nursery.

TABLE I.—*Distribution of Children according to Number of Petechiae in the Circle shown at the First Test*

	No. of Petechiae												
	2	3	4	5	6	7	8	9	10	11	12	13	14
Class A (10)	—	2	1	4	1	1	1						
,, B (20)	1	1	2	2	2	3	3	2	—	—	2	1	1
,, C (10)	1	3	1	1	2	—	—	—	2				
Total (40)	2	6	4	7	5	4	4	2	2	—	2	1	1

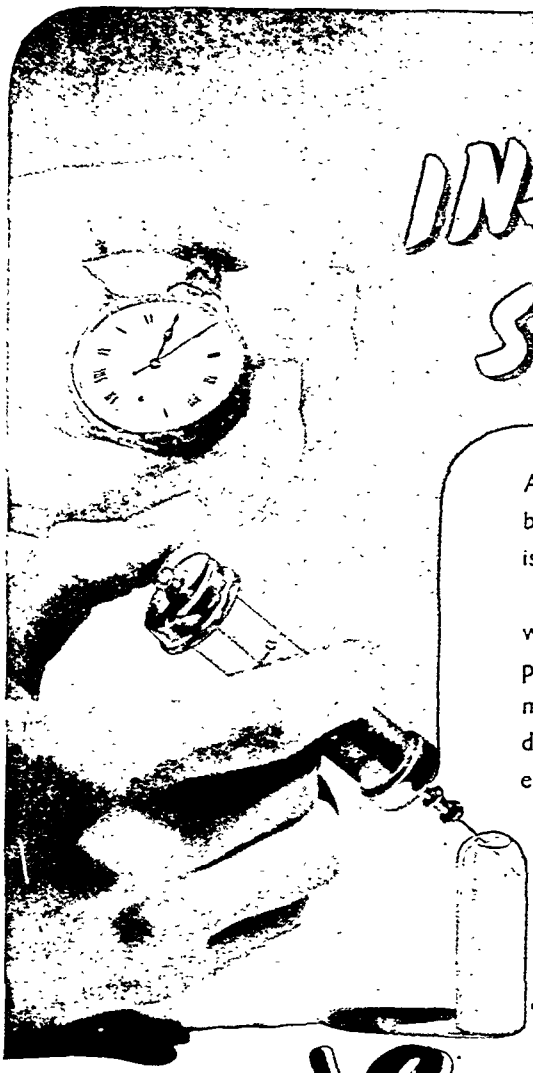
TABLE II.—*Result of Administration of Ascorbic Acid in the 8 Children with Initial Increased Capillary Fragility*

Initial Petechial Count	Petechial Count After Treatment for 1 Week	Petechial Count After Treatment for 2 Weeks
13	4	—
14	11	7
9	6	—
12	4	—
12	5	—
9	4	—
10	5	—
10	4	—

Table I shows that 8 of the 40 healthy children had a definite increase in fragility of the capillaries. These 8 children were re-examined for capillary fragility after the administration of 100 mg. of ascorbic acid (redoxon) daily for a period of one week. Table II shows that after the administration of ascorbic acid all the 8 children were definitely improved, the capillary resistance being normal to 7 out of 8. To the one child who still had abnormal fragility, ascorbic acid 100 mg. daily was given for a second week, after which she showed normal capillary resistance. All children of Class A had normal capillary resistance; while in 33% of Class B and 25% of Class C it was definitely increased.

DISCUSSION

This series shows that capillary resistance to pressure is greatly affected by vitamin C, and that the abnormal fragility of the capillaries can be improved by the administration of ascorbic acid in sufficient doses. The capillary resistance is normal in healthy children of the better classes, and it decreases as the diet deteriorates. This fact may suggest that nutrition, and probably vitamin C, play an important part in capillary fragility.



If the capillary resistance test can be considered to be an index of the amount of vitamin C sufficiency or deficiency in the healthy children, then our results compare favourably with the findings of Prof. Harris (1940) in Cambridge children, as determined by his methods of urine analysis. The capillary resistance test may therefore have great scope in the assessment of adequacy in routine school medical examinations.

We are grateful to Dr. A. J. Smith for his generous help in this work.

CAUSAL MECHANISMS OF DEVELOPMENT

Organisers and Genes. By C. H. Waddington, Sc.D. (Pp. 160. 12s. 6d. net.) Cambridge: The University Press. 1940.

For at least twenty years the need has been felt for a synthesis of the results of genetic and embryological experiments. Genetics alone remains formal, a science of ratios, a schematic representation of certain aspects of reproduction and hereditary transmission. Embryology alone remains, for the most part, descriptive, lacking the fabric of ordered hypothesis and theory. The present book will therefore be welcomed as a praiseworthy effort to present "a general framework for our ideas on the causal mechanisms of development." The aspect of embryology particularly considered is that of embryonic induction, about which knowledge has increased rapidly in recent years; a field, moreover, in which Dr. Waddington has himself made notable contributions. The reader who is unfamiliar with this subject will find himself on ground which is far from easy, and may at first feel bewildered by the complexities of evocation, individuation, competence, and the like. Similarly, the reader whose knowledge of genetics is slight will face a stiff task, though here, too, the argument, if closely reasoned and condensed, is clear. Careful reading is required, but will repay the effort. Many will doubtless feel some disappointment that more has not been accomplished, that more cannot be said. It should be emphasized, however, that the fault, if it is a fault, is not that of the author. He has presented a thoroughly able thesis, and one which is complete and up to date. A synthesis has been attempted, and with success, but it is clear that, if the foundations have been truly laid, future years will see much greater advances than those already made.

The reader is urged not to look at the frontispiece, entitled "The Epigenetic Landscape," till he has read page 93. We had no one to give us this advice, and kept turning back only to be baffled again and again; and to be reminded of some lines of unhappy inspiration that once called down the thunderbolts of Macaulay:

> "The soul, aspiring, pants its source to mount,
> As streams meander level with their fount."

After all this the sentence on page 93, "It would be difficult to find a similar configuration in any actual piece of country," seemed a masterpiece of understatement. If the reader, however, curbs his impatience he will be rewarded with a not unhelpful similitude and will spare himself, as we did not, a considerable headache.

GASTRIC AND DUODENAL ULCERS

Gastric and Duodenal Ulcers. By Harold Avery, D.Sc., M.B., M.R.C.P. (Pp. 110; illustrated. 7s. 6d. net.) London: John Bale and Staples, Ltd. 1941.

This book, according to the author, was written because of the difficulty of finding concise information on the subject of gastric and duodenal ulcer in a single volume. Unfortunately, the fifty-three small pages in the book which are devoted to symptoms, diagnosis, and treatment give no more satisfactory information than that provided by several textbooks on general medicine. There are neither references nor bibliography—a serious omission from a monograph, however small.

The book opens with a badly illustrated account of the anatomy and physiology of the stomach. This is followed by a short chapter on the pathology of ulcer, illustrated by four deplorable sketches. After an account of the aetiology a short description of the clinical history is given. The chapter on clinical examination, including radiology, is accompanied by only two radiographs, neither of which is very good. The chemical, but not the more accurate spectroscopic, methods of examining for occult blood are described, and the necessity for eliminating chlorophyll from the diet is not mentioned.

Dr. Avery does not appear to have any decided views on the subject of treatment. He gives prescriptions for three different alkaline powders without indicating under what conditions each should be used. The dose of tinct. belladonnae is given as 5 minims, which is too small to have any effect on secretion or motility in the majority of cases, and the hypodermic injection of grain 1/75 of atropine at night is recommended, though atropine can be equally well given by mouth. The author has an unfortunate liking for proprietary preparations of doubtful value, and he recommends the quite unnecessary addition of copper and manganese to iron in the treatment of anaemia. The advice that transfusion should be given, in cases of haemorrhage requiring surgery, only after the bleeding-point has been secured will not be shared by many surgeons, who naturally prefer that the patient's haemoglobin should be brought to a safe level before beginning the operation.

In discussing hour-glass contraction the four physical signs collected by Moynihan in 1904 are described, although in practice they were found useless in the days before the x rays rendered the search for signs superfluous. Dr. Avery states that blood from a duodenal ulcer is rarely vomited—an extraordinary statement in view of the fact that duodenal ulcer is the commonest of all causes of haematemesis.

THE EYE IN MEDICO-LEGAL PRACTICE

A Treatise on Medicolegal Ophthalmology. By Albert C. Snell, M.D. (Pp. 312. 30s. net.) St. Louis: The C. V. Mosby Company. 1940.

No monograph has been published in this country on the medico-legal relations of the ophthalmologist; and indeed the general practitioner of medicine or law might find it difficult to imagine what would fill a fair-sized book on this subject. He might guess correctly that the matter would practically all be concerned, directly or indirectly, with compensation, chiefly of injured workmen and secondarily of persons injured by negligence or malice, or of candidates for pensions. Even in that restricted field Dr. Snell shows how large the subject is. His first three chapters, it is true, deal with general law—the position of the medical witness, the legal duties of a physician, and the law relating to negligence. He also traces the historical development of liability and compensation laws in America, and the laws relating to vision which have been passed both by the Federal legislature and by the various States. The middle section of the book, which is his individual contribution to the science of forensic ophthalmology and perhaps its most important part, deals with the evaluation of visual disabilities and the determination of fractional parts of vision. Acuity notations, of course, are not expressions of fractional parts of vision, and the fractional form of recording acuity of vision devised by Herman Snellen in 1862 and now in universal use does not represent the remaining fraction of the normal vision.

Dr. Snell summarizes the various attempts that have been made to estimate visual function and points out their drawbacks. The problem has been extensively studied in the United States, especially by the Section of Ophthalmology of the American Medical Association, and Dr. Snell reprints the report of its committee on compensation for eye injuries. This sets forth a method of appraisal

of visual efficiency which has been accepted as a standard by nearly all American ophthalmologists, and he recommends its more general use in order to secure a greater degree of uniformity among the various States in computing indemnity for visual disability. Other chapters of this elaborate study are devoted to examination of injured eyes, malingering, and suggestions for the improvement of the compensation laws. For the English reader about half this book is irrelevant, as it deals with American law and procedure. The other half, however, is obviously of great value. The workmen's compensation laws of the two countries are sufficiently alike to make the general practical purpose of the book applicable here, and the medical rather than the legal side should greatly assist ophthalmologists who have much insurance practice.

COMMUNITY HYGIENE

Community Hygiene. By Elizabeth Sterling Soule, R.N., M.A., and Christine Mackenzie, R.N., M.A. (Pp. 218. 7s. 6d. net.) New York: The Macmillan Company. 1941.

Professor Elizabeth Soule and Instructress Christine Mackenzie of the University of Washington present in their recently issued book entitled *Community Hygiene* a brief but well-informed survey of public health activities in the United States to-day. Among the chapter headings are Food Control, Water Supply, Sewage Disposal, Housing, Communicable Diseases, Maternity, Infancy and Childhood, and Industrial Hygiene. We have found no errors in what is said, and no omission of significance. The important points are well brought out, and the style of writing is lucid and graceful. Though it modestly claims to be but a manual for student nurses at Washington, *Community Hygiene* is well worthy of a wider circle of readers, even including students and practitioners of medicine on this side of the Atlantic, many of whom might derive an enhanced appreciation of the aims and achievements of hygiene from this pleasant book.

Notes on Books

The ninth edition of *Bainbridge and Menzies' Essentials of Physiology*, edited by H. Hartridge, M.D., F.R.S., is published by Longmans, Green and Co. at 16s. This book is popular with students on account of its small bulk. On that account also its style is brief to the point of dreariness. Much recent matter has been included in the present edition, but some obsolete matter is still to be found, and certain important new items have been omitted. For instance, under the functions of the adrenals, the now discarded view of the failure of respiration after adrenalectomy is not only mentioned but supported by a figure in the text. Yet under the same heading there is no mention of the now well recognized and clinically employed cortical steroids. Misspellings, such as that of "phosphorelation" for "phosphorylation" on the same page, are frequent (e.g., "odenyl" for "adenyl" on p. 543). There are numerous instances of loose or inaccurate statements throughout the book, and most of these are to be attributed to the extreme compression to which the matter has been subjected. Some new figures have been introduced, and these are clearly drawn; it is a pity there are not more of them, and either a less ambitious text or a fuller exposition throughout. The general get-up of the work is excellent, and the index adequate.

Modern Treatment in General Practice Year Book 1941 is edited by Mr. CECIL P. G. WAKELEY, who writes a preface, and it is a collection of short miscellaneous papers on therapeutics reprinted from the *Medical Press and Circular*, which publishes the volume at 12s. 6d. from the office of Baillière, Tindall and Cox. The first and larger part of the book is made up of thirty-one signed contributions on subjects ranging from haematemesis to dental cysts. The concluding section comprises twelve signed articles grouped together under the heading "War Medicine and Surgery." Some of the articles are illustrated, and there is an index.

Mr. ALECK BOURNE'S *Synopsis of Obstetrics and Gynaecology*, first published in 1913, has now reached an eighth edition (John Wright and Sons, Ltd., 15s.). The general plan is maintained, but the text has undergone a good deal of revision and some parts have been largely rewritten. There is a new section on post-natal care. In his preface the author expresses the hope that this book may still be helpful to students for revision and to practitioners as a means for quick reference. We think it will.

Preparations and Appliances

TROCAR FOR INTRODUCING REINFORCED MALECOT OR DE PEZZA TUBE THROUGH THE BLADDER WALL

Mr. H. P. WINSBURY-WHITE, F.R.C.S. (London, W.1) writes:

The trocar illustrated herewith is really a modification of the instrument made some years ago for the late Frank Kidd. The point of the trocar is passed down the tube and made to perforate the central reinforced button at the vesical end of the former. After the distended bladder has been exposed

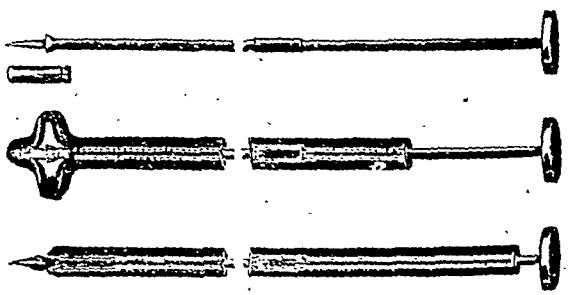

FIG. 1.

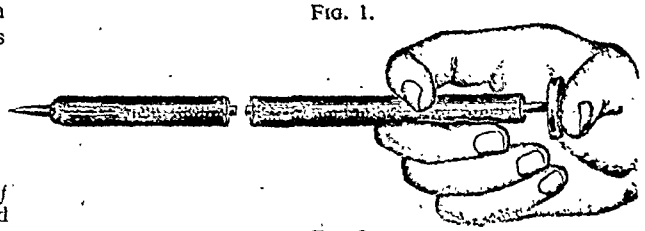

FIG. 2.

the tube is put on the stretch with the fingers and thumb as shown in Fig. 2. The point of the trocar and adjacent part of the tube are then forced firmly through the exposed bladder wall. The trocar is next quickly withdrawn while the tube is held securely just outside of the bladder. This form of trocar can be disengaged from the tube more quickly than the old pattern instrument; thus a minimum amount of fluid is allowed to escape.

If gradual decompression of the bladder is necessary, the tube is spigoted as soon as the trocar is withdrawn. As the tube is on the stretch when it is introduced, it re-expands the moment it is released and in this way makes a completely watertight junction with the bladder wall, so bringing decompression under complete control. Because of its length the trocar is made in two equal parts which unscrew for convenience in travelling and sterilizing.

The instrument has been made for me by the Genito-Urinary Manufacturing Company of London.

ASCORBIC ACID FOR INFANTS

British Drug Houses Ltd. now supply tablets of vitamin C for infants, so as to provide ascorbic acid in a convenient form and thus counter the shortage of oranges. Each tablet contains 5 mg. of pure vitamin C and is equivalent to about two teaspoonfuls of orange juice. It dissolves readily in warm milk or in the infant's feed. The tablets are put up in bottles of fifty.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY MAY 17 1941

NOTICE TO READERS

To-day's issue of the BRITISH MEDICAL JOURNAL *has been prepared and passed for press under conditions of very great difficulty brought about by exigencies of war. Readers and contributors are asked to overlook imperfections in the* JOURNAL *as now printed in a different type-face, and to understand that much current material is perforce missing.*

It may now be stated that British Medical Association House suffered severe damage in one of the recent air raids on London; but work continues in all the departments.

ENDOCRINE INTERACTIONS

When Claude Bernard, from his study of the glycogenic function of the liver, first formulated the conception of internal secretion as a process by which the constancy of the internal environment was ensured, the real profundity of his generalization was not fully appreciated. Yet every subsequent advance in endocrinology has borne it out, and Dr. W. Cramer[1] has reviewed and added to our knowledge of this balance. He regards the endocrine glands as functionally one system consisting of a number of interacting units, in much the same way as Aschoff regarded various groups of cells in different organs as forming a coherent reticulo-endothelial system. The former is, however, much more varied in its responses, for some of its members are synergists and others are antagonists. If one of these glands is stimulated the internal environment is altered, and in order to restore the balance there is a secondary compensatory response in other glands, the antagonists being stimulated and the synergists inhibited. When the primary change is an inhibition or dysfunction the compensatory response is in the reverse direction—that is, antagonists are inhibited and synergists stimulated.

After showing how completely this idea is exemplified by recent knowledge concerning the classical example—that of the glycogenic function of the liver—Dr. Cramer goes on to elaborate it in connexion with the sex hormones. Prolonged experimental oestrinization gradually induces a syndrome resembling Simmonds's disease, yet the anterior pituitary is enlarged and deeply congested, while histologically it approaches the appearance of a chromophobe adenoma. This can be explained only by the supposition that the oestrogen arouses the anterior pituitary to a compensatory reaction which it nevertheless antagonizes and overcomes. That this is the true explanation is shown by the failure of the Simmonds syndrome to appear if oestrogenic and anterior pituitary hormones are injected simultaneously. On the other hand, the effect on the adrenal cortex of prolonged oestrinization is a specific degeneration of the innermost zone of the cortex, which on the view that the ovary and the adrenal cortex are synergists is what would be expected. It is further supported by the fact that if oestrinization is started a few weeks before adrenalectomy is performed in mice the mortality after operation is greatly diminished. Moreover, Woolley and others[2] found that spayed mice developed massive hyperplasia of the adrenal cortex. Thus hyperfunction of one gland leads to hypofunction of its synergists, and vice versa. On similar lines he attributes status lymphaticus to adrenocortical hypofunction. The adrenal medulla, though much less active in this connexion, appears to be antagonistic both to its own cortex and to the ovary. Cramer develops an interesting speculation based on these observations as to the influence of the synergist ovary and adrenal cortex on the development of mammary cancer, and of the antagonist anterior pituitary and adrenal medulla on mammary involution. He maintains, however, that the therapeutic value of the oestrogenic hormones is so high that their use should not be discredited on this account, as there is no risk of inducing cancer thereby so long as they are given over short periods of several months in doses just sufficient to produce the desired therapeutic effect. From a study of its effects on other glands he is of opinion that the follicular hormone embraces a wider range of endocrine activities than that of any other single hormone, in which respect it is in striking contrast with the male hormone testosterone, in spite of the close chemical similarity between them. An excessive supply of testosterone does not produce any of the effects on the pituitary and adrenal cortex which can be induced by very small doses of oestradiol, though, on the other hand, castration leads to some degeneration in the anterior pituitary (which disappears when testosterone is given) and degeneration in the adrenal medulla.

Dr. Cramer will not allow that the anterior pituitary is "the leader of the endocrine orchestra,"[3] considering that the pituitary is deeply influenced by the female member of that orchestra. (Presumably, then, the pituitary is more independent in men.) But this ignores not only the evidence for the dominant position of the pituitary adduced by Prof. E. C. Dodds in his Goulstonian Lectures in 1934 but the whole question of the part played by the autonomic nervous system. On that all he has to say is, "There is abundant evidence that the functional activity of some endocrine organs affects the mind and can in turn be affected by the mind." Now *a priori* one would hardly expect that, after the nervous system had succeeded in imposing increasing control over increasingly complex organisms as they evolved, it would abdicate in favour of chemotropisms. No doubt there is an autonomous ebb and flow of endocrine activity according to immediate biochemical requirements, but the blending of neural and glandular structures alike in the pituitary and adrenal in itself suggests some nervous control. The basal ganglia are the seat of emotional expression, and the pituitary-hypothalamic apparatus is now regarded as a unit where nervous mechanisms can be transformed into chemical ones. Moreover, the hypothalamus is also generally considered to be the head ganglion of the sympathetic, so that there is another route by which the emotions may influence the endocrine system, as they undoubtedly do. Now that we know, thanks to Dale and to Loewi, that this translation of nervous activity into chemical mechanisms occurs at every nerve-ending throughout the body, we may fairly

[1] *Bull. N.Y. Acad. Med.*, January, 1941, p. 5

[2] *Proc. Soc. Exper. Biol. & Med.*, 1939, 25, 277.

[3] Laughton-Brown, W., *Harveian Oration*, 1935, Camb. Univ. Press.

apply it to the endocrine system. Indeed, we may view it as integrated through the autonomic nervous system, and if the pituitary is the leader of its orchestra the hypothalamus is its conductor. This is not to deny the value and interest of Dr. Cramer's paper, which may be read in conjunction with Dr. P. E. Smith's article[4] on the relationship of the anterior pituitary to the other endocrine glands. This is an admirable review of our present knowledge which, while admitting the principle of antagonisms, does not dethrone the pituitary in favour of a matriarchal system. He also lays stress on a very important though neglected aspect—the selective capacity of the end-organ to respond to a hormone, which must play an essential part in the action and interrelations of the endocrine glands. As yet we know hardly anything of the nature of this selective capacity.

MEASURING GENIUS

More than thirty years ago Prof. Terman[5] became interested in the problem of what highly gifted persons are like during their early life. He perceived that the techniques of mental testing then being perfected offered the opportunity of attacking the question in the reverse way also. Using the new methods it became possible to select groups of children of the highest performance and then to follow their subsequent history. Preliminary observations along both lines soon convinced him that traditional beliefs on the subject were often little more than hallowed superstitions. Thorough investigation was certain to prove very expensive, but by great good fortune the genius of Prof. Terman found its complement in the generosity of the Commonwealth Fund, and twenty years ago there was initiated a scheme of research which for brilliance of conception, for thoroughness of execution, and for the fruitfulness and fascination of its results can seldom have been surpassed. It is to be hoped that many more volumes will be added to that fine series, *Genetic Studies of Genius*, in which the results are being recorded.

The first task of the Stanford workers was to select the most gifted Californian children of their time; these numbered 1,300—about 0.5% of the population. The physical and mental characteristics of the children composing the group were described in exhaustive detail in the first volume to be issued by the Stanford University Press.[6] The essential part of the plan was, of course, to re-examine these individuals at intervals and to discover what they were making of their lives. It is a fortunate circumstance that an outcry about inquisitorial and prying methods, that Press-fed menace to the betterment of human beings by research upon themselves, is likely to be least in evidence when the circumstance which has attracted the notice of the investigator is the extreme brilliance of the subject. Also, no doubt, comparative freedom from such prejudices is one of the blessings of a new country. In any event Prof. Terman, after the lapse of nearly twenty years, is still in touch with more than 95% of his group. The first re-examination took place after two years; a very comprehensive re-examination after six years filled another volume. Now we hear of a follow-up after more than fifteen years, the median age of a younger group being 27 years and of an older group 33. To the question whether the intellectual superiority of the group has been maintained, Prof. Terman says that the answer is emphatically yes. But the careers of the subjects have differed widely. At one extreme we hear of outstanding successes in various fields, and a flood of books and papers in learned journals; at the other extreme there are many who occupy humble positions.

What factors influence the translation of native intelligence into achievement and eminence? The advocates of sex equality will be sad to learn that sex is still an enormously important factor. Even if she does not marry the highly gifted girl tends to "accept whatever kind of respectable employment is at hand." So much is this so that the analyses now to be mentioned apply to the men only. Two groups were selected—A and C, the top and bottom 25%. The criterion, carefully applied, was the extent to which the individual had made use of his gifts: 90% of the A's graduated from college, only 50% of the C's; 96% of the A's were professionally or semi-professionally employed, only 28% of the C's. One important difference lay in the home background. There was a tradition of education in A homes. In line with this it was found that the heavy pressure to succeed in Jewish families ensured more accomplishment per unit of intelligence than was found in any other racial stock. Another very interesting distinction lay in the greater emotional stability of the A's; and a most important point is that it can now be seen that this difference was already detectable in the young child. No doubt as a consequence of this difference the A's marry younger, marry better, make better marital adjustments, and divorce is three times less common than among the C's. Already 300 children of these gifted persons have been tested and yield a mean intelligence quotient of 127, as compared with 150 for the group itself. It is striking that at these extreme levels the regression coefficient should still be in the neighbourhood of 0.5.

There is no space to refer to the other and fascinating aspect of these investigations—historical studies of 300 of the most eminent persons in history. But one most instructive point must not be omitted. Prof. Terman states that he was led to appreciate the importance of sound psychology in biographical studies and to apply for funds for this research by a striking piece of erroneous interpretation on the part of no less gifted and acute an observer than Karl Pearson. Pearson in his biography of Galton stated that the latter learned to read at the age of 2½ years, wrote a letter before he was 4, at 5 could read almost any English book and some French, could do any sum in addition, knew English money, and could tell the time by the clock. Pearson merely concluded: "I do not think that we can say more than that Francis Galton was a normal child with rather more than average ability." It can safely be concluded that his intelligence quotient must have been in the neighbourhood of 200, a level that not more than one person in 50,000 could attain.

In his conclusions Prof. Terman is commendably cautious; some of his more important generalizations are as follows. The typical genius is not an indomitable spirit driving on a frail body; he is healthy above the average. The typical genius is not one

[4] *J. Amer. med. Ass.*, 1940, 115, 1991.
[5] *Science*, 1940, 92, 295.
[6] *Genetic Studies of Genius*, vol. i, by L. M. Terman and others, 1925. Stanford University Press.

whose astonishing talents are confined to a single narrow interest and who is stupid at everything else ; he is highly versatile and capable of achieving success in many fields. The typical genius is not as a child the fool of the family, developing late, much to the amazement of his parents, nurses, and teachers: he displays his high gifts as soon as they can be observed and measured ; the typical genius is not a frustrated miserable being frenziedly dragging forth his gifts to mankind from the blackened recesses of a tortured soul: he is well adjusted, cheerful, happily married, and devotes himself contentedly to his work, his hobbies, and his home. Thus Prof. Terman. But there remains the difficult problem of how we should define the word "genius," a problem which of course he has not shirked. Perhaps it may yet be found that the very extremes of human achievement may not infrequently be associated with physical disability or mental unbalance—it is not hard to recall individual instances—but Prof. Terman appears to have produced very weighty evidence to the contrary when the criterion is measurable mental ability of a very high order, or when it is eminence which is extreme without perhaps being superlative.

SULPHONAMIDES FOR LUPUS ERYTHEMATOSUS

H. W. Barber, in an excellent and interesting paper,[1] shows that lupus erythematosus is often amenable to treatment with the sulphonamides. It is true that, by the employment of the heavy metals, considerable progress had been made in recent years with the therapy of lupus erythematosus. Both gold and bismuth have proved their value in dealing with it, but the results are by no means always satisfactory, and on that account alone a new line of approach to treatment is welcome. Barber has always been of opinion that lupus erythematosus must be regarded, not as a definite disease having always the same aetiology, but as a form of clinical reaction to various infective agents. He considers the streptococcus to be prominent among these, though he admits that the tubercle bacillus may in some cases be the root of the evil. He has always insisted on the importance of the removal of all obvious septic foci in streptococcal cases, and in cases of comparatively short duration the results are often very good. He admits disappointment, however, in cases of long standing. The failure, he thinks, is due at least partially to the existence of subsidiary foci not accessible to surgical removal. He believes that by the use of the sulphonamides he can attack the entrenched bacillus in situations otherwise impregnable, and the clinical cases which he quotes strongly support his contention: he has used sulphanilamide and sulphapyridine, the latter most often. A characteristic reaction appears about eight to ten days after starting treatment with these compounds, consisting of fever, focal reaction in the patches, and muscular pains. This phase is followed by lessening of the eruption. The reaction is regarded by some observers as similar to a serum reaction, but Barber thinks that it is due to the effect of the drug on the streptococci themselves, dissolving their capsules and liberating toxins the absorption of which causes the clinical symptoms mentioned. Subsequent doses of the sulphonamide usually cause progressively less severe reactions, because there are fewer organisms remaining to be destroyed. Barber brings forward evidence which tends to show that in some cases the streptococci responsible for the eruption are resident in the bowel. So many varieties of micro-organisms seem to be able to live there without causing much trouble to their host that one is inclined to doubt the pathogenicity of faecal streptococci, but Barber still thinks that in certain cases they are important. In cases where there is reason to suppose that the disease is due to a tuberculous infection these reactions do not occur, nor is the eruption improved. Barber's observations extend over some three years or more, and he states that he is now able to predict in selected cases the train of events which will follow the administration of sulphapyridine. There is no doubt that he has made a valuable contribution to the therapy of lupus erythematosus.

CLINICAL MEASURE OF PULMONARY ELASTICITY

To measure the elasticity of a substance two factors must be determined: (1) the force producing distortion and (2) the amount of that distortion. In the case of the lungs the first of these can be ascertained from the changes in intrapleural pressure occurring with respiration, and the second from the changes in the volume of the lungs during respiration. Both factors must, of course, be determined simultaneously. On the basis of experiments carried out in living animals by Cleotta[1] in 1913 two different methods of measuring the elasticity of the lungs in living patients have been described by v. Neergaard and Wirz[2] and by Christie and McIntosh.[3] The former determined the intrapleural pressure at those points in the respiratory cycle when the elastic forces within the lungs and thorax are in static equilibrium. By means of optical manometers on a moving photographic film the intrapleural pressure and the velocity of air flow in the trachea were measured at the same time. From the curves thus produced the authors ascertained the phase-change points on the intrapleural pressure curve, the volume of tidal air, and the "factor of elasticity." In order to take into account the variation in size of the lungs in different persons they advised that the volume of the lung in expiration should be calculated from a radiograph of the chest by the formula of Rohrer.[4] Christie and McIntosh registered simultaneously the volume of tidal air and the intrapleural pressure. They consider that the maximum change in intrapleural pressure between expiration and inspiration, as measured in centimetres of water, divided by the volume of tidal air in 100 c.cm. corresponding to that change in pressure, is a measure of elasticity, which they called the "unit of pulmonary distensibility." Whereas this value varied considerably in different individuals, it was remarkably constant in the same person and was independent of changes in the tidal air. To correct for this variation, due, among other things, to differences in the size of the lungs, and to furnish a normal standard of comparison between individuals, the "coefficient of distensibility" was adopted. This was defined as the change in the intrapleural pressure which accompanies ordinary inspiration. J. R. Paine,[5] who has recently investigated the elasticity of the lungs in twenty-three patients by both these methods, found that of Christie and McIntosh to be superior to that of v. Neergaard and Wirz, the technique being simpler and the results more consistent. In eight patients whose lungs were thought to be normal the change in intrapleural pressure accompanying an increase in the volume of the lungs of 100 c.cm. (unit of pulmonary distensibility)

1 Arch. ges. Physiol., 1913, 152, 359.
2 Z. klin. Med., 1927, 105, 35, 51.
3 J. clin. Invest., 1934, 13, 979.
4 Arch. ges. Physiol., 1926, 165, 445.
5 J. thorac. Surg., 1940, 9, 330.

varied from 0.79 to 1.56. The change accompanying an ordinary inspiration (coefficient of pulmonary distensibility) in the same patients varied from 3.4 to 7.6. The latter is considered by Paine to be the best measure of pulmonary elasticity. Out of ten patients with bronchial asthma, chronic bronchitis, or both, nine showed decreased pulmonary elasticity, the decrease being marked in seven of them. Slight pulmonary emphysema cannot be diagnosed with certainty by *x*-ray examination, but it was found that where the emphysema was extensive the radiological interpretation of chest films correlated well with the measurement of pulmonary elasticity. In eight patients with moderate to severe emphysema as determined by *x*-ray examination, the unit of pulmonary distensibility was found to vary from 2.19 to 8.73 and the coefficient of pulmonary distensibility from 11.20 to 21.83.

ACACIA FOR THE NEPHROTIC SYNDROME

It is well known that in oedema of nephrotic type the serum proteins are diminished. This finding is common both in cases diagnosed as lipoid nephrosis and in cases of glomerulonephritis in the subacute stage, with persistent oedema. It is unnecessary to repeat here the reasons for believing that this reduction in serum protein (and therefore in colloid osmotic pressure) is an important cause of the oedema. This is the rationale of the high protein diet of intravenous acacia, and, more recently, of injections of concentrated human serum.

Hartmann[1] was the first to use acacia systematically, and reported good results in children. Later reports, however, varied considerably. Some workers have observed ill effects, including enlargement of the liver, so that with many physicians acacia treatment has fallen into disfavour. Goudsmit and Binger[2] at the Mayo Clinic have therefore made a careful study of the results of acacia treatment in forty adult patients. The preparation used was a 6% solution of gum acacia in 0.06% sodium chloride. Particulars are given of the method by which it is prepared; this is of great importance in the avoidance of unpleasant reactions. The solution is administered intravenously, in doses of about 500 c.cm., forty-five to seventy-five minutes being taken for the injection. This is repeated every day or every other day until a total dosage of 60 to 100 grammes of acacia (1½ to 2 grammes per kg. body weight) is reached. Other methods of treatment are combined with this, especially a high-protein salt-free diet, restriction of fluid intake to one litre or less, and the administration of diuretic salts, the one generally used being potassium nitrate in doses of 6 to 12 grammes daily. This salt is given by mouth in 1/2-gramme capsules, and should be begun three or four days before the injection of acacia. The importance of these accessory measures is stressed by the authors, but it is obvious from the case histories that the results could not have been achieved without the acacia. For instance, the first patient, after all other treatment had proved useless, lost 23½ lb. in weight after the first injection of 350 c.cm. of acacia solution. In forty cases there were only four which failed to respond by loss of all, or of practically all, the oedema. Some of the cases showed some degree of renal insufficiency, and no attempt was made to restrict the treatment to cases of pure nephrosis. The only undesirable effects were urticaria, thoracic discomfort, and fever; but they were never serious. The ill effects noted by other authors, including liver enlargement, were not observed. It is probable that when these occur they are due to the administration of too much acacia or to lack of care in its preparation. Failures were usually the result of the administration of insufficient diuretic salts or insufficient acacia, and of failure to control the anorexia and vomiting that sometimes occur in these patients. In the successful cases an average of from 1 to 3 lb. in weight was lost per day. A second course of treatment, if necessary, can be given after an interval. Reports so far published on the use of concentrated serum in renal oedema do not show consistently successful results, and in most laboratories the concentration presents technical difficulties. The use of acacia as a routine in the treatment of these obstinate cases therefore seems to be justified.

BUERGER'S DISEASE AND TYPHUS

Thrombo-angiitis obliterans, or Buerger's disease, is an unfamiliar though not altogether unknown condition in this country. It produces severe pain and ultimately gangrene of the lower extremities at an earlier stage in life than that of most degenerative arterial lesions, and is said to occur almost exclusively among Jews. It is not a degenerative but an inflammatory lesion, an arteritis leading to thrombosis with subsequent canalization. This fact alone strongly suggests an infective origin, and the suppositions that excessive use of tobacco or alcohol, changes in the viscosity, coagulability, or volume of the blood, or excessive consumption of salt are responsible in any way for the disease have little to support them. Both accidental and deliberate transmission of the disease by material from the lesion have also been known, a fact pointing strongly to the presence of a microbic cause. It was first suggested many years ago by C. Goodman that the disease may be a late manifestation of typhus, and he now[1] restates the evidence in favour of this hypothesis and adds to it. Some of this evidence is only suggestive; the lesion of typhus is, of course, vascular—although smaller vessels are attacked in the acute stage—and peripheral gangrene is recognized as a complication both of typhus and of other rickettsial infections. The belief that the disease is restricted to the Jewish race, which would of course introduce an aetiological factor hardly compatible with so positive a primary cause as typhus infection, is mistaken; in America it chiefly attacks recent immigrants from Eastern Europe, who often happen to be Jews, but who include Estonians and Russians; in Russia, Gentiles as well as Jews are attacked, and the Chinese and Japanese also suffer from it. More direct evidence is the alleged demonstration of rickettsial bodies in the vascular lesions, and the demonstration of cutaneous sensitivity to a rickettsia suspension in almost all of a large number of cases of thrombo-angiitis obliterans tested for this, with almost consistently negative results in control patients; the suspensions used gave similar results in patients known to have had typhus. Although our opportunities of studying this problem are fewer, the possibility of past typhus is perhaps worth while bearing in mind in cases of unexplained peripheral gangrene.

The next session of the General Medical Council will open on Tuesday, May 27, at 2 p.m., when the President, Mr. H. L. Eason, will take the chair and deliver an address.

1 *J. Mt. Sinai Hosp.*, N.Y., 1941, 7, 391.

The Governors of the Society of the New York Hospital, created by Royal Charter in 1771 in the reign of King George III, announce the recent completion at the New York Hospital, Westchester Division, White Plains, of the Nichols Memorial Cottage, in memory of Dr. Charles H. Nichols, attending physician 1849 to 1852, medical superintendent 1877 to 1889.

MEDICAL PLANNING COMMISSION

FIRST MEETING

SCOPE AND PROCEDURE DISCUSSED

The first meeting of the Medical Planning Commission, which has been set up by the British Medical Association, with the co-operation of the English Royal Colleges and the Scottish Corporations, to study wartime developments and their effects on the country's medical services both present and future, was held at the B.M.A. House, London, on May 7. More than sixty of the sixty-seven members of the Commission were present.

Welcome by Chairman of Council

Mr. H. S. SOUTTAR, in welcoming the members, said that he believed no body had ever met which had so fully represented the medical practice of the country in all its varied aspects. The problems of medical service after the war would be complex and difficult enough, but upon their solution would largely depend the health of the nation. It was the profession's desire that every individual should have at his service, whatever his economic status, all necessary medical resources. This country had gone a long way towards achieving that aim, for the whole population in industrial employment was included under national health insurance. There was a strong feeling that the service enjoyed by the worker should be extended to his dependants, which would mean that nearly 80% of the population would be included, and if, as had also been suggested, the insurance income limit were raised, possibly 95%—or some forty million individuals—would be cared for by this service. Moreover, there was a strong demand that a consultant and specialist service with full hospital facilities should be added. The provision of a complete medical service for 95% of the population constituted a problem of the first magnitude. It might be met by establishing a whole-time State Medical Service; this would be a complete break with the traditions of medical practice in this country, but it must be carefully examined. On the other hand, the present service might be developed, but here again the great changes which its extension would bring about had to be considered. On one point they would all agree, that everything within their power must be done to maintain the close personal relation between doctor and patient which had been characteristic of British medical practice.

Mr. Souttar concluded by saying that although the Commission had been initiated by the British Medical Association it was an entirely free body, not bound by the Association's policy. It would carry on its business as it determined, but the whole resources of the Association were at its disposal, including secretarial and clerical assistance. To assist discussion the secretariat had drawn up a memorandum, purely for information, embodying the views on practice accepted by the Association, as well as by other societies and individuals, also a bibliography of the more important literature on the subject.

Election of Chairman

On the motion of LORD DAWSON OF PENN, seconded by Sir ALFRED WEBB-JOHNSON, Mr. Souttar was unanimously elected to the chair of the Commission.

Additions to Membership

Suggestions from several bodies for special representation on the Commission were on the agenda.

In reply to Dr. G. F. BUCHAN, who asked what was the position of members in relation to the bodies by which some of them had been appointed, the CHAIRMAN said that none of the bodies represented was bound in any way by any report which the Commission might issue, unless, of course, it chose to adopt it. The speech or action of its representative did not bind any body. One request for representation which he thought should be acceded to was from the Medical Advisory Committee of the Nuffield Trust, which asked that its chairman, Sir Farquhar Buzzard, be appointed. He proposed that this suggestion be adopted. This was agreed to.

The CHAIRMAN said that the Ministry of Pensions desired to send an observer. The Ministry of Health and the Department of Health for Scotland had observers on the Commission. Dr. BUCHAN mentioned a number of other Government Departments and quasi-Government Departments with medical interests which might make a similar request, and said that he was not quite sure how far it was necessary or desirable to carry this principle. After a short debate it was agreed to postpone the consideration of this request until it was known whether and what other claims were made on behalf of official bodies.

Dr. E. A. GREGG said that the Insurance Acts Committee, of which he was chairman, had had before it many serious criticisms of the composition of the Commission, and was satisfied that there was considerable feeling throughout the country that general practitioners were not sufficiently represented. If additional general practitioners were appointed by a representative body it would go far to create a favourable atmosphere in the profession generally for the consideration of the reports which would eventually issue from the Commission. Dr. D. G. GREENFIELD spoke to the same effect, while admitting that there were a number of general practitioners on the Commission already.

The CHAIRMAN said that twenty-four members of the Commission might fairly be described as general practitioners; nevertheless, he had sympathy with the request of the Insurance Acts Committee. Dr. J. B. MILLER said that there was no criticism of the general practitioners already appointed except on the ground of their age, and even in that respect the experienced practitioner was perhaps more valuable on a commission of that kind than the young. But the feeling on the subject was due to the fact that practitioners as a body had had no opportunity to nominate representatives. Prof. R. M. F. PICKEN supported the proposal. Mr. BISHOP HARMAN said that while he sympathized with the view of the Insurance Acts Committee, he felt that the addition of a few members would make no difference to the influence which general practitioners would exercise on the findings of the Commission. Sir JAMES WALTON agreed that the real power would lie in the sectional committees, but what was now proposed would help to allay the criticism that the general practitioner, especially the rural practitioner, was not adequately represented. The great difficulty that the Commission might have to encounter was lack of unanimity in the profession, and so long as there was a feeling that general practitioner interests were not fully represented such unanimity would be all the more difficult to secure.

After some further discussion it was agreed that the Insurance Acts Committee be asked to nominate four general practitioners (three urban and one rural). On the suggestion of Dr. J. W. BONE, Dr. GREGG undertook to ask his committee to ensure that one of the nominees was from a colliery area.

Mr. SOMERVILLE HASTINGS said that it was important to represent ideas, not interests only, and therefore he asked for direct representation of the Socialist Medical Association. Dr. PETER MACDONALD, while having no special sympathy with the aims of that body so far as he knew them, thought it would be wise to accede to this request. Dr. J. M. MACKINTOSH thought the meeting was in danger of getting hopelessly entangled between representation and delegation. Mr. ZACHARY COPE suggested that the Commission had at least one very experienced and well-informed member of the Socialist Medical Association—Mr. Hastings himself. The Commission decided not to give special representation in this instance. Mr. G. F. GIBBERD pointed out that there were only three obstetricians and gynaecologists on the Commission, and urged an increased representation. The CHAIRMAN suggested that the proper course here was co-option on to the appropriate committees. Dr. DAVID WILSON urged the claims of the Association of British Ophthalmologists.

Dr. G. C. ANDERSON (Secretary) said that some members were looking at this matter from the wrong angle. The idea in appointing members to the Commission was to obtain a number of people who had some contributions to make to the problems in hand. With few exceptions they were chosen not because they happened to be representatives of a particular organization but because they were known by their writings or work to have something useful to offer. If now they started to form a commission composed of people who were there because they represented this or that organization they would get a body which in the end would not produce any report at all.

Dr. INGLIS CAMERON said that it was now clear that there were no delegates on the Commission, only a certain number of representatives, and others who were present in an individual capacity. He felt that we able better by

Mr. Souttar in a recent issue of the *Journal* went far to satisfy the critics, and if now a short statement could be published explaining a little more clearly—though not too precisely—the purpose of the Commission, the interpretation of its reference, and the status of its members in relation to the bodies appointing them it would complete the process of "disarmament."

Dr. S. WAND suggested that the question of representation of medical students and of members of the profession serving in the Forces might be considered. The CHAIRMAN thought that the views of these groups again might be most usefully elicited in the committees. The National Union of Students (British Medical Student Association) had already been asked by himself to submit a memorandum for the Commission at a later stage.

The Commission then agreed to the membership as originally set out[1], subject to the additions made—namely, a representative of the Medical Advisory Committee of the Nuffield Trust and four general practitioners to be nominated by the Insurance Acts Committee.

Scope of the Commission

Lord DAWSON OF PENN said that members of the Commission might be assisted if they perused again the report of the Consultative Committee on Medical and Allied Services, which was appointed by the Government after the last war to go into a good many of the questions which the new Commission would have to face. It was always a matter of pride to him as chairman that that committee reported unanimously. He thought the Commission should avoid trying to put up something brand new or something which aimed at too great completeness. The practice of medicine had been built up generation by generation, and it was only because medical knowledge had so far outstripped the organization of the practice of medicine that it was necessary for a body like this to pass the practice in review. In trying to plan so as to meet the needs of modern society with all its economic difficulties and at the same time to recognize the great growth of knowledge that had taken place, he thought they should bear in mind the "inevitability of gradualness." The most important question to settle was the regionalization of hospitals and health services. The practice of medicine in all its branches must become increasingly institutional, partly because of the growth of knowledge and the need for team work, also because the best that medicine could provide should be made available to every citizen. Some professions would be quite easy to plan for, but in medicine it was difficult because while planning the fabric they must preserve freedom of thought and initiative. It was not easy to apply collectivism to the fabric and yet maintain individualism in the human relationships. Another big question was the bridging of the gap between preventive and curative medicine. If these basic principles were settled first, all other things would be added unto them. He hoped the Commission would not attempt to issue a single report at a particular time, but rather to publish interim reports—no matter how many so long as they preserved a certain sequence. With regard to regionalization, which seemed to him the first problem to be tackled, it was well to remember that this was not new, it was dealt with by the Consultative Committee to which he had referred, but now it came forward with a certain urgency owing to the war. War did not so much create new problems as bring to the forefront problems which had been for long in the stage of incubation. Some most excellent work on this subject had already been done in Oxford under the auspices of the Nuffield Trust, and of this the Commission would take cognizance. The Commission must also address itself to the bridging of the gap between preventive and curative medicine so as to endeavour to present a united medicine to the student of the future. This fitted in with regionalization; and, this achieved, more than half the work of the Commission would be done. The work of the Commission would be carried out mainly in committees, which would have considerable freedom of action and would co-opt representatives, not of interests, but of different aspects of knowledge and experience. He suggested that to get a team in each committee it would be well to appoint nomination committees in the first instance. In conclusion Lord Dawson said that he liked to think of the medical profession filling its great place in the body politic. There was no profession which had widened in their generation to anything like the extent that medicine had done. The whole of the problems concerned with constructive health had really become part of medical thought in relatively recent years. They were not yet fully accepted, but it was largely because of their gradual acceptance that the Commission had been assembled to undertake a task of integration which he hoped would result in an even greater profession than the one they had had the honour of serving.

Sir FRANCIS FREMANTLE, M.P., said that there was much talk about revolution in the whole procedure of medicine, but he hoped the Commission in its public pronouncements would be on guard against revolutionary suggestions which would antagonize opinion in Parliament and in the country. The proposals they put forward should be based on the natural processes of growth. The question of medical auxiliaries, in particular the extension of the work of the district nurse, would he hoped be borne in mind.

Mr. SOMERVILLE HASTINGS felt that the Commission would want to know a great deal more about the conditions of general practice, hospital practice, and so on. The first thing to do was to bring their knowledge of conditions as they were right up to date. He appealed to members of the Commission to put away all preconceived ideas and to think only of the future of medicine and of the people of this country, without thought of sectional interests or individual interests or even of the interests of the profession as a whole.

Dr. G. F. BUCHAN thought that the first business of the Commission should be consolidation. It seemed to him that the two main subjects for consideration were general practice and hospital practice. General practitioners and public health practitioners had been unfortunately to some extent in conflict. The thing for the Commission to do in the first instance was to ascertain what common measure of agreement there might be, not to publish separate reports putting forward sectional points of view.

Procedure

On reassembling in the afternoon the Commission had before it certain suggestions for procedure. These were that there should be established five committees, dealing respectively with general practice, special practice, public health, hospitals, and the teaching hospitals, and a sixth, a Co-ordination Committee, which would integrate the reports of the others into one draft report. The five subject committees would meet separately (or jointly, when thought desirable) and consider the principles of medical organization or reorganization within their spheres, endeavouring to report progress to the Co-ordination Committee by the end of the year or as soon as possible thereafter. The draft reports of the Co-ordination Committee, before being approved by the Commission, would be submitted to the bodies represented thereon and to the profession generally and the comments and criticisms received would be considered by the Co-ordination Committee, which would then submit a draft report or reports to the Commission, with such criticisms and recommendations received as had not been included in the reports. Following this, the general principles having been laid down by the Commission, fresh committees would be set up to elaborate details of its policy.

Mr. BISHOP HARMAN urged that the sectional committees should be recommended to ask any representative medical organization concerned in that sphere of practice for the opinion of its members on general policy within that sphere and on such details as might arise. Many of the criticisms which had appeared in the *Journal* would be withdrawn if it were known that all groups of practitioners would be consulted on the particular matters with which they were concerned.

Dr. D. STARK MURRAY criticized the terms of reference for the proposed committees. Instead of considering the principles of organization and development in the five fields named, they might well concentrate on the discussion of domiciliary medical service, the prevention of disease, preservation of health, and treatment of the sick, allowing the consideration of special work to wait for the present.

Colonel R. G. GORDON thought that the work of the Commission might very well be done through a different set of committees from the ones proposed. Thus there might be committees concerned with domiciliary service, with hospital service, with out-patient clinics, with preventive medicine, with rehabilitation, with ancillary services, and with medical education.

[1] See *Supplement*, Jan. 4, 1941.

CLIMACTERIC SYNDROME RELIEVED

"High Doses of Oestrin are usually unnecessary, at any rate for the commoner menopausal symptoms—such as vasomotor disturbances—and consequently oestrin injections are, fortunately, seldom required. It has been my practice to begin with doses of about 500 I.U. daily by mouth. If this does not control the symptoms the dose is raised to 1,000 . . . this is usually completely effective. There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses . . . Pruritis, Kraurosis, Leukoplakia vulvæ, fall into this class and, provided sufficiently high doses are given, the results are little short of miraculous."

Dr. H. G DAIN said that there was some danger that the committees might start with different outlooks and bring to the Co-ordinating Committee work badly arranged from the point of view of the Commission as a whole. The better thing would be to establish the basic principles and ask the committees for their criticisms on these before they considered their own specific departments. Mr. WILFRID ADAMS suggested that some committee should consider not only the education of the profession but the education of the public in hygiene and an elementary knowledge of disease. Dr. H. H. MACWILLIAM said that from the Chairman's opening remarks it appeared that a future must be visualized in which 5% of the population would provide all the funds for private practice, and even this proportion might be still further diminished if the war went on for a very long time. The economics of the profession seemed to be a subject worthy of consideration by a committee. With regard to regionalization, a point that troubled him in the Nuffield Trust arrangements was that apparently they visualized an area from Anglesey to Carlisle with one key hospital in the centre. On these questions it seemed to him that the suggested procedure of the Commission was well adapted to get useful answers.

Mr. JOHN HUNTER, Dr. FRANK GAY, and Dr. O. C. CARTER supported the arrangement for committees as laid down in the original suggestions. Mr. SOMERVILLE HASTINGS said that the first thing to do was to make a survey, either as a Commission or through the committees, of the various fields. Medicine was not a science: its present position had been reached largely by a series of happy accidents. He did not think that basic principles could be immediately determined. They must be influenced in their deliberations by expediency, and the basic principles of organization had to come last of all. Their task was to arrange for an efficient service for the public, and it would be a mistake to try to pin that down to basic principles, as to which most of them had already preconceived ideas.

Dr. ANDERSON (Secretary) explained the idea behind the planning of the committees. The General Practice Committee, for example, would want to find out what was the state of general practice at the present moment, whether it should be linked up with some other agencies at work in isolation, and how to reconcile collective responsibility with individual freedom. Then the Co-ordinating Committee would come into being and would be able through the representations it received from these committees to lay down the basic principles to guide all concerned in the future consideration of the problems.

Dr. J. A. BROWN pointed out that certain basic principles had already been put forward in the Association's grey book, "A General Medical Service for the Nation."

The proposal to set up the five committees, together with a co-ordinating committee, was generally approved.

The Teaching Hospitals

Some discussion centred round the appointment of a Teaching Hospitals Committee.

Dr. S. WAND objected to the term "teaching hospitals," and wanted the committee to have as its reference "medical education, including postgraduate education and research." Dr. DAIN questioned whether it was right to exclude the teaching hospitals from the terms of reference of the Hospitals Committee. Apart from teaching, the work of those hospitals was the same as that of hospitals generally. Mr. SOMERVILLE HASTINGS hoped that at some time in the future all hospitals might be used for teaching, and that the Teaching Hospitals Committee, even if it retained its name, would in effect be a medical education committee. Prof. PICKEN said that this division of hospitals was quite irrational. Those who had been associated with the development of the municipal hospital knew that to an increasing extent it took part in teaching.

Sir ALFRED WEBB-JOHNSON thought that most of the objections to the separation of these two committees would be overcome if the Commission decided that the Hospitals Committee should consider all hospitals as within its province, including teaching hospitals. Nevertheless there were problems peculiar to the teaching hospitals.

Sir GIRLING BALL spoke to the same effect. The teaching hospitals were themselves very anxious to come into contact with other hospitals, especially municipal hospitals. Therefore he thought one committee could do the whole of the work as regards hospitals, except for the special problems relating to medical education.

It was then agreed that the words "excluding teaching hospitals" should be deleted from the terms of reference of the Hospitals Committee, which were to consider and report "on the principles of organization and development of hospitals, voluntary and council."

The terms of reference of the Teaching Hospitals Committee read: ". . . the principles of organization and development of teaching hospitals," and Mr. HASTINGS moved to substitute the words "the teaching of medicine." Mr. HUNTER thought that this would open up a wide issue, nothing less than the whole of the medical curriculum. Sir A. WEBB-JOHNSON pointed out that the original terms of reference did not exclude clinical teaching, whereas the terms which Mr Hastings proposed excluded the teaching hospitals. The CHAIRMAN suggested the words "hospitals engaged in undergraduate and postgraduate education," but Mr. HASTINGS was still not satisfied, saying that he was not convinced that teaching must always be within the walls of a hospital. He would not rule out the possibility of some medical education being undertaken by general practitioners.

Eventually Sir ALFRED WEBB-JOHNSON moved, and Sir GIRLING BALL seconded, that the reference should be: ". . . on the principles of organization and development of the teaching hospitals and clinical education." Mr HASTINGS said that this satisfied him, and the amendment was approved by the Commission.

Appointment of Committees

Certain nominations for each of the committees were then agreed to. The nominations were so arranged that each committee contained a majority of those with a direct interest in the subject of the reference and a minority of practitioners not so directly interested. The Co-ordination Committee was created to consist of the Chairman of the Commission the Chairmen of the five subject committees, and three members appointed by each of those committees.

A brief discussion took place on the powers of the committees to co-opt additional members from outside and it was agreed that each committee should have the power to co-opt two members, but that the Chairman of the Commission should have power to authorize the co-option of four members in all if he regarded it as necessary.

Colonel GORDON mentioned the desirability of eliciting the views of members in the Services. He suggested that when draft reports from the Co-ordinating Committee were about to be presented some member should go preferably to each Home Command, and there, at the central hospital, it would not be difficult to get a large number of medical officers from surrounding hospitals to attend, and they would be able to express their opinions and air any grievances.

The CHAIRMAN said that this valuable suggestion would be noted. He thought the proposal made earlier by Mr. Bishop Harman concerning the eliciting of opinions from representative medical organizations had been met by the proposal to issue draft interim reports and by the arrangements for securing adequate representation by co-option and otherwise of the views of groups and bodies not represented on the committees, and in particular practitioners on service. The question of increased representation of obstetricians and gynecologists to which Mr. Gibberd had referred had better be left to the committees themselves.

This concluded the business of the first meeting.

Speaking at the annual meeting of the Cremation Society, Lord Horder (the new president) said that the first great war created an increased interest in cremation, and it was safe to prophesy that the second great war will take that increased interest still further. For the first time in its history cremation was being placed on an equal footing with earth burial. Many local authorities were reducing their fees in cases of air-raid victims. The society's annual report showed a record increase of 2%, in the number of cremations carried out in Great Britain during 1940—25,175, compared with 19,813 in 1939 and 11,280 in 1936. The number of crematoria had increased from thirty-three in 1939 to fifty-six in 1940.

BLAST PROTECTION FOR HOSPITAL WINDOWS

Air raids are increasing in their intensity; the weight and destructive capacity of bombs are greater, and hospitals are more likely to be put out of action even from a "near-miss." Experience has shown the need for bricking up the windows of resuscitation wards. It is not only that destruction of windows and black-out material raises difficult problems of lighting, but the temperature of the ward may fall so seriously as to endanger the patients from that cause alone. Arguments for occluding the window-openings apply to theatres too; and, with somewhat less force, to general wards, where bricked-up windows mean difficulties of ventilation and serious interference with the patients' comfort.

If the principles of "switching," to which reference has recently been made, are understood and acted upon, the number of casualties admitted to any one hospital during a heavy raid will not usually be great, and possibly a good plan would be to have "safe" accommodation in the larger central hospitals for, say, 100 patients. When not required for casualties, wards are frequently used for general hospital purposes, and it might be well to brick up two windows out of three in such wards, the third window having bricks only to a height of, say, 6 ft. or 6 ft. 6 in. from the sill-level. If the top part of these windows should go it will be necessary, to make the black-out effective, to have portable screens ready to put quickly in place. Unless something of this sort is done, the wards will really not be habitable or usable for dual purposes. There will still be danger from flying glass, but there do not appear to have been many injuries from this source in wards with unprotected windows. In wards where patients stay for two or three weeks loss of sunlight is a serious deterrent to recovery, but in a resuscitation ward, where the usual stay is a matter of hours, it is not so important.

Every hospital should have one theatre with blocked-up windows unless there is an underground theatre or one so situated inside the building that it is not subject to blast. In the present state of the labour market it would be idle to ask for the bricking-up of all windows in hospitals in vulnerable or specified areas, but there is a recognized machinery for obtaining help in matters of both labour and supply of materials. It is unfortunate that comparatively few members of the profession fully understand the Regional organization of the Ministry of Health, which provides that machinery. It is based upon the Civil Defence Regions, in each of which there is a Commissioner, who, in the event of the isolation of his region, becomes what might be called "viceroy." At his headquarters he has a staff of officers of the Ministry of Home Security, with a Senior Regional Officer (S.R.O.) in charge. The Ministry of Health has a regional headquarters staff in a near-by building in the charge of its own S.R.O. Between the two Ministerial headquarters there is a liaison which is closer in some Regions than in others. Approach to the S.R.O. of the Ministry of Health for E.M.S. purposes by all medical officers of health or superintendents of hospitals is through the Hospital Officer of the Region, who may be reached directly or through the Group Officer. In Region V (London) the Sector Group Officers have the status of Hospital Officers and have, like Hospital Officers, direct access to the Director-General.

A great deal of authority has been delegated by the Ministry of Health to its Senior Regional Officers so that there may be no delay in putting in hand urgent work which complies with the requirements of settled policy. Moreover, representations made to Regional Officers are transmitted to the Ministry and receive consideration in modifications of policy which changing conditions may dictate.

A proposal, such as that to brick up windows, should be put through the Hospital Officer to the S.R.O., who, if he approves, will authorize expenditure (ranking for grant) and do his best to facilitate and expedite "supply" of both material and labour. All work entailing expenditure of money, labour, or materials should be put forward with a reasoned statement of its necessity and urgency to the S.R.O. He, within limits, has power to put matters in hand at once, and in very many cases can do so without reference to Whitehall.

Local News

ENGLAND AND WALES

The Westminster Hospital Carries On

A heroic story can now be told of the new Westminster Hospital at Millbank. This hospital received direct hits; the most serious blew out all the windows and cracked or broke down many walls and partitions. But the hospital never ceased to function. The out-patient departments reopened within a week, and within three weeks had a daily attendance of 400 patients. Within a week also 50 beds were again available in the wards, within a fortnight 169 beds, and within three weeks 292, which is to be the maximum for the next three months at least, as compared with 256 before the raid. One side of the hospital was put out of action and has been sealed off; a single wall now divides the normal hospital activities from a ruined building. When the bomb struck Westminster Hospital an operation had just been completed, but in spite of the fact that the four occupants of the theatre were buried knee-deep in debris only a slight scratch was received by one of them. On the night of the occurrence bad casualties had to be admitted to the wards, and some were treated at the first-aid post attached to the hospital. During the raid all the patients in the wards were evacuated to the basement by the staff; this took place while fires were raging around the hospital and one on the fourth floor of the hospital itself. A basement room was quickly fitted up as a theatre, and casualties were attended during the whole of the time. Dr. O'Brien, representative of the Rockefeller Trust, was present and afterwards sent a letter to the Minister of Health praising in the highest terms the courage and skill shown by all concerned in dealing with a frightful situation, also mentioning the complete lack of panic or hysteria among the patients themselves, thanks to the matter-of-fact behaviour of the staff. Westminster Hospital has an arrangement with the Surrey County Council whereby 25 beds have been opened in Surrey, the hospital providing complete equipment and staff. Six medical students are in residence there; others are obtaining clinical instruction at hospitals elsewhere in the sector.

St. Bartholomew's Under Fire

Of the eight hundred years which St. Bartholomew's has seen, 1940 was surely the most exciting. The treasurer's report, usually a pedestrian document, tells a heroic story. The hospital has been hit several times during aerial bombardments, but without very serious damage. In September a high-explosive bomb fell immediately outside the nurses' home without causing casualties, and later in the same month a bomb fell on the anatomical lecture theatre and its annexes, which were completely demolished, but the buildings were unoccupied. More recently a bomb fell through the roof and floor of the operating theatre in the casualty block, but did not explode, and the damage, though substantial, was only a fraction of what would have been caused had it done so. On the night of December 29, when thousands of incendiary bombs were dropped on the City of London and very large fires were started, the hospital was for a time deprived of its supply of water, gas, and one circuit of electricity, and it was receiving air-raid casualties, of which nearly one-half had to be kept in the wards. At about ten o'clock that night the police warned the hospital that the fire brigade was finding difficulty in checking the flames, and that it might be necessary to order complete evacuation at very short notice. As the lifts were out of action it was decided to begin immediately to evacuate 102 of the 223 patients in hospital. These patients were carried on stretchers down the stairs, loaded in motor coaches, and taken without mishap to a sector hospital, all within two hours. On numerous other occasions the hospital has found itself the centre of an area which appeared to be the enemy's main objective, and the treasurer, on behalf of the governors, expresses his profound admiration "of the loyal, devoted, and courageous manner in which they conducted themselves on all occasions. . . . The medical staff, aided nobly by the students and members of the lay staff, have given of their best, and all I need say is that Bart's expected of them no less." Every roof of the hospital has been fitted with fire-

fighting appliances, and six regular fire squads are on duty every night.

The income of Bart's in 1940 (£203,000) is down by £12,000 on the year. There has been a large diminution of income through loss of rentals of hospital property owing to enemy bombing. The daily average number of patients in hospital was 137, and the average duration of stay just under ten days. The first attendances of out-patients numbered 12,680, as compared with 21,790 in 1939, and the first attendances of casualty patients just upon 42,000.

Correspondence

Treatment of Burns

SIR,—Mr. Rainsford Mowlem (May 3, p. 686) raises a most interesting point in the last sentence of his letter on the treatment of burns. He says that he hopes that in the near future only innocuous substances will be issued to first-aid posts, etc. I heartily agree. So often one finds that a burn has been sent up to hospital covered with one of the excellent coagulant jellies applied by someone who is not qualified to use them. When such a case arrives, it is very hard to see the extent of the burn, and often it is not until the patient is in the theatre that one finds out just how bad the burn is.

Surely the most important thing in dealing with burns is the cleansing of the burn under an anaesthetic in the operating theatre, and for first-aid work a compress of sodii bicarb. is all that is required to allay the pain of the burn. When the patient arrives in the hospital this can easily be removed without sticking, and the burn can then be correctly examined. Would that the first-aid workers will remember this. —I am, etc.,

Royal West Sussex Hospital, May 5. JOHN GORDON.

Subcutaneous Ligature of Varicose Veins

SIR,—I was interested in Dr. H. S. Russell's article (April 26, p. 626). He realizes that something more than mere injection of large internal saphenous veins is necessary if occlusion and permanent or semi-permanent results are to be obtained. I quite agree that the trend of the most modern treatment of varicose veins has swung back from pure injection to a combination of ligature-injection—even better, to excision of a portion of the internal saphenous vein. The last-mentioned is really the only guarantee against recanalization. But I also agree that his excision lifts the treatment out of the hands of capable general practitioners merely for want of an operating theatre and an assistant.

Now Dr. Russell's method of the insertion of a perineum needle right through skin, subcutaneous tissue, and varicose vein seems to me to be rather a crude procedure which is adopted merely because the refinements of an operating theatre are denied to the average G.P. and to the vast majority of his patients; he could secure the theatre in a nursing home for his richer patients. I have always maintained (and been able to substantiate it in my large varicose vein clinic) that even the largest "drain pipes" can be occluded provided that: (1) An empty vein technique is employed—pneumatic tourniquet. (2) A sufficiently strong sclerosing solution is used—e.g., lithium salicylate 35% with 1% ethocaine, and quinine with urethane injected from separate syringes, preferably quickly through the same large-bored needle. (3) And, above all, that the vein is subsequently tightly compressed, so that the sides of its walls are kept in apposition for two to three days after the injection by firm compression with elastoplast. This is done by covering the injection site with collodion and either a firm wad of wool or about two inches of elastoplast rolled up into the form of a "cigarette," which is laid over the course of the vein; then elastoplast is applied, and the side flesh is drawn towards and over the "cigarette," and flesh from the other side is approximated so that not only the rolled elastoplast ("cigarette") but the flesh from the sides itself compresses the vein. *This strapping is left on for three days.*

With this procedure recanalization is rare. I am sure that with this procedure recanalization is not more likely than after the method described by Dr. Russell. Moreover, the injection method, followed by tight compression, is far less painful for the patient than Dr. Russell's method.

Another criticism of his method is that it opens the way to sepsis. In the treatment of 10,000 patients I have not yet had any case of sepsis following an injection.—I am, etc.,

Liverpool, May 2. STUART MCAUSLAND.

Abdominal Symptoms after taking Opium

SIR,—The correspondence in the *Journals* of February 8 (p. 215), March 22 (p. 461), and May 3 (p. 688) on abdominal pain after opium administration prompts me to write, but I have selected the title "abdominal symptoms" rather than "abdominal pain" to stress the possibility of severe vomiting where opium has been prescribed.

Mr. H. P. Winsbury-White (p. 461) quotes Sir Lauder Brunton's book as saying that opium stimulates intestinal peristalsis in some cases. I believe that the account of the action of opium in Hale White's *Materia Medica* (1935, p. 297) best explains the abdominal complications met with in practice. "Opium produces great loss of gastric tone, often spastic contraction of the pylorus, and inhibition of normal peristalsis in the stomach. Its emptying is delayed. In the small gut peristalsis and tone are increased. In the colon tone is often so great as to produce spasticity, and therefore further delay in the passage of food." A consideration of this description explains the sickness which may occasionally be so prolonged as to cause anxiety in seriously ill patients.

Personal experience leads me to believe that pain when it occurs is due to spasm of the pylorus. I have taken omnopon in a moderate dose, by mouth, twice in my life, and have only suffered from really severe epigastric pain twice in my life. (Only because a double experience rules out the possibility of the pain having been coincidental do I admit publicly to having been so inept as to take part in the second experiment. The truth of the matter is that I had forgotten all about the first experience.)

On each occasion I was awakened after about one and a half hours by very severe epigastric pain without pain in the hypochondrium. On the first occasion the pain was accompanied by sickness, but vomiting relieved it quite quickly. On the second occasion the pain was much more severe, and felt as it it might have been due to perforation of an ulcer. There was no sickness, but profuse sweating and a feeling of cold. After the pain had lasted perhaps ten to fifteen minutes without abating, several tablets of traesentin (an intestinal antispasmodic of complex formula) were tried. The pain was quickly and completely relieved, and sleep followed in a few minutes, but was disturbed again an hour later by another slighter attack of epigastric pain, which went very quickly after more traesentin. This drug was used because it was to hand, but atropine would appear to be a reasonable drug to use, as Mr Winsbury-White suggests.—I am, etc.,

Norwich, May 5. STEPHEN FALLA.

Frostbite

SIR,—In a letter by Dr. Raymond Greene (October 5, 1940, p. 469) it was pointed out that in the treatment of frostbite friction of any kind is dangerous. My experience treating a number of minor cases—ears and hands—confirms this; and I found the simplest methods satisfactory.

To avoid infection blisters were left intact and painted with a 1 in 1,000 solution of acridavine. They were then dusted with antiseptic powder and covered with cotton-wool. Over the wool the men wore woollen gloves and Balaclava helmets. Every case responded rapidly, without sepsis. The fluid in the blisters was absorbed within two or three days, leaving dry scales which peeled off, exposing healthy skin. No friction was used, and the only thermal treatment was the prevention of heat loss described.

I had the interest of watching my own recovery under this simple treatment. One finger was swollen, cherry-red, and painful, but numbed to pinprick, cotton-wool touch and light pressure. The skin was not blistered, although tense and devitalized. After a few days the skin on the tip cracked and I began to peel. Immediately I had removed a small piece of dead skin sensitiveness returned, not only in the area thus uncovered, but throughout the whole finger. I could then detect cotton-wool touch and pinpricks in the areas still covered by devitalized skin. This immediate recovery was nearly but not quite complete. Full recovery occurred gradually in the proximal segment first, and reached the tip about a fortnight from the time of injury.

I deduce that increased tension in the finger, and not any histological damage to the nerve endings, is the main cause of loss of sensation. As I have no book with me at sea which discusses this point I can—until I am contradicted—amuse myself with the idea that this observation is original.—I am, etc.,

M. C. ANDREWS,
April 15. Surgeon Lieut.-Commander, R.N.V.R.

Ergotoxine in Shock

SIR,—With reference to the article on recent air-raid casualties by Dr. Margaret Ball and Mr. George Quist (February 22, p. 273), in which they report that "the results of the treatment of severe shock by replacement of fluid with blood and plasma were disappointing," I beg to suggest the trial, as an additional measure, of intramuscular injections of ergotoxine aethanosulphate 1/120 to 1/60 grain in this condition. Since these doses are regularly used in obstetric practice and in the treatment of migraine they may be employed without fear.

Ergotoxine is an inhibitor of sympathetic overactivity, and has been successfully used by Hassan and Mahommed (*Lancet*, 1940, 1, 1001) as an antidote to scorpion toxin, part of which is a strong stimulant of the sympathetic nervous system. Since we have no recognized drug at present with which to combat shock, the trial of ergotoxine in therapeutic doses in this condition is fully justified.—I am, etc.,

Capetown, April 6. J. WALKER TOMB, M.D.

Whither Welfare?

SIR,—The article on "Whither Welfare?" (May 10, p. 719) deserves most careful attention. The argument of Dr. Cicely Williams that more can be done to prevent disease than by any other method through the sensible teaching of home hygiene and right diet is put forward most convincingly and cannot be gainsaid. The practitioner treats disease but does not prevent it, and the medical research worker seeks for methods for immunization against or cure of disease, but the well-trained welfare worker, by teaching in the home, goes to the root of the whole matter, and, adequately supported, can stop disease appearing. How little the Medical Research Council realized this was shown by the fact that after my retirement it abolished the Department of Applied Physiology at the National Institute of Medical Research.—I am, etc.,

Chalfont St. Peter, May 11. LEONARD HILL.

New British Summer Time: A Criticism

SIR,—May I inquire whether certain disadvantages of the new summer time have been sufficiently considered from the medical standpoint? Speaking for my own district (the North-West), when any large-scale aerial attack has been made the alert has usually been sounded about one hour after black-out time, and I find that most people who do not regularly sleep in shelters have been in the habit of waiting up until this "danger" time has passed before retiring. If we consider the week before the advent of the new system we find that people were retiring about 10.30 p.m.; to-day we find that they are waiting up until 11.30 p.m. or midnight before they consider it safe to retire, and before the longest day arrives the "safe" time will be 12.30 to 1 a.m. So that, even if no raid develops, large masses of the population are missing a substantial proportion of their sleep; in the event of a raid the position is worse, since when the raiders depart (at present 4 a.m. to 4.30 a.m.) these people are left with only three to three and a half hours sleep.

Under the original British Summer Time these people would have retired one hour earlier, and after a long raid would have had an extra hour in which to sleep. I would go even further and suggest that it would be better to have turned the clock one hour backwards to G.M.T. (since the visitations of the Luftwaffe are independent of our own chronometric manipulations). This would time the raids to begin and end earlier, with obvious sleep-saving advantages at either end. From this point of view I venture the opinion that any advantages offered by the new British Summer Time are more than counterbalanced by the impairment of working efficiency through the needless loss of sleep it entails.—I am, etc.,

May 9. LESLIE BALLON.

Universities and Colleges

UNIVERSITY OF SHEFFIELD

The University Council made the following appointments on May 9: *Assistant Lecturer in Mental Diseases*: F. J. S. Esher, M.B., Ch.B., D.P.M. *Junior Demonstrator in Anatomy*: M. Laird, M.B., Ch.B. *Part-time Demonstrator in Anatomy*: Mrs. Mildred John, M.R.C.S., L.R.C.P.

The Council accepted the resignation of Dr. F. E. E. Schneider of the post of assistant lecturer in mental diseases with regret and thanked him for his services to the University.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a meeting of the Council of the Royal College of Surgeons of England, held on May 8, with Sir Hugh Lett, President, in the chair, Mr. J. W. Walker and Mr. T. Harrison Butler were admitted to the Fellowship.

Mr. John Basil Hume was elected a Member of the Court of Examiners.

It was decided that the amount of the Cartwright Prize should be increased from £85 to £100.

The President was appointed, *ex officio*, a member of the Governing Body of the British Postgraduate Medical School for one year.

Diplomas

Diplomas of Membership were granted to the 171 successful candidates named in the report of the meeting of the Royal College of Physicians of London, published in the *Journal* of May 3 (p. 694) and to the following:—

N. Alders, V. R. Arulanandom, J. L. Ballantyne, P. L. N. Bay, M. Bates, R. I. S. Bayliss, A. B. Black, E. M. Cheffins, D. R. Christie, Doris Critchley, Aileen M. Dickins, A. Fessler, J. H. Fodden, H. A. Hashemian, M. Hewitt, M. H. W. Holloway, J. S. Johnstone, Anne E. E. Jordan, J. M. Joshua, H. H. Kennedy, A. Klidjian, Padma Kumar, K. R. Llewellin, T. P. Mann, J. H. G. Morris, M. Roth, Melicent E. Salmon, J. M. W. Sedgwick, Eleanor M. Singer, C. C. K. Smith, J. G. Stubbs, H. Williams, J. A. Williams, Jean K. M. C. Wilson, R. B. Zachary.

Medical Notes in Parliament

Milk Certificates

Mr. GROVES contended on May 7 that the form of certificate for additional supplies of milk to persons suffering from certain diseases was objectionable, in that a doctor was required to certify the precise disease from which the person in need of the additional supply of milk was suffering, and that the certificate had to be handed to the local dairyman, thereby making him and also his employees aware of information which should be strictly confidential. Major LLOYD-GEORGE said the views of the British Medical Association on this procedure had recently been received and were under consideration.

Alien Doctors in Pioneer Corps.—Mr. ERNEST BROWN told Mr. George Strauss on May 8 that the services of alien doctors in the Pioneer Corps were considered for employment in hospitals and institutions equally with others of allied or enemy nationality through the machinery set up by the Central Medical War Committee. Capt. Margesson had given instructions that every facility was to be afforded for their attendance at interviews with employing authorities and for their discharge from the Corps when employment was obtained.

Civil Nursing Reserve Call-up.—On May 8 Mr. GEORGE STRAUSS, in view of the shortage of trained nurses, asked what was the policy of the Government in calling up for service those who have registered their names, at the outbreak of war, on the Civil Nursing Reserve. Mr. BROWN replied that to utilize the services of any trained nurse member of the Civil Nursing Reserve not already in employment he had recently extended the scope of the Reserve to cover almost every type of hospital, including certain special hospitals where the shortage of nurses was acute. Where a trained nurse offers whole-time service without reservation as to place regional Nursing Officers could ordinarily post her without difficulty. This could not always be arranged, however, where the member's offer was restricted either to part-time service or to service in a particular locality or in some other way. Such members were now being approached and asked to offer service not subject to these limitations. The use to be made of their services would depend on the replies.

The Services

R.A.F. AWARDS

The George Medal has been awarded to Flying Officer Richard Garwood Robinson, R.A.F.V.R., and to Corporal John Taylor, R.A.F. The announcement of the awards in a *Supplement* to the *London Gazette* dated May 5, 1941, said: "One day in February, 1941, an aircraft crashed just beyond the boundary of an aerodrome. Flying Officer Robinson, medical officer at the station, was at the scene of the accident almost immediately, and was first seen crawling through heavy smoke and fumes, but when he had nearly reached the wreckage he was forced back owing to an explosion of one of the main petrol tanks. Undeterred, however, he returned to the seat of the fire, which was around the pilot's cockpit, where he was joined by Corporal Taylor, who had been playing football and had run to the crash clad only in his football attire. Together they attempted to extricate the only remaining member of the aircraft. To assist them in their efforts a foam apparatus was turned directly on them. Although petrol and oil tanks, ammunition, and verey lights were exploding Flying Officer Robinson and Corporal Taylor persisted in their efforts, and finally extricated the body. Both displayed great courage and a complete disregard for their own safety, and although both suffered from the effects of the foam sprayed on them it undoubtedly saved them from being gravely burned. On a previous occasion Flying Officer Robinson displayed the greatest courage in attempting to rescue the members of a burning aircraft, in spite of exploding bombs and ammunition."

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Prisoner of War

Temporary Lieut.-Colonel John Chiene Mackay, M.C., T.D.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

Measles was the only common infectious disease, with an increase of 921 cases, which showed any considerable variation from the number of notifications of the previous week. The counties with an increased incidence were generally distributed over the country. The outstanding rise occurred in Birmingham C.B., where the number of cases notified went from 411 to 586. The greatest decrease was in Northamptonshire, where the notifications were one-third of those of the preceding week. There were 24 fewer notifications of whooping-cough in England and Wales. In Scotland there was also a fall in the incidence of whooping-cough. Glasgow accounted for 150 of the 219 cases.

Although the rise in the number of cases of scarlet fever was only 33 for the whole of England and Wales, almost half of the counties reported increases. In Middlesex notifications rose from 19 to 60, and in Essex from 34 to 50.

The number of notifications of diphtheria during the week did not vary greatly in the individual counties, compared with the preceding week. It has been more prevalent in the North Country than in the South.

Cerebrospinal fever, after the fall in notifications during the previous week, returned to the level around which it had been fluctuating since the week ending March 15. The increase of 44 cases was made up mainly of isolated cases spread over the country, but multiple cases were reported from areas that had no cases in the preceding week. The chief of these districts were Durham, South Shields C.B. 5, Bishop Auckland U.D. 4; Yorkshire, East Riding, Kingston-upon-Hull C.B. 7.

The epidemic of dysentery in Hemel Hempstead M.B., Herts, is decreasing: 30 fresh cases were reported in the whole county during the week as compared with 50 in the preceding week. The largest increases were from Lancashire, Lancaster M.B., where notifications rose from 1 to 12, and Surrey, Coulsdon and Purley U.D., from 0 to 14. Dysentery reappeared in Essex, Colchester M.B., after a lapse of one week; 4 cases were notified in this area, which recently had a severe outbreak. The number of cases in Lancashire, Whiston R.D., where an outbreak has lasted over two months, increased from 5 to 11.

No. 15

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 19.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Medical News

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., on Tuesday, May 27, at 2.30 p.m., when Dr. H. M. Hanschell will give an address on "Venereal Buboes."

Field-Marshal Sir Philip Chetwode, on behalf of the War Organization of the Red Cross and St. John, is opening this week the first convalescent hospital for civil defence workers. This hospital, in Buckinghamshire, was planned by Lord Horder and Mrs. Joan Woollcombe. It accommodates twenty-five beds for men and twenty-five for women, and the cases admitted will include ailments as well as shock and wounds. Its main purpose is to restore A.R.P. workers to health after illness. Patients will be selected through the country hospitality scheme, which continues to act as an independent body within the machinery of the Red Cross War Organization.

At the annual general meeting of the North of England Ophthalmological Society, held at Sheffield, Mr. H. Haward Bywater of Liverpool was elected president and Mr. Percival J. Hay of Sheffield secretary.

The Palestine Conference of Jewish Physicians was recently held in Tel-Aviv, when Arab, English, and military physicians were among the thousand delegates. The conference was greeted by representatives of the Government, the Municipality, and Jewish institutions. The discussions were mainly devoted to diseases of the blood.

A new division of chemotherapy has been formed in the National Institute of Health of the United States Public Health Service to be under the direction of Dr. William H. Sebrell, jun. The new unit will be concerned with research on sulphanilamide products, and with new synthetic drugs with anti-malarial properties, in order to make the United States independent from the Dutch East Indies supply of quinine. The division will have quarters at the National Institute of Health in Bethesda, Maryland. The building will also be the headquarters of the divisions of chemistry and zoology.

Dr. C. L. Herman, who died at Wynberg, Cape Colony, in August, aged 81, bequeathed £40,000 to the medical faculty of Capetown University for research work.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

LETTERS, NOTES, ETC.

Chemotherapy in Otitis Media

DR. L. B. SURTON (Surbiton) writes: I was interested to read the article on chemotherapy in acute otitis media by Dr. J. B. Jessiman (March 15, p. 399). Before the use of chemotherapy in acute otitis media the results of previous treatment, with local application, drops, etc., were slow and obscure, and one was inclined to send such cases more frequently for consultation to hospitals for fear of complications, such as mastoiditis, etc. But with the advance of chemotherapy complications seem to have diminished. For the last eighteen months or so about nineteen cases of acute otitis media, ranging from children to adults, were treated at home with sulphapyridine with favourable results, and only one child, aged 2 years, was sent to hospital after three days' treatment—for fear of mastoiditis. This patient was kept at hospital and continued with sulphapyridine with good results and recovery. I have been using rather smaller doses of sulphapyridine than Dr. Jessiman reports, and I think I shall increase the dose in future. However, in most cases of acute otitis media, as soon as chemotherapy is started, there is evidence of improvement by the next day, in the lowering of the fever, less pain and discomfort, and on inspection a gradual resolution of the inflammation, congestion, and the bulging of the drum or disappearance of vesicles on drum. Sometimes the "bulging" will burst and the discharge of pus will clear up in about fourteen days or so. I always order to be instilled in the ear, after the pus is cleared out, guttae glyc. ac. bor., and the application of some form of heat—in adults the ear over a jug of hot water for steam. Recently an adult aged 50 developed bilateral otitis media after a mild attack of tonsillitis. Sulphapyridine tablets were given and temperature went down next day. The left drum developed a small perforation which healed in about a week. The right drum took rather longer to clear up. I have not treated many cases of chronic otitis media, but in the few cases where chemotherapy was employed benefit was seen. I am now intending to try on some chronic otitis media cases with old standing discharges the principle of the present-day treatment of war injuries—that is, packing the ear canal with powdered sulphapyridine; and from the results obtained in packing some septic ulcerated legs it seems probable that benefit will follow.

Antiseptic Snuffs

DR. F. G. CAWSTON writes from Durban: Cleansing of the naso-pharynx with warm saline immediately relieves a sore throat, but most popular remedies are irritating to the mucosa and both lotions and oils may be unduly retained, so that further use of powders is indicated. Investigations with antiseptic snuffs, as reported in the *Journal* of February 1 (p. 145), are of great interest. It is, however, probable that some sulphanilamide compound may have to be taken orally to cure a deep-seated sinusitis associated with recurring colds (and causing tinnitus and deafness) and this may well be combined with appropriate vitamins.

The War and Opium

The twenty-fourth report of the Advisory Committee of the League of Nations on Traffic in Opium made last year to the Council drew attention to the possible repercussions of the war on national and international supervision of narcotic drugs in accordance with the Conventions, and on the activities of the committee. It stressed the "bitter lesson of experience" in the last war with the marked recrudescence of drug addiction and of illicit traffic. A resolution was adopted urging on the Governments concerned the imperative need for continuing, without relaxation, the international duties undertaken by the contracting parties. The instruction to the committee by the Council and the Assembly to convene a conference on the limitation of the cultivation of the poppy and the production of opium remains unfortunately in suspense, although the appointment of a new assessor (Mr. W. Gaskell) to prepare the work for this conference is announced. Reviewing the completed returns for 1938 of the world traffic in narcotics, the Advisory Committee concludes "that the world manufacture and consumption of the five principal drugs correspond to its legitimate requirements." These are, for the year: 42.7 tons of morphine, 611 kilos of heroin, 27.5 tons of codeine, 2.5 tons of dionine, and 3.8 tons of cocaine.

The Salvation Army's War Work

The red shield bearing the name of the Salvation Army has become a well-known emblem in every part of the present "battlefield." The principle on which this great voluntary organization is working is to go where the need is greatest. One of the principal features of its war work is the provision of mobile canteens. In the early part of the war a fleet of these operated among the Expeditionary Force in France. Since Dunkirk they have been at work in this country among Service men and also among civilian sufferers. Thus the announcement of the raiding of Coventry was accompanied by the statement that the first relief organization to arrive in the city after the bombardment was the Salvation Army with its mobile canteens. At the larger shelters in London and elsewhere the Salvation Army is one of the most conspicuous of the voluntary bodies distributing food at night and in the early morning. In an illustrated booklet which reaches us, describing the service on many fronts, it is related that in the early nights of the raiding a young woman officer of the Salvation Army offered to set up a first-aid post in a London tube shelter, but her proposal was coldly received by the stationmaster, who said that if she cared to mix with the crowd she was at liberty to do so. The opportunity soon came for her to give first aid to a confinement case and to a case of acute appendicitis, and to accompany both cases in the ambulance to hospital, with the result that the stationmaster asked her to carry out her original suggestion, and himself fitted up an ample space as a first aid post.

Owing to the increasingly severe restriction on paper the Annual Report of Council, as adopted by the Council on April 23, has been shortened for publication, and for the same reason the Financial Statement appears in abbreviated form.

PRELIMINARY

1. Inevitably the continuance of the war has of necessity curtailed many of the Association's normal activities, both central and local. But every effort has been made, with the help of Chairmen of Committees and, in some cases, Executives of the Committees to safeguard the interests of the profession.

2. THE ROLL OF HONOUR includes the names of twenty-seven medical officers killed on active service, eighteen officers who died on active service, and seventeen civilian members, four of them medical women, killed through enemy action. The Association also has to deplore the loss of 333 other members.

3. The membership of the Association at the end of March, 1941, was, notwithstanding war conditions, 39,466.

4. In the belief that national post-war reconstruction will involve profound changes in medical practice the Council, in co-operation with the English Royal Colleges and the Scottish Corporations, has set up a Medical Planning Commission to study wartime developments and their effects on the country's medical services both present and future. The Commission will hold its first meeting very shortly.

5. The Sir Charles Hastings Clinical Prize for 1941 has been awarded to Dr. E. P. Edmonds (Aylesford). The Council has decided that the Sir Charles Hastings Clinical Prize, the Katherine Bishop Harman Prize, the Middlemore Prize, the Stewart Prize, and the Association's Scholarships and Grants shall not be awarded during the remainder of the period of the present emergency.

6. The Council is discussing with the Ministry of Health the advisability of providing further instruction for the medical profession in the treatment of gas casualties.

7. The Council has been instrumental in forming a Medical War Relief Fund with the object of assisting, by way of loans or grant, practitioners who are in difficulty or distress in consequence of damage by enemy action to their surgeries and equipment. A full report of the working of the Fund was published in the *British Medical Journal* for April 12, 1941, page 566.

FINANCE

8. The accounts for the year ending December 31, 1940, the first full year under war conditions, show the continuing sound financial position of the Association.

Balance Sheet

Provision for war risks insurance has been made and the various reserve funds have been maintained at a high level. Since the close of the financial period steps have been taken to increase the sinking fund insurance policies on the leasehold premises of the Association by £100,000. A General Contingency Reserve has been established to provide for increased taxation, additional war damage contingencies, commitments for extension of premises, and other unusual expenditure.

The amounts certified by the architect and paid to the contractors for the erection of the new extensions totalled £126,227. This year a further sum of £13,100 has been paid to the contractors. Any further immediate liability is limited to the cost of partitioning and decoration carried out for incoming tenants. £5,000 has been written off the Extension of Premises Account for depreciation.

The remaining investments in stocks were sold during the year to meet some part of the cost of the building extensions, showing a profit of £2,264, which has been added to the Surplus Account. The Reserve against Commitments for Extension of Premises represented by certain of these investments has therefore been added back to the Surplus Account, which, on December 31, 1940, totalled £319,650.

The value of the stock of *Journal* paper held at the end of the year was £5,398. This is considerably larger than usual because of the substantial increase in the cost of paper. In order to meet any emergency, the Journal Board has purchased the full ration of paper allowed by the Ministry of Supply.

Income and Expenditure Account

Despite the reduced subscription now enjoyed by an increased number of "Service" members and a further increase in the free list of members of over fifty years' standing, the revenue from subscriptions for the year increased by more than £500. Rents remained stationary.

Expenditure was diminished by £27,000. The War Damage Act requires the insurance of buildings against damage arising during the first two years of the war by the payment of a premium to be met in five annual instalments. It is estimated that the premium for the insurance of the buildings will amount to £6,000. There is provision in Part II of the Act for the compulsory insurance by the Board of Trade of movable plant, office furniture, and equipment against war damage during the same period; it is estimated that the premium will amount to £225.

"Journal" Account

In spite of severe restriction of the size of the *Journal* by the Ministry of Supply's control of paper, which reduced the space available for advertisements, the revenue from advertisements has been more than maintained owing to an increase of 50% in the rates for space made in May, 1940. Though many production costs have increased, particularly the cost of paper, these have been more than offset by the smaller *Journal*. More copies were printed, but the net cost of the *Journal* to the Association has been reduced to one-quarter of that of the previous year, a saving of £12,000.

Estimate of Receipts and Expenditure for 1941

Whilst it may be confidently assumed that the membership of the Association will be maintained during the year, there will be some diminution in the average rate of subscription

due to further increase in the number of members claiming the "Service" rate. This decrease will probably be more than offset by the increase in rents obtained from lettings in the new Northern extension. The revenue from investments will be reduced during the year. The income for 1941, therefore, is estimated to reach £106,000.

On the Expenditure side the policy of restricting the central activities of the Association must perforce be continued, with perhaps some relaxation. The important work of the Medical Planning Commission will begin in May. With a continuing rise in production costs it is too much to hope that the remarkably low cost of the *Journal* to members can be maintained. Increased taxation, including a further sum for War Risks Insurance beyond the amount set aside in the 1940 accounts, must be provided for.

Considering these factors, it seems likely that the total ordinary expenditure will reach £90,000, but it must be understood that this is an approximate figure which may be varied by changes in policy necessitated by war conditions. To this sum must be added at least £7,000 for depreciation of premises, library, and furniture, £3,500 to Sinking Fund for the redemption of leasehold premises, £1,500 for loss on exchange on Dominion currencies, £2,000 for dilapidations and redecorations, making a grand total of £103,500, and an estimated credit balance of £2,000.

CENTRAL MEDICAL WAR COMMITTEE

9. The Council has received the following Report of the work and activities of the Central Medical War Committee:

In its last Annual Report the Committee described the recommendations it had made on the subject of conscription and stated that its proposals had been accepted by the Government. The machinery evolved for the compulsory recruitment to H.M. Forces of practitioners within the registered age groups is working smoothly. The Committee has appointed a Services Committee to deal with the recruitment of individual practitioners to the medical branches of the Armed Forces; to consider recommendations of Local Medical War Committees on individual recruitment, representations against these recommendatons, and all other cognate matters.

Under the present arrangements practitioners are recruited to the Services through two channels: (*a*) practitioners whose names appear in the registers of Local Medical War Committees, and (*b*) practitioners dealt with centrally by the Central Medical War Committee, which consults Local Medical War Committees in appropriate cases. The second category comprises "young practitioners," the great majority of whom take junior hospital posts and who are recruited on the termination of those appointments. A special subcommittee has been appointed to advise on the recruitment of "young practitioners." The arrangements for the recruitment of volunteers for H.M. Forces continue.

Quotas

10. In order that practitioners registered under the National Service (Armed Forces) Act shall be drawn for recruitment to H.M. Forces fairly from the different areas, the Committee periodically, as the needs of the Services demand, allots quotas of practitioners to be provided by each Local Medical War Committee. In assessing a quota the Committee takes into consideration the type of area—i.e., whether it is a reception, evacuation, or neutral area—the number of practitioners who have already been recruited from the area, and the number, distribution, and classification of the medical profession practising in the area.

Hospital Appointments

11. In co-operation with Local Medical War Committees throughout the country and the Committee of Reference in London, the Committee has approved junior and senior wartime establishments for voluntary and municipal hospitals. Each hospital is allotted a prescribed number of A appointments (i.e., those house posts which can be occupied by newly qualified practitioners), of B2 appointments (i.e., posts which cannot be occupied by practitioners without previous experience), and of B1 appointments, which are senior posts (typically R.S.O., R.M.O., registrar, chief assistant at a voluntary hospital, and posts with a tenure of one year or longer carrying a salary of £350 per annum, with emoluments, or more, at a municipal hospital) The Young Practitioners Subcommittee is concerned with the recruitment of R practitioners holding A and B2 posts as they complete their appointments. The recruitment of holders of B1 appointments is dealt with in the first instance by the Local Medical War Committees in the Provinces and by the Committee of Reference in London, the recommendations of these Committees being passed to the Central Medical War Committee.

The Committee would like to take this opportunity of expressing its gratitude to hospital authorities for their valuable co-operation in preparing the establishments and in keeping the Committee informed of changes in the tenure of appointments.

Civilian Reserve List

12. The Committee has continued to maintain its list of practitioners who are available to assist in relieving the pressure of general practice wherever they may be required. The practitioners thus offering their services are, generally speaking, those whose practices have disappeared or been reduced by reason of evacuation or enemy action and retired practitioners who are willing to assist during the emergency. The civilian reserve list has been of great value in providing help for general practitioners in reception areas and for partnerships where one or more of the partners have joined H.M. Forces. The steady recruitment of practitioners to the medical branches of H.M. Forces and the growing need for doctors for civilian medical work have seriously depleted the Civilian Reserve List, and it is no longer possible for the Central Medical War Committee to undertake the provision of substitutes for practitioners joining the Services.

The Committee continues to maintain a list of practitioners who have intimated their availability for temporary public health work.

Emergency Medical Service

13. The Central Medical War Committee has appointed an Advisory Emergency Hospital Medical Service Committee to consider questions relating to the E.M.S. This Committee recommended to the Ministry of Health certain modifications in the terms of service of Class III officers, and its proposals were accepted in the main by the Ministry. The revised terms, which affect sessional fees, mileage, and the occupied-bed basis, were published in the *Supplement* to the *British Medical Journal* for November 2, 1940. The Committee also arranged with the Ministry of Health that the guaranteed period of employment of Class I and Class II officers should be extended to September 1, 1941.

General Matters

14. Apart from the detailed work of recruitment and the consideration of matters affecting the supply of, and demand for, medical personnel the Committee has dealt with numerous general questions. Among these are the question of compensation for civilian medical practitioners killed or injured in civilian defence duties, a question which the Committee still has under consideration in spite of the repeated refusal of the Ministry of Health to make any distinction between medical practitioners and other members of civil defence organizations; the appointment of honorary medical officers to battalions of the Home Guard; the rank of consultants to the Army

Conference of Local Medical War Committees

15. A large gathering of representatives of Local Medical War Committees was addressed by the Minister of Health, the Rt. Hon. Ernest Brown, M.P., on February 21, 1941. The Minister dealt with current problems in connexion with the recruitment of medical practitioners to H.M. Forces. At the close of his address questons were asked and answered.

Alien Practitioners

16. The question of the employment of friendly alien medical practitioners during the war has recently come into prominence. On the one hand, the recruitment of large numbers of British practitioners to H.M. Forces has resulted in a shortage in the medical services normally available to the civilian population. On the other hand, there are in this country at the present time a considerable number of alien practitioners well qualified in their own country who are anxious to make some contribution to the Allied war effort and at the same time to keep fresh their medical skill and their

contact with the progress of medicine. The Home Office has made arrangements for the temporary registration during the war of suitably qualified alien practitioners and for their employment in subordinate posts in hospitals. The Central Medical War Committee has undertaken the task of keeping a register of these approved practitioners and of providing their services to those hospitals requiring them.

Work of Local Medical War Committees

17. The Committee would like to take this opportunity of expressing its most sincere appreciation and thanks to the members of the Local Medical War Committees, and especially to the honorary secretaries, for the magnificent work they are doing on behalf of the profession. All their work is voluntary, and in many cases it is done at great personal sacrifice. The Committees form the link between the Central Committee and the individual members of the profession, and as such have been called upon to perform many arduous duties, often difficult and urgent in nature. Without their help the profession's war machinery could not function efficiently, and the Central Committee and every member of the profession are deeply indebted to them.

General

18. The Committee is aware that now that the available pool of practitioners has been seriously depleted its machinery cannot function with the fullest efficiency until there is established a priority or similar machinery to determine the priority of the various demands now being made on the medical profession. It has urged, and is urging, the taking of immediate steps to establish such a machinery.

BRITISH MEDICAL JOURNAL

19. Production and distribution of the *Journal*, though beset by many difficulties, have continued during the second year of war. The air raids upon London and the shortage of paper had to be contended with. Conditions of life and work during the heavy bombardments imposed a severe strain upon all engaged in producing the *Journal*. To meet the reduction in paper supplies, and the high cost of paper and postage, economy of space is effected wherever practicable, and the over-all size of the *Journal* has been kept down. The inflow of original articles shows little decline in volume and far exceeds the capacity to print them. The number of letters for publication continues very large indeed, and correspondence has occupied much space so that members may have full opportunity of recording experience and putting forward their views on the great variety of topics that keenly interest the profession in wartime. The principle followed in choosing material for publication is to give preference to that which has topical interest and value, and to afford medical men and women information and guidance which will increase their ability to serve the country. Thus the pages of the *Journal*, week by week, play an indispensable part in promoting the profession's war effort and in giving it a forum to discuss the problems of to-day and to-morrow. The *Supplement*, though much cut down in size, gives prominence to War Notices issued by the Central Medical War Committee and publishes miscellaneous information which must be brought to the attention of practitioners in wartime when other means of communication and discussion are limited or cut off. Advertisements have diminished in bulk, but that has been more than offset by the higher charges for advertising space.

Early last autumn, when things were at their worst in London, the *Journal* ended its 100th year of continuous publication, and the event was signalized by a Centennial Number dated October 5, 1940. This, though of modest size and scope, contained some historical matter and many gratifying messages of congratulation and good will from leaders of the profession at home and over-seas.

GENERAL PRACTICE

Increase in Medical Fees

20. A few Divisions have recommended their members to increase their private fees in view of the rising costs incurred in medical practice, and the Council considered whether the time had arrived for making a central recommendation on these lines. The Council has adopted the following recommendation: "That an increase of fees has been rendered inevitable by rising costs and that practitioners in general practice be recommended to increase their private fees, including contract fees, by not less than 20%."

Divisions are advised to take the necessary steps to give effect to this recommendation.

First-aid Posts

21. The Council has dealt with a number of questions relating to fees for medical practitioners attending first-aid posts in consequence of an air-raid warning. One question was the fee payable to a practitioner who attended at the first-aid post for a long period during the night—that is, extending over midnight. It has been agreed with the Ministry of Health that the definition of the term "any one day," for which a maximum fee of 3 guineas is payable, shall be from midnight to midnight, anything less than one hour's attendance on either side of midnight not being reckoned as entitling a practitioner to a fresh day's sessional fee.

Hitherto there has been no maximum fee that a practitioner may earn in sessional fees for duty at first-aid posts, although Class III officers in the E.M.S. are limited to an overriding maximum of 150 guineas in any six months. The Ministry proposes to apply this maximum to practitioners earning sessional fees at first-aid posts. The Committee has agreed to this proposal provided that the daily limit of 3 guineas is withdrawn.

Ministry of Pensions Medical Boards

22. The Council is making strong representations to the Ministry of Pensions against the inadequacy of the fees at present paid to medical practitioners acting as medical officers on the Ministry's medical boards.

PUBLIC HEALTH

Public Health Medical Officers and Wartime Cost of Living Bonus

23. A number of local authorities have had under consideration the payment of a cost of living bonus to their staffs. The Ministry of Health, on receiving applications from local authorities to apply the Whitley Council scale in the case of certain medical officers of health and other officers whose salaries are subject to Ministry approval, refused to sanction bonus payments to officers in this category earning more than £200 a year, the maximum to which the Civil Service bonus applies. The Association made representations to the Ministry that its action involves unfair discrimination between local authority officers of comparable status. The Ministry in reply stated that further consideration had been given to this matter in the light of the representations made and that the Minister had decided that he would not be justified in continuing to withhold his approval in the case of the particular officers concerned where the proposal is to pay them the bonus being paid already to other employees of the same authority. The Minister is accordingly prepared to sanction the payment of such bonuses to the public health officers referred to in areas where the local authority has granted a cost of living bonus to its staff. The Minister's decision, while it removes unfair anomalies in the relevant remuneration of local authority employees, does not reflect any approval in principle of the particular bonus scales which a particular authority may have adopted.

Vacancies during Wartime in the Whole-time Public Health Service

24. In April representatives of the Association and of the Society of Medical Officers of Health discussed with officers of the Ministry of Health the desirability of wartime appointments in the Public Health Service being filled on a temporary basis only for the duration of the war. It was urged that if permanent appointments to vacancies and new posts were made it would be prejudicial to those possible candidates who were serving with the Forces and might discourage others from offering themselves for commissioned service. While recognizing that local circumstances might determine policy in individual cases, the Ministry was urged to issue a circular to local authorities advising them in general to fill wartime public health appointments on a temporary basis. The Minister replied that while he shared the anxiety of the Association

and of the Society that nothing should be done which would unnecessarily prejudice the prospects of promotion or of future appointment of officers absent on national service, he felt that the decision whether to make a temporary or a permanent appointment in an individual case must be left to the responsible local authority to decide in the light of the circumstances. Wherever the matter comes before him for approval, however, he will certainly for his part place no obstacle in the way of a proposed temporary appointment in any appropriate cases. The Association's views have been approved in principle by the County Councils Association, the Urban District Councils Association, and the Rural District Councils Association.

Application of Askwith Memorandum to Temporary Whole-time Wartime Appointments

25. The Council has considered the application of the Askwith Memorandum salaries to (1) temporary whole-time public health and A.R.P. appointments, (2) hospital appointments within the Emergency Medical Service. The Council has authorized the acceptance for publication in the *British Medical Journal* of advertisements for temporary public health appointments offering the appropriate minimum commencing salary laid down in the Askwith Memorandum without increments. In connexion with advertisements for certain resident house officers at salaries less than the scale rate, the Council has not insisted upon the usual limitation of one year as the position is almost completely safeguarded by the recruitment procedure of the Central Medical War Committee.

The Ministry of Food National Milk Scheme

26. The Council has had under consideration the National Milk Scheme introduced by the Ministry of Food under which milk is available free or at reduced cost to expectant and nursing mothers and children under 5. It appears that in a number of areas the Medical Officer of Health or a member of his medical staff has been appointed local Milk Officer and that the Ministry has approved such appointments. The Council has informed the Ministry of Food that the Association takes the strongest exception to the practice of appointing Medical Officers of Health as Milk Officers for the purposes of the National Milk Scheme on the grounds that the scheme cannot be regarded as a health measure, but that it is primarily a scheme for the distribution of an essential foodstuff free or at a low price.

The Council has made representations to the Ministry of Health urging that the arrangements for the distribution of dried milk under the National Milk Scheme, which are not subject to medical supervision, should be administered separately from the arrangements for the issue of dried milk at local authority welfare and maternity centres, which are subject to medical supervision.

Salaries of Part-time Medical Officers of Health engaged in A.R.P. Work

27. As a result of the war many part-time medical officers of health have been called upon to undertake much increased work in connexion with A.R.P. and evacuation schemes. To carry out these additional duties it has been necessary for such officers to devote an increasing amount of time to their official work, and in many cases this has not been accompanied by a corresponding increase in remuneration. The Council supports the policy of increased remuneration for part-time medical officers of health whose duties have been materially increased as a result of A.R.P. and evacuation schemes without a corresponding increase in salary. In this connexion it is noteworthy that where it has been shown that a part-time medical officer of health is required to devote additional time to his duties on account of A.R.P. and evacuation work the Ministry of Health has approved for the purposes of grant applications by local authorities for an appropriate increase in his remuneration.

NATIONAL HEALTH INSURANCE

Insurance Capitation Fee

28. An application was made to the Ministry of Health earlier in the year for a wartime increase in the insurance capitation fee on the grounds of increased cost of living and practice expenses. The Ministry's reply is that legislation would be necessary to provide increased remuneration for insurance practitioners; that the cost of living part of Committee's claim involves a far-reaching principle of Gov ment policy from which it is impossible to depart until sim concessions are made generally, and that in regard to prac expenses the increase is considered to be too small to jus asking Parliament to amend the present financial structur the N.H.I. scheme. It has been decided to pursue the a cation on the ground of increased practice expenses.

Central Mileage Fund

29. The Ministry's reply to the Committee's application an increase in the insurance capitation fee covers also application for a wartime increase in the Central Mileage Fu The issue here is purely one of increased practice, an being pursued by the Insurance Acts Committee on this ba

Dispensing Capitation Fee

30. Negotiations with the Ministry of Health for a wart revision of the dispensing capitation fee resulted in the fe 2s. 6d. being increased to 3s. as from October 1, 1940.

Medical Benefit for Dependants of Men in the Forces

31. Repeated representations have failed to secure a mo cation of the Government's decision not to make provision medical benefit for the dependants of men in the Ar Forces. The view held by the Government is that the proved financial position of Service men and their dependa enables them to provide necessary medical attention for dependants without Government assistance.

Regional Medical Service: Re-examination of Members of Approved Societies

32. Following the suspension of the Regional Med Service medical practitioners who are asked by Appro Societies to undertake the re-examination of members h been advised that the fees to be accepted should be not than:

	£ s.
For an individual case	10
For a session of not more than two hours	2 2
For an examination at the insured person's house	1 1

* Plus mileage beyond two miles from the doctor's surgery.

National Formulary

33. The Ministry of Health has appointed a small commit on which the Insurance Acts Committee is represented, to sider the preparation of a wartime *National Formulary*, wh will take account of difficulties created by the war in obt ing certain drugs.

INDUSTRIAL HEALTH COMMITTEE

34. In view of the increasing importance of medicine the industrial field the Council has appointed a special C mittee (1) to further the co-ordination of industrial me practice with other branches of medical practice, in partic with general practice and the public health and hosp services; (2) to co-operate with Government Departments voluntary organizations in all measures affecting health industry.

The Committee has issued a statement for the guid of medical practitioners relating to salaries and condit of service for wartime industrial medical appointments. now proceeding with the preparation of its report.

SCOTLAND

Scottish Committee

35. Dr. Thomas Fraser, Aberdeen, and Dr. J. McCutcheon, Glasgow, were reappointed chairman deputy chairman respectively for session 1940-1. At a m ing of the committee held in December, 1940, it was ag that under existing conditions the committee would not at its accustomed intervals; but that meetings woul summoned as circumstances demanded.

The Chairman's, Highlands and Islands, and Hospitals committees have been reappointed so that any urgent ma can be duly considered and dealt with.

Maternity Services (Scotland) Act, 1937

36. Schemes under the above Act are now in operatio thirty-eight local authority areas. At a meeting of

Scottish Committee held in January, 1941, it was reported that the Corporation of Glasgow had submitted a scheme for a whole-time maternity service in the city. The Department of Health have informed the Scottish Secretary that the Glasgow Division will be afforded full opportunity of discussing the matter with the Department before any such scheme is officially approved.

Out-patient Departments : Royal Infirmary of Edinburgh

37. Following consultations between representatives of the Medical Committee of the Board of Managers of the Royal Infirmary of Edinburgh, representatives of the Edinburgh and South-East of Scotland Branch of the Association, and the Scottish Secretary, the Board of Managers have approved of the reorganization of the out-patient departments of the hospital on the lines approved by the British Medical Association.

Scottish Central Medical War Committee

38. Under war conditions a great part of the activities of the Scottish Office has been diverted to meeting the requirements of the fighting Services and the Emergency Medical Service for medical officers and other matters connected with the war effort. Under the voluntary scheme the Scottish Central Medical War Committee, on which the Scottish Committee of the Association is fully represented, was able to meet all the demands made. Local Medical War Committees in Scotland have been asked to supply, under the compulsory procedure, a quota of eighty practitioners for the months of March, April, and May, 1941. The Scottish Central Medical War Committee deals directly with all questions regarding the recruitment of R practitioners who have been qualified not more than two years and all holders of A, B2, and B1 posts. Steps have been taken to secure periodic returns regarding the holders of these posts, and to secure the fullest co-operation between the hospital authorities and the Scottish Central Medical War Committee in matters affecting the recruitment of members of hospital staffs.

Instruction in Treatment of Gas Casualties

39. Courses of instruction have recently been held in the various centres in Scotland dealing with recent developments in the treatment of gas casualties.

H. S. SOUTTAR,
Chairman.

AUDITORS' REPORT TO MEMBERS OF THE ASSOCIATION

Having examined the Balance Sheet, dated December 31, 1940, and Accounts with the Books and Vouchers of the Association, except as regards the Scottish Committee Accounts, which have been audited by Messrs. Kennedy Smellie and Co., and having received all the information and explanations we have required, we report that the Balance Sheet is, in our opinion, properly drawn up so as to exhibit a true and correct view of the state of the affairs of the Association according to the best of our information and the explanations given to us and as shown by the Books of the Association.

We have inspected the Lease of the New Building, the proposals for Building Leases on sites of 3, 4, 5, 6, and 7, Upper Woburn Place, and 13, 14, 15, 16, and 17, Tavistock Square, and 58, Burton Street, and the Disposition in favour of the Association of the premises 6 and 7, Drumsheugh Gardens, Edinburgh, and have verified the investments of the Association on General Account, on account of the Trust Funds and of the Office Staff Superannuation Fund.

We further report that we have examined the Accounts, with the Books and Vouchers, of the Medical Funds for whom the Association receives remittances, and found them correct.

JOHN W. BONE, *Treasurer.* H. S. SOUTTAR, *Chairman of Council.*

G. C. ANDERSON, *Secretary.*

FREE CHOICE OF DOCTOR

BY

S. F. MARWOOD, M.D., M.R.C.P.

Much has been written of late on the shape of things to come so far as medical practice is concerned. If a State Medical Service is contemplated, and, so far as I am concerned, it cannot come too soon provided the stultifying influence of traditional civil service methods is avoided, a multitude of problems have to be tackled before conception is translated into practice. That these problems can be solved I have no doubt, but in this brief article I am concerned with one that appears at first sight to be not the least of them—namely, free choice of doctor. In considering the views of different writers I am struck not so much by the frequency with which the need for such freedom is stressed as by the lack of any explanation as to how it may operate ; indeed, even its definition is avoided.

Need for Restricted Choice

We hear much these days of democratic principles embodying the rights of individuals to freedom of existence in various directions, but little stress is laid on the equally important principle that freedom is a relative term and may exist only in so far as it does not conflict with the welfare of the community as a whole. What is this free choice of doctor that is held to be almost sacrosanct? Strictly speaking, it presumes the right of the individual to call upon the services of any doctor at any time. Manifestly such a degree of freedom has never existed hitherto. In purely private practice a doctor is quite a free agent, while in all forms of contract practice, notably in national health insurance practice, there are imposed obvious limitations into which I need not go. It has to be admitted that free choice has always to some extent been restricted, and I suggest that its consideration is largely a bogy and should not, indeed must not, be permitted to hinder the full logical development of a State Medical Service, and that further restriction must be imposed for the greater good of the greater number.

The relation between doctor and patient is one of unusual intimacy, and I do not for one moment decry the factor of faith in the physician whom Osler, in his own inimitable style, described as the modern counterpart of the ancient shrine. I believe it is possible, however, in large measure to substitute faith in the profession as a whole for that in the individual doctor. A parallel exists in the affection for a particular hospital so often met with in that considerable class of patients who attend out-patient departments. If these people are able to develop faith in a large institution without special reference to individual members of its staff, it is merely a step further to a more comprehensive bestowal of confidence ; and should the objection be raised that hospital patients belong in the main to the less enlightened sections of the community, I would reply that, in my experience, the so-called better classes are just as susceptible to suggestion in medical matters as their less fortunate brethren. I do not belittle the value of a properly sympathetic attitude on the part of the doctor towards his patients' problems ; such an attitude should be encouraged and should obtain under all conditions of medical practice. Further, it would be idle to deny that some have better developed or more inherent in them than others, the faculty of creating confidence, but surely this difficulty is largely a matter of education, or rather the lack of it ; and I firmly

believe that, with proper education alike of doctor and public, the bogy may be laid.

Educating Doctor and Public for the Change

To deal in the first place with the doctor, I would suggest more careful instruction in our medical schools on the art of what, for want of a better term, may be called "handling" people. Students, whether unqualified or those recently qualified and engaged in house appointments, are, for the most part, young and impressionable and are readily influenced, and their approach to patients is likely to be determined by imitation of their teachers. It is no longer fashionable to speak of the bedside manner: the term has become almost one of derision as a result, doubtlessly, of the humbug with which it has so often been associated, but there is, nevertheless, more in doctoring than mere academic ability, as many a brilliant student has discovered to his cost. No one will suggest that a humane manner alone makes for a successful doctor in the best sense of the phrase, but what can possibly be said in favour of its absence? Patients, in the main, are no longer to be gulled by practitioners whose only stock-in-trade is a bedside manner, and the fact is that the good doctor is one who combines reasonably both manner and ability.

It happens at times that a general practitioner, seeking a bed for a case he believes to be urgent, telephones a hospital and is greeted by a member of the junior staff in accents that are far from courteous: the catechism that follows is often curt and the comments supercilious. Such an attitude is by no means invariable but is much too common, and it is, I fancy, encountered more often at the large teaching hospitals. It probably does no more than cause passing irritation to the practitioner, but it certainly does not suggest a good preparation for the wider life that lies before the young doctor outside hospital. If he can behave thus to a professional senior it is evident that a considerable change has to be effected in his manner before he becomes acceptable to patients, and such a change often takes time even when the need for making a living introduces the factor of urgency. In a salaried service such a factor is inconsiderable, and herein lies one danger if the public are to be deprived of most of their freedom of choice. It *is unnecessary to enter into details*, but that members of the senior staffs of our hospitals and particularly of our large teaching hospitals can, by example and instruction, do much to minimize this danger is obvious.

As for the general public, it should not be difficult to demonstrate to them that insistence on the preservation of the principle of free choice must militate against the effective working of a State Medical Service with its manifold advantages of *early diagnosis and prompt* treatment divorced from financial anxiety. It should be put to them that, while it is right and proper that the resources of the medical profession are available at all times in case of need, it is selfish to demand similar service from the individual doctor. Under present condition the vast majority of doctors are, except for all-too-brief interludes, liable for service during every minute of their existence. Can such an existence be justified by any reasonably minded person? Further, can the continuation of such a system, necessitated by the preservation of present ideas of freedom of choice, seriously be contemplated in a State Medical Service? No thoughtful person will doubt the answer to these questions.

It would seem to me that, with the advent of a State service, freedom of choice must be limited to consultations at appropriate centres at appropriate hours, and that, unless the present uneconomic system is perpetuated whereby several doctors are visiting the same small district or even the same street on any one day, it must be dispensed with in patients' homes except possibly in those cases where a second opinion is needed. There will be difficulties and objections of various kinds in the early days, but is this not the fate of every progressive innovation affecting human welfare? For an example we need cast our minds back no further than the early days of the National Health Insurance Act, yet I warrant there be few who will dispute the tremendous social value of the Act.

An "Infinitely Superior" Service

Dr. S. T. Pybus, in a recent article, outlines a scheme for a State Medical Service. As he admits, it is revolutionary, and I think rightly so. In the main his suggestions appear to me to be sound, and I like among other things his provision for postgraduate facilities, whereby practitioners would be able to maintain and enlarge their medical education, and thus be better fitted to place early at the disposal of their patients those varied methods of investigation which even to-day are so often used too late. I would go further and make such refresher courses compulsory, with an appropriate test at their conclusion and some sort of penalty for slackers. It would not be possible then to hear the occasional comment, "I have never read a medical book since the day I qualified" and, what is more important, further incentive would be given the public to accept a State service.

We must cease worrying about freedom of choice and give something of far greater value in the form of a service infinitely superior to that which has existed hitherto. We general practitioners have often been up in arms against the inevitable inroads of the public health services into what we have regarded as our preserves, although I suspect it was more often the manner of the encroachment than the encroachment itself which evoked our resentment; yet who will deny that these services, not so much by virtue of the superior ability of the medical staff as by organization and team work, have effected a greatly improved standard of health in the community. So will it be with a State service.

To summarize, I believe that even to-day the great majority of patients, however ardently they may in the first place desire a particular doctor, will not fail to be completely satisfied by any doctor who deals faithfully and conscientiously by them. Sick patients, however, under any system will always resent the doctor who deals brusquely with them, no matter how efficient he may otherwise be. Given proper education of doctor and public, I believe that as the years of a State Medical Service pass by, and patients come increasingly to rely on a sympathetic handling of their illnesses by doctors whose efficiency is guaranteed by the State, less and still less will be heard of the question of free choice of doctor.

MEDICAL REPORTS ON A.T.C. ENTRANTS

The Air Ministry has issued for use by Honorary Medical Officers of Squadrons of the Air Training Corps for the examination of entrants, an official form of medical report, together with explanatory notes. The candidate is asked to answer six questions regarding his medical history, and the Medical Officer is asked to report on the physical condition on the following form:

PHYSICAL EXAMINATION

A. HEART. Size.
Sounds.
Rhythm.

B. LUNGS.

C. ABDOMEN

D. VISION: R. 6' Colour Vision.
L. 6' Normal or otherwise.

For Air Crew vision not to be worse than 6/18 in either eye without glasses. For Ground duties vision not to be worse than 6/60 correctible to not worse than 6/12 in either eye.

GROUND DUTIES.—While for certain trades a high standard of visual acuity is required the lowest visual standard at present accepted for men entering the Royal Air Force is as follows: If a candidate has lost the vision of one eye, completely or partially, he can still be accepted in exceptional circumstances, if the vision of the other eye, with or without glasses, is not less than 6/12.

E. EARS. Hearing. For Air Crew duties candidate must be able to hear a forced whisper at 20 feet distance with either ear tested separately. For Ground duties candidate must be able to hear a normal speaking voice from 10 feet away.

F. GENERAL EXAMINATION: Any Physical abnormalities.

REMARKS of Hon. Medical Officer.

Date ..... Hon. Medical Officer of No. ... Squadron A.T.C.

NOTE.—(1) Considerable help can be given to the Hon. Medical Officer by filling in names, date of birth, etc., by Squadron Officer.
(2) All Medical forms to be returned to Officer Commanding in plain envelope to Squadron concerned and not in Squadron name.

CONFIDENTIAL. A.T.C. Form M.1.

GENERAL MEDICAL EXAMINATION OF A.T.C. CADET

(Not for entry into R.A.F.)

Surname .....
(in BLOCK letters)
Christian Names ..... Date of Birth .....
Have you any history of:—
1. Sleepwalking or Bedwetting .....
Fits or convulsions of any kind .....
2. Pneumonia or Pleurisy .....
Asthma and Hay-fever .....
3. Rheumatic Fever, Diphtheria or Scarlet Fever .....
Weak or Strained Heart .....
4. Eye trouble or Inflammation of Eyelids .....
5. Earache, Discharge from the Ear, Ear, Nose or Throat trouble .....
6. Operations .....

The explanatory notes are as follows:

AIR TRAINING CORPS

NOTES FOR HONORARY MEDICAL OFFICERS

(To be read in conjunction with A.T.C. Form M.1.)

The following is an outline of the standards of physical fitness required:—

1 (a) The boy must be free from any disease or physical defect calculated to render him unfit for his duties in the Royal Air Force.

(b) He must be fit or likely to be fit when old enough for entry to serve at home and abroad under active service conditions.

(c) He must not suffer from any of the following defects: (i) Fits, chronic bronchitis, or winter cough; (ii) a weak constitution, such as evidence of tuberculous disease; (iii) contraction or deformity of chest, joints, or spine; (iv) disease of the heart or lungs; (v) severe varicose veins or haemorrhoids; (vi) discharge from or disease of either ear; (vii) enlarged lymphatic glands; (viii) kidney disease; (ix) hyperthyroidism.

(d) A personal history of acute rheumatic fever, more than one attack of unconsciousness, bed-wetting, or asthma will require careful consideration at the time of the medical examination.

2. **Standards of Vision.**

(a) *Air Crews:* (i) Visual acuity below 6/18 in either eye debars consideration for air crew duties; (ii) defective colour vision debars consideration for air crew duties.

(b) *Ground Duties:* While for certain trades a high standard of visual acuity is required, the lowest visual standard at present accepted for men entering the Royal Air Force is as follows:—(i) If a candidate has lost the vision of one eye, completely or partially, he can still be accepted in exceptional circumstances, if the vision of the other eye, with or without glasses, is not less than 6/12. Myopia or more than minus 7 in any meridian is, however, a bar to acceptance. (ii) Defective colour vision is not a bar to entry, except in certain trades.

3. **Standards of Hearing.**

(a) For air crew duties normal hearing is required—that is, forced whisper must be heard at 20 feet with either ear, the other being blocked. (b) For ground duties the standard is not so high, but the man must be capable of easily hearing a spoken voice at a distance of 10 feet. For certain trades, however, normal hearing is required.

4. The record of the medical examination is made on A.T.C. Form M.1, and in the "remarks" space the examining medical officer should state whether or not he considers that the boy is likely to be fit for (a) air crew duties and/or (b) ground duties.

Correspondence

Certificates for Additional Milk

SIR,—I have just received a supply of forms, issued by the Ministry of Food, to be used for "additional supplies of milk to persons suffering from certain diseases," and if anything more futile was ever devised even by a Government Department it has not been my fortune to see it. The arbitrary list of "the only diseases in respect of which supplies of milk may be recommended" has evidently been compiled from a dictionary of medical terms, without reference to a doctor or even to a housewife. Here it is, with comments.

1. *Active tuberculosis of all types and of all organized tissues.* I am at a loss to understand what subtle type of tuberculosis eludes the comprehensive "all types" and requires the elaboration "of all organized tissues." This also seems to beg the question: "Which tissues of the body are not organized?"

2. *Silicosis.* Why pick on silicosis? Admitting that it predisposes to tuberculosis, does not bronchitis with emphysema demand precisely similar treatment?

3. *Conditions in which the patient is unable to swallow solid food by reason of an affection of the mouth, throat, or gullet.* . . This specification appears to exclude thoracic aneurysm, mediastinal growth, or thyroid cancer. And the rules for the disposal of the form mean that the householder (probably the patient) and the dairyman must be told of a cancer of the oesophagus, while we labour to keep the patient cheerful.

4. *Gastric, duodenal, or anastomotic ulcers.* The bureaucrat could not resist the appeal of the sonorous when "peptic ulcer" would suffice. And what about all the cases of gastritis, many of them in valuable workers, which may produce ulcers or in which the patients may be otherwise incapacitated unless they can be kept on a diet rich in milk?

5. *Illnesses characterized by high and prolonged f* "high" not enough, and what is the duration o longed"?

6. *Post-operative conditions after major operatio* would appear to allow milk for an amputation neuro not for cardiac failure following dental extraction.

It is reasonable to assert that 90% of invalid diet more than a bare minimum of milk. It is not, perhaps in Whitehall that almost all cereals require milk eithe cooking or in the eating, and to suggest that less ailments can do without is absurd. A working cou often make do with half a pint a day for their tea; she nurse him through gastric "flu" out of that?

If the certificate of a medical man that extra milk is cannot be accepted as adequate proof of the *bona fide* case, then the list of diseases must be extended. giving prolonged thought to the matter, I should say want extra milk available for arthritis, cardiac failure, of all kinds, goitre, gout, hypertension, jaundice, nephri doubt you can add another half-dozen yourself.—I am,

Grimsby, May 3. E. J. THOR

State Medical Service

SIR,—Dr. Alan Marsh in his interesting letter (*Supp* April 19, p. 47) states: "A fixed salary destroys in and ambition." He does not suggest why; he just st dogmatically and definitely, *deus-ex-machina*-like: a salary destroys initiative and ambition. May I, how fixed salary man, ask him if his declaration, his edict, to all those enjoying security of income? These, as schoolboy knows, include the Archbishop of Canterbu all his bishops; the Prime Minister and each and every m of his Cabinet; every admiral in the Navy, every gen the Army, and every marshal in the R.A.F., and al officers and men; it includes 99% of the officers of all business concerns and of the railways, the B.B.C., e includes the headmasters and staff of the public, privat State-aided schools; the Civil Service; the judges; many trates who dispense justice; and all the staffs of municip It does not include such varied ranks of society as profe men in private practice, small shopkeepers, hawkers, milli motor magnates, and, I believe, a number of the clergy.

Medical officers of health have from time immemorial accused of encroaching on the preserves of the general titioners, and stealing their thunder here, their lightning This constant erosion is presumably in Dr. Marsh's view their desire constantly to secure renewed stocks of init and ambition in order to have more to destroy.—I am, et

HUGH PAUL, M.D., D.P.H.,
May 7. Medical Officer of Health, Smethwi

Postgraduate News

ADSORBENT OF ALIMENTARY TOXINS

CARBACT

BRAND

ACTIVATED CHARCOAL TABLETS

FORMULA:

Activated Charcoal	3 grains
Bismuth Tribromphenate	1⅛ grains
Ext. Rhei Sicc.	⅜ grain
Excipient q.s. to	7½ grains

INDICATIONS:

All conditions due to alimentary intoxication, whether bacterial or chemical
Severe gastro-intestinal disturbances
Flatulent dyspepsia
Intestinal distension
Poisoning arising from food, vegetable and inorganic poisons
Gastro-enteritis
Diarrhœa and dysentery

AVAILABLE IN PACKETS OF 100 TABLETS

RAPID BLOOD REGENERATION

FERRAEMIA

BRAND TABLETS

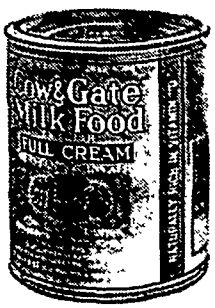
FOR ANÆMIA

FORMULA:

Ferrous Sulph. Exsicc.	2¾ grains
Dried Yeast	2 grains
Copper Sulphate	1/100 grain
Manganese Hypophos.	1/32 grain
Excipient	⅝ grain
Chocolate coating q.s. to	8½ grains

INDICATIONS:

Hæmorrhagic Anæmia, Acute and Chronic
Anæmia of Pregnancy
Nutritional Anæmia
Idiopathic Hypochromic Anæmia
As a tonic during convalescence and debilitated conditions



AVAILABLE IN BOTTLES OF 60 TABLETS

Manufactured in England by

74-77, White Lion Street, London, N.1 and at 19, Temple Bar, Dublin

MODERN VIEWS OF INFANT FEEDING

"The best available substitute for human milk is a good variety of dried milk. Such milk is safe, in that it is free from tubercle bacilli and pathogenic organisms; its vitamin and iron content is adequate; it is quickly and easily prepared and thereby error is reduced to a minimum; and it has been made to resemble human milk to an extent that could never be achieved in the average home." —"Lancet" 3.7.37

Cow & Gate Milk Food

This view is now well established in Medical Practice, as is also the view that Cow & Gate Milk Food not only ensures bacteriological purity, provides adequate vitamins and minerals, is easily digestible and is simple to prepare, but also has been amply shown to provide the Medical Practitioner with the most responsive Milk Food for his difficult cases.

ANALYSIS

COW & GATE MEDICAL AND RESEARCH DEPT. B.M.J., GUILDFORD, SURREY.

the fluid was only faintly opalescent and was under normal pressure, stupor, confusion, and irritability persisted. At 11 a.m. on the 17th she began taking sulphapyridine by mouth—15 grains (two tablets) six-hourly. As it was suspected that the drug might be responsible for the failure of her mental symptoms to show improvement, corresponding with the almost normal appearance of the cerebrospinal fluid, the dosage was reduced at 11 p.m. to 7½ grains six-hourly, and the drug was omitted altogether twenty-four hours later.

On the morning of the 18th she was beginning to improve and was able to answer simple questions. On the 19th she was more alert and felt much better; neck rigidity was less marked. By the 20th all signs of meningeal irritation had disappeared; she was mentally normal, and spasm of the hamstrings, neck rigidity, and headache were entirely absent. The temperature, however, rose slightly above normal, and one tablet of sulphapyridine was given six-hourly during the next twenty-four hours. On the 21st neck rigidity and a positive Kernig's sign were again noticed, and as she began vomiting the dose was reduced to one tablet eight-hourly, the drug being discontinued on the 22nd. Next day there were no abnormal symptoms or physical signs, and she made a rapid and uninterrupted recovery.

Case IV

This patient, a girl aged 10, was taken ill with headache and vomiting on April 14, 1940. She became delirious on the 16th and was admitted to hospital in the afternoon in an unconscious and extremely restless condition. Rigidity of the neck and a well-marked positive Kernig's sign were found, but no petechiae could be seen. The cerebrospinal fluid was under greatly increased pressure, was turbid to the naked eye, and contained a large number of pus cells and meningococci.

Sodium sulphapyridine 3 c.cm. was given intravenously on admission and intramuscular injections of 3 c.cm. were continued four-hourly during the next sixteen hours. The following morning a lumbar puncture showed the cerebrospinal fluid to be almost clear and under normal pressure. She was much better, and was willing to take tablets by mouth. Two tablets (15 grains) four-hourly were substituted for the injections. On the 18th she again became delirious, with pronounced neck rigidity. As the spinal fluid was quite clear and was under normal pressure the administration of sulphapyridine was discontinued. On the 19th there was a noticeable improvement in her general condition, and by the 20th she had lost all her symptoms and physical signs. Her convalescence was uneventful.

Case V

A girl aged 11 was admitted to hospital on January 24, 1941, twenty-four hours after the onset of the first symptoms—headache and vomiting. She was complaining of intense headache, but answered questions promptly and intelligently, and there was no restlessness. She had a good deal of head retraction, and the lower limbs were held flexed at the hips and knees. No petechial haemorrhages were to be seen. Lumbar puncture showed purulent fluid under increased pressure; from this meningococci were grown.

The girl tolerated sulphapyridine well by mouth, and was given 22½ grains on admission and 15 grains four-hourly for the next forty-eight hours. On the 25th head retraction and spasm of the erector muscles of the spine became more intense; but there was no headache and she remained quiet and rational. During the evening of the 25th she became restless. But next morning she was confused and quite unmanageable; neck rigidity was still well marked. The cerebrospinal fluid was under normal pressure, and was only faintly opalescent. The dose of sulphapyridine was reduced to 7½ grains four-hourly, but, the restlessness not improving, the drug was omitted at 5.30 p.m.

On the morning of the 27th the patient was quite rational, and rigidity of the neck and spasm of the erector spinae were much less noticeable. She continued to improve rapidly, and had lost all her abnormal signs by the morning of the 29th. She made an uninterrupted recovery.

Discussion

The most striking feature of the five cases reported above is the persistence of their cerebral symptoms in spite of intensive sulphapyridine treatment. Although this type of clinical history was not at all unusual before sulphapyridine therapy of meningococcal meningitis was introduced, the average patient responds to the drug so rapidly and so well that some explanation must be found to account for those cases which are exceptions to this rule.

The first and most obvious answer would be to call these cases drug-resistant and to suggest that their symptoms were due to persistence of the infection. A closer study of the case histories shows that this view is untenable. The appearance of the cerebrospinal fluid, which in this disease is a very reliable guide in assessing the response to treatment, showed gradual return to normal in every case. The patients' symptoms, however, either became progressively more severe (Cases I and II) or returned after a transient improvement (Case IV). The contrast is even more marked in Case V, whose first symptoms of cerebral irritation appeared on the third day of treatment, although the cerebrospinal fluid was by then under normal pressure and was almost clear. The strongest point against the infective origin of the cerebral symptoms is the marked improvement which occurs so rapidly after withdrawal of the drug.

These facts not only contradict the theory of a drug-resistant infection but seem to indicate that the persistence and increasing severity of the mental symptoms were due to the toxic effect of sulphapyridine. If this view is accepted it is easy to see why improvement follows so quickly when the drug is omitted; also, the reason for the discrepancy between the clinical picture and the appearance of the spinal fluid becomes obvious. It now remains to be seen how this type of toxic reaction can be recognized.

It is often extremely difficult to decide whether cerebral symptoms persisting after the second or third day of treatment are due to the disease or to the drug. All the mental symptoms which our cases have shown—irritability, restlessness, confusion, and stupor—are part of the clinical picture in acute meningitis, and by themselves may easily be ascribed to the infection. The differential diagnosis is least difficult in patients who are mentally normal when first seen, and whose cerebral symptoms appear on the second or third day of treatment (Case V). The origin of the symptoms in such cases is obvious. Others show a clearly marked period of remission, after which the mental symptoms return in spite of continued intensive treatment. In some patients, again, the transition between the two sets of symptoms is imperceptible, and the diagnosis cannot be made on purely clinical grounds.

The temperature chart affords no assistance, being a most unreliable guide even in uncomplicated meningitis. The degree and type of pyrexia vary from case to case. Some of our patients have been apyrexial throughout their stay in hospital. Similarly, cerebral symptoms may occur in association with a raised as well as a normal temperature. Clinical signs, such as head retraction and spasm of the hamstrings, are also misleading. These sometimes persist for days into convalescence, and their presence in association with cerebral symptoms must not be taken as a certain indication that the infection is still active.

If it is suspected that the persistence of the symptoms is due to the toxic effect of the drug a lumbar puncture should be made without delay. If the fluid is clear and under normal pressure, administration of the drug must be discontinued immediately. Where this is done in time the prognosis is favourable and no additional therapeutic measures are required. On the other hand, if administration of sulphapyridine is continued in these circumstances the outcome of the condition is likely to be fatal. The assistance afforded by lumbar puncture in the diagnosis of these toxic reactions raises the question whether this procedure should be carried out daily in all cases. We believe that this is unnecessary as a therapeutic measure

in patients who respond well to drug treatment and in the absence of symptoms of increased intracranial tension. On the other hand, a sample of the cerebrospinal fluid should be obtained from every patient whose cerebral symptoms fail to clear up within two or three days after the beginning of treatment and in all cases in which these symptoms set in during the course of treatment or recur after a transient improvement.

It is unlikely that any constant relation exists between the concentration of sulphapyridine in the blood or cerebrospinal fluid and the appearance of this type of toxic reaction. Although the amount of sulphapyridine given in the first four cases is much higher than the dose which would be used to-day, a number of patients have taken similar large doses without ill effect. On the other hand, the dosage in Case V would not seem to be excessively high, and yet the patient developed toxic manifestations. It is probable that individual sensitivity to the drug plays an important part in the causation of these toxic symptoms.

Conclusion

The number of cases treated at this hospital during the past fifteen months is too small to allow us to draw any definite conclusions as to the incidence of cerebral symptoms attributable to sulphapyridine treatment. It seems, however, that they are not at all uncommon. It is safe to say that the incidence of this type of toxic reaction is greater among children than among adults, and those receiving the drug by the parenteral route are more liable to it than are those taking it by mouth.

Summary

Five cases of meningococcal meningitis showing persistent cerebral symptoms are reported.

It is suggested that these symptoms were due to the toxic effect of sulphapyridine.

We have to thank Dr. T. Peirson, medical officer of health to the city of Plymouth, for permission to publish the case notes.

LOSS OF VISION FOLLOWING HAEMORRHAGE

BY

H. L. TIDY, M.D., F.R.C.P.

Physician to St. Thomas's Hospital; Colonel, Consulting Physician to the Army at Home

Loss of vision following haemorrhage attracted considerable attention in the earlier decades of the nineteenth century, when blood-letting provided a cause which fortunately no longer operates. It is a rare complication, and surprisingly so after haemorrhage due to accident or trauma, such as occurs in warfare.

The mode of development of the disturbance of vision falls into two groups. In the first group the disturbance closely or immediately follows the haemorrhage. Thus on recovering from syncope due to loss of blood the individual finds that the vision is entirely lost or is impaired in varying degrees. With the more severe grades, especially complete blindness, there is often considerable emotional disturbance, and for this reason the condition has been held to be functional. But more probably it is due to sudden anaemia of the cortical visual centres or of the retina, analogous, as Rolleston points out, to the impairment of hearing which may occur. There are no changes in the fundus. The disturbance is transient, recovery beginning immediately and being as a rule complete and permanent. This group is not further referred to.

The second group is more important, but is undoubtedly rare. In this type there is usually an interval after the haemorrhage before vision is affected. The impairment may then advance for several days before recovery begins, and some degree is often permanent. Oedema of the disk is nearly always recognizable, though the swelling may be only slight, and oedema of the retina has been described in recent cases. Optic atrophy develops in permanent cases.

The Literature

Harbridge (1924) could find only 18 cases recorded in the literature between 1912 and 1924, a period which included the last war. There has been much discussion as to what is the cause or lesion; it is generally agreed that a combination of several factors is necessary, and possibly these are not identical in all cases. It is probable that blindness never follows haemorrhage in an individual who is in normal health. Haemorrhage alone is not a sufficient factor, since permanent or prolonged disturbance of vision does not follow a single haemorrhage, however profuse, and there is no recorded instance of permanent loss of vision in the bleeding of haemophilia.

Anaemia likewise is not a sufficient cause by itself. In the Victorian and pre-war era two great anaemic diseases were prevalent—pernicious anaemia and chlorosis. For the purposes of a discussion on the ophthalmological complications of diseases of the blood, Panton (1935) investigated a series of 117 consecutive cases of pernicious anaemia admitted to the London Hospital between 1911 and 1920. In this series there were only two cases in which there was disturbance of vision. In one case the patient complained of dimness of vision, and the ophthalmic surgeon's note reads, "Oedema of both disks and retinae: about 2D of swelling in right disk, less in left disk. Many linear haemorrhages in fundi." In the other case the patient complained of rapid loss of vision, ending in almost complete blindness associated with complete optic atrophy. She had, in addition, fairly advanced cord changes. This is the only case recorded in the literature of severe loss of vision occurring in pernicious anaemia. In chlorosis it may be accepted that papilloedema is occasionally found, and there are many discussions in the older literature as to its significance. Nevertheless it is clearly not of a high degree, and is usually recorded as blurring or haziness of the edge of the disk. It is noteworthy that Clifford Allbutt (Allbutt and Rolleston, 1909), who must have had an enormous experience, stated that he had never seen a case of permanent blindness developing in chlorosis. Before the days of modern treatment the oozing from haemorrhoids sometimes reduced the subject to a state of extreme anaemia, and a profuse haemorrhage might then occur. Nevertheless there is no instance in the literature of disturbance of vision in this condition.

There is little evidence on which to assess the influence of oedema. Certainly gross oedema, apart from a nephritic origin, has no part in producing permanent loss of vision, but most of the recent ophthalmological examinations, when made shortly after the onset, record oedema of the retina and some swelling of the disk, though the latter may be slight. Such localized oedema might well occur after a severe haemorrhage or after a more moderate haemorrhage in an otherwise debilitated subject. It is not impossible that shock may be an important factor.

Site and Circumstances of Haemorrhage

The site of the haemorrhage is of interest. Fries (quoted by Barr, 1934) gives the statistics of 106 cases recorded up to 1876 as follows: Gastric ulcer, 36%; uterus, 25%; epistaxis, 7%; blood-letting, 25%; accidental wounds, 5%. In those days the condition especially attracted attention as a sequel of blood-letting, and Gowers refers to this at some length in his *Medical Ophthalmology*. He states that loss of vision occurred only after repeated bleedings

and never after a single blood-letting, however large; and he points out that the subjects were all in bad health previously. He expresses the opinion that a single haemorrhage, however profuse, never results in permanent loss of vision in an otherwise healthy subject. This is borne out by the extraordinary rarity of this sequel in accidental haemorrhage. There appear to be only three cases recorded in the last war—two by Pincus (1918) and one by Terrien (1921)—and there is a striking similarity in the histories. In all three cases a lower extremity was crushed, gas gangrene supervened, and amputation was performed several days after the wound. It is now known that serious metabolic disturbances develop in such circumstances. No doubt there are other unpublished cases.

Harbridge gives the site of bleeding in the 18 cases published between 1912 and 1924 as follows: peptic ulcer, 6; uterus, 6; nose, 3; and 3 of accidental haemorrhage, these last being the cases of Pincus and Terrien. The comparative frequency of epistaxis is interesting. Harbridge records a personal case in which epistaxis had been recurrent and severe since childhood, and the history suggests a blood-deficiency disease, such as thrombocytopenia and hypoprothrombinaemia.

The circumstances of the haemorrhage vary considerably. Most commonly there is a history of repeated haemorrhage, the bleeding which preceded the disturbance of vision usually but not always being severe. In other cases there has been prolonged haemorrhage—for example, after childbirth. Rarely there has been only a single haemorrhage, but the subject has been in a debilitated or toxic state. In Harbridge's case associated with epistaxis, impairment of vision has occurred on three occasions separated by several years. No age is immune: most of the subjects have been between 40 and 50, but cases are recorded in childhood and in old age. There is little difference in its incidence in the two sexes. A striking feature is the interval which commonly elapses between the haemorrhage and the recognition by the patient that the vision is impaired. The initial complaint is usually made between the third and eighth days. The longest recorded intervals are eighteen and twenty days. The impairment, however, may be recognized shortly after the haemorrhage, as on recovery from syncope; and it is said that this was comparatively common in blood-letting cases but, as Gowers states, not after a single bleeding. It is possible that in these instances the initial blindness belongs to the first group, and the more permanent type follows. The diminution of vision when first noticed may vary from blurring to complete blindness. In the partial grades it tends to increase for three or four days, and then improvement may set in. Recovery may be rapid at first and then continue slowly for weeks or months. Several observers agree that the upper part of the field of vision is less affected and recovers more completely than the lower part. If the loss of vision becomes complete it usually remains so permanently, but Lister (1929) mentions a case in which recovery was perfect three months later. The disturbance of vision is generally bilateral: but it may be unilateral, or the degree of impairment may be different in the two eyes.

As to the final result, in 33% of the cases blindness is complete and permanent in both eyes, and in 50% there is no improvement from the maximum loss. About 10% recover good or complete vision. In the remainder there are varying degrees of improvement in one or both eyes.

Findings in the Visual Field

Visual field findings show great variations. In Bamford and Barber's (1940) case there was progressive concentric contraction of the fields. In Barr's case there were central scotomata with enlargement of the blind spots and only slight contraction of the colour fields. There may be sector-like defects or paracentral scotomata. Ophthalmological changes are also inconstant. When examined shortly after the onset most observers record swelling of the optic disk, which may be intense or as little as one dioptre, or only blurring of the margins. In Lister's case, referred to above, with complete blindness there were no *fundus changes*. In several cases oedema of the retina has been recorded. Goerlitz (1920) was able to make a pathological examination of the eyes from a man who died ten days after the onset of blindness following haematemesis. The principal changes were intense oedema of the disks and oedema of the retinae. Goerlitz states that the changes resemble those found in intoxication amblyopia such as is caused by methyl alcohol.

In cases of definite permanent impairment of vision, when seen several months after the onset, all observers agree as to the presence of optic atrophy, often of a high grade, with no other appreciable changes in the fundus. The optic atrophy may be either primary or secondary.

Local Oedema an Important Factor

There is no agreement as to the essential pathological lesion, but it is generally accepted that local oedema is an important factor. Degeneration and death of the ganglion cells of the retina and their nerve fibres, resulting in optic atrophy, has been suggested. In such an event if the disk had been swollen the atrophy would be secondary in type, otherwise it would be primary. Retrobulbar neuritis has also been suggested; and this could account for cases in which no change was found in the fundus in the early stages, and the final optic atrophy could be primary or secondary in type. This would agree with the observation of Goerlitz that the pathological changes resembled those produced by methyl alcohol and quinine. Unfortunately there are no pathological observations of *the nerve trunk or tracts*.

I saw the following case in consultation with Dr. J. L. Lock.

Case Record

The patient, a primipara aged 30, was confined on the evening of June 20, 1936. It was known that she had been anaemic since childhood, and two blood counts taken at an interval several years previously both showed approximately 3,500,000 red cells per c.mm. and haemoglobin 50%. She had been given occasional bottles of an iron mixture. Menstruation had been within normal limits. In spite of the anaemia she had been reasonably active.

Pregnancy was normal throughout, except that oedema of the feet and ankles of a somewhat marked degree had been observed for the last few weeks, but several examinations had not revealed any albuminuria. Confinement was uneventful, except that the loss of blood was noted to be more than normal but not sufficient to cause anxiety, and it ceased without special measures. On the following morning, June 21, she was mentally confused, unaware of her surroundings, did not realize that she had had a baby, and looked very anaemic. I saw her on the same day. The temperature was normal and the pulse about 100. There was considerable oedema of the feet. The blood pressure was 140/80. The fundi were normal. The urine contained a trace of albumin but no casts. The blood urea proved to be 32 mg. per 100 c.cm. The blood count showed 2,800,000 red cells per c.mm. and haemoglobin 36%. The white cells were approximately normal. I considered that she was suffering from anaemia of pregnancy developing on a chronic constitutional anaemia. She was given a blood transfusion and was put on liver extract and large doses of iron. Ten days later the mental condition had almost cleared and the anaemia was improving. She then complained that her vision was misty and that she could not see clearly, but little attention was given to her complaint. Three days later, for the first time, she was given a letter, and it was then discovered that she was unable to read it. On examination she was found to have bilateral central scotomata, and there was 2D of swelling of the disks

but no other fundus changes. The urine was normal and the blood count gave 3,800,000 red cells and 50% haemoglobin. Four months later the vision had recovered completely and the fundi were normal. The blood had improved to 4,500,000 red cells and 80% of haemoglobin.

It would be interesting to know if any cases have been observed in the present war.

AN UPPER-ARM SPLINT WITH A SHOULDER YOKE AS MAIN SUPPORT

BY

J. KVITTINGEN, M.D.(Norway)

There are already a great number of different types ot splints available for the treatment of injuries of the upper arm, and the introduction of yet another device is certain to arouse criticism. The method which is here described was first employed under practical conditions when existing appliances had been found to be unsatisfactory. The main defect of all the types hitherto in use seems to be that their fundamental point of support is on the hip-bone, and in order to keep this support in position it is necessary to use a large number of tight straps; in spite of these there is a marked tendency for the splint to slip downwards and forwards.

Application of the Method

While working as a military surgeon in the Abyssinian army on the southern front I found that the existing methods of splintage were in many ways unsatisfactory. Cotton-wool padding became rapidly infested with lice and bugs, and patients complained bitterly of the discomfort and irritation. In order to overcome these difficulties I tried fixing the splint by means of a main support consisting of a shoulder yoke. This method was first tried out on a soldier with a compound fracture of the humerus. The first splint was moulded on an unwounded man of approximately the same build, and was made in plaster-of-Paris on the framework of a ladder-wire splint. In the first place a plaster-of-Paris yoke was laid across the shoulders in the manner of a sailor's collar. The ladder-wire splint was incorporated from behind the middle of the yoke, and was bent over the shoulder and downwards to a point two fingerbreadths below the clavicle. From this point the splint was bent to form a right-angle and allowed to follow edgewise the anterior aspect of the upper arm, which was thus retained in the correct position. A vertical support was attached to the underside of the splint immediately below the shoulder-joint by means of string and plaster-of-Paris. On the unwounded man the splint was retained in position by adhesive plaster. A simple extension was also incorporated. The patient was well satisfied with the splint, and the experiment proved highly successful.

The broken fragments were kept in accurate position, and no daily adjustment of the splint was needed, as had been the case with other types. The patient was able to lie down in comfort while wearing the splint, and it also proved practicable to transport patients treated in this way. On one occasion a soldier wearing a yoke splint rode from Vaarda, on the southern front, to Soddu, a town in the south-west, a journey which took twelve days. A plaster-of-Paris splint modelled on the patient is ideal for fixation of fractures of the neck of the humerus, but it may be very difficult to make when no suitable support can be found around which to fashion it. Fig. 1 shows a back

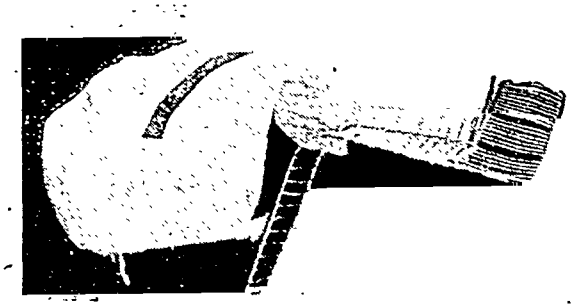

FIG. 1

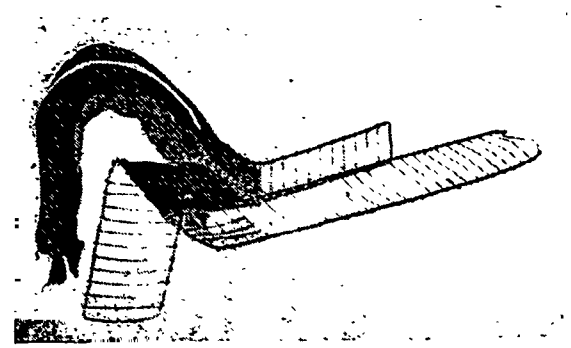

FIG. 2

view of the plaster-of-Paris splint, Fig. 2 a side view. I have also constructed an aluminium splint consisting of two main parts—a yoke and an adjustable support which by means of a ball joint is applied to a steel bow fixed with screws to the yoke. A side bracket which presses against the chest is fixed to the steel bow. An extension is fitted, and a strap keeps the splint in position on the undamaged side. The support can be used equally well on either side.

Advantages

The following points are submitted as the advantages of this improved method of splintage. (1) By means of the yoke the position of the upper arm is fixed in relation to the shoulder girdle; this should lead to complete immobilization and great stability. The yoke prevents the splint from slipping downwards or forwards. (2) The splint permits free movement of the spinal column. (3) If both arms are fractured simultaneously a support can be mounted on each side. (4) Where abduction, but not extension, is required the patient may wear ordinary clothes. Extension can also be very simply incorporated.

"They just growed—like Topsy," is what the National Council of Social Service says of its *Citizens Advice Notes*. But they have grown in a remarkably orderly manner. The revised 1941 edition, clearly indexed, clarifies the large accumulation of wartime legislation on such diverse subjects as war risk insurance, control of noise, reserved occupations, tobacco for the troops. Medical men may be asked to-day: "If the evacuated child I am taking care of falls ill, what should I do?" "What are the best menus for school children?" "What medical arrangements exist for the shelter population?" "What medical facilities are factories bound to provide?" And they will find here all the answers they need. The book is published on a subscription basis, and requests for copies should be sent to the National Council of Social Service, 26, Bedford Square, London, W.C.1. The price is 10s., including supplements.

THE FLOSS SILK LATTICE POSTERIOR REPAIR OPERATION FOR DIRECT INGUINAL HERNIA

BY

RODNEY MAINGOT, F.R.C.S.

Senior Surgeon to the Southend General Hospital and to the Royal Waterloo Hospital, London

This posterior reconstruction operation is not new, nor is it original in any of its essential features. It is in many respects similar to the Gallie method (Gallie and LeMesurier, 1924)—except that here silk is used instead of fascia lata and the pattern of the darn is different—and to the darn-and-staylace procedure which was first recommended and practised with such success by Sampson Handley (1918). In recent years the silk lattice repair has been sponsored by Ogilvie (1937), myself (Maingot, 1940), and others. Since 1934 it has been the method of choice at the Southend General Hospital for all cases of direct inguinal hernia, and we have also employed it for many cases of large oblique inguinal hernia in which the margins of the internal ring and the posterior wall of the inguinal canal have been unduly stretched and the muscles somewhat atrophied.

The final results of this operation when skilfully performed in the manner about to be described have proved so gratifying that they have been almost too good to be true. We have preferred floss silk to other suture material, such as chromic catgut or Pearsall's No. 4 Chinese twist silk. Floss silk is stronger than strips of fascia lata; it remains, of course, unabsorbed in the structures in which it is buried, but it produces no tissue reaction, and eventually becomes incorporated in fibrous tissue. Each strand is composed of many gossamer-like fibrils loosely bound together, and it is not a difficult matter for the fibroblasts to work their way between the fibres and to permeate the new scaffolding with strong white fibrous tissue. The floss silk which we used for our first series of cases was prepared specially for us by Messrs. Arnold and Sons. This was boiled for four hours, and a strand some twenty inches in length was then twisted around a glass rod which was immersed in a hermetically sealed glass tube containing absolute alcohol. Just before use the silk was removed from the tube, dipped into warm normal saline solution, and then thoroughly rinsed in doubly distilled water to rid it of all traces of alcohol. Since the outbreak of the war, however, we have been content merely to boil the strands of silk for some two to four hours before use and then keep them in sterile containers filled with distilled water. We have not immersed the boiled silk in paraffin, glycerin, or other chemical solution before use, as we believe that the employment of these would predispose to tissue reaction, with the outpouring of serum—a most undesirable contingency.

In the conduct of this operation we insist upon the most scrupulous asepsis, haemostasis, gentleness, and tidiness.

Technique of the Operation

The usual incision is a straight one placed parallel to the inguinal ligament and about half an inch above it, and extending from one inch lateral to the internal ring to a point overlying the centre of the external ring. This incision gives direct access to the structures of the inguinal canal, but as it cuts across the lines of stress it sometimes leaves an ugly stretched scar which may be keloid. A more transverse incision, placed in the natural crease in this region, to is be preferred. This starts an inch or so below the anterior superior iliac spine and extends inwards, crossing the inguinal ligament at the junction of the middle and inner thirds, passing to within an inch of the midline, and terminating one and a half inches above the symphysis pubis.

The incision is deepened and the superficial femoral vessels are identified, clipped, divided, and then ligatured with No. 000 plain catgut, after which the subcutaneous tissues are separated down to the shiny aponeurosis. "Tetra" cloths are affixed to the skin margins to isolate the field of operation completely. The upper skin flap is picked up with a pair of toothed dissecting forceps and dissected first upwards to expose a wide area of the aponeurosis and then in a lateral direction for two inches beyond the internal ring. The lower flap is cautiously freed in order to display the inguinal ligament and the attachment of this ligament to the pubic spine.

The external ring should be freely displayed, after which an incision one-half to one inch long is made in the aponeurosis in line with the pillars and an inch or so from the point where they diverge. This incision is lengthened laterally for two inches or so, while medially it cuts across the stretched fibres of the aponeurosis and the lacing transverse bands of the intercolumnar fascia.

The upper leaf of the aponeurosis of the external oblique muscle is clipped with artery forceps and retracted upwards and inwards in order to free it from the underlying cremaster muscle and the arching fibres of the internal oblique muscle and to display the outer border of the rectus sheath as well as the insertion of the rectus muscle from the pubic bone. The lower leaf is then likewise clipped and retracted downwards and outwards to display the recurved medial aspect of Poupart's ligament and its point of insertion into the pubic spine.

In the upper part of the wound the ilio-hypogastric nerve will be seen coursing downwards to disappear in the region of the pubis, while a little below this, lying on the surface of the cremaster, is the ilio-inguinal nerve, which must on no account be damaged during the subsequent dissection.

In the case of a long-standing oblique inguinal hernia with an unusually large sac and a wide neck, the sac is isolated from the cord and the neck of the sac is clearly defined *at* the internal ring, twisted, ligatured, and divided. In the case of a direct inguinal hernia I make it a rule neither to disturb the sac in any way nor to attempt to ligature or invaginate it.

The object of the operation is to produce a solid, flat, uniform fibrous silk sheet to protect the whole of the posterior wall of the inguinal canal and at the same time to provide a suitable aperture for the passage of the cord at a newly reconstructed and more laterally placed internal ring. This is obtained by constructing a lattice with a twenty-inch strand of floss silk threaded on a small curved round-bodied trocar-pointed needle. The cord is lifted upwards and out of the way in the loops of Morant Baker forceps and the suture is introduced by taking a good bite of the deep aspect of Poupart's ligament, first of all at its point of insertion into the pubic spine and then through the lateral tendinous fibres of the rectus muscle at its origin from the body of the pubis.

The end of the suture is not tied at this stage, but is left long and caught up in the jaws of artery forceps. The suture is then continued in a lateral direction—i.e., towards the internal ring—taking first a bite of the ilio-pectineal ligament, then of the recurved edge of the inguinal ligament, including Gimbernat's ligament, then a bite on each side of the cremaster, then of the conjoined tendon, and then back again to the ilio-pectineal ligament and Poupart's ligament. Cooper's ligament is approximated to the innermost margin of the inguinal ligament to obliterate the

crural canal, thereby guarding against the possible subsequent formation of a femoral hernia.

When the crural canal has been efficiently closed from above, the suturing is continued laterally, the conjoined tendon and internal oblique muscle being drawn over to the recurved edge of Poupart's ligament until the internal ring is reached. The stitches are placed almost vertical and side by side, and must not be pulled upon in such a way as to strangle the tissues or to drag the inguinal ligament out of its normal alignment. When the internal ring is approached the cord is drawn firmly outwards and slightly downwards by making traction on the Morant Baker forceps, and the upper and outer margins of the internal oblique are retracted upwards and outwards. The internal ring—or rather the *new* internal ring—should always be reinforced, and in placing it as far as possible from the external ring care should be taken not to compress the cord unduly at its point of emergence from the abdomen. This reinforcement is best carried out as follows:

The floss silk is knotted or locked on the curved edge of the internal oblique, just above the reflected cord. It is carried transversely across above the cord, passed through the internal oblique muscle and locked, and then passed downwards to pick up the edge of the inguinal ligament lateral to the cord. Lastly, three sutures are repeated in the reverse direction, being knotted or locked at each angle so that the emerging cord is buttressed and surrounded by a double ring of reinforcing floss silk. From this point the suture is carried towards the medial end of the canal with a wider transverse, picking up the external oblique muscle or conjoined tendon and anchoring this structure to the inguinal ligament.

At the extreme medial point of the canal the free end of the suture, after once again passing through Gimbernat's ligament, through the periosteum of the pubic spine, and through the dense fibres of the origin of the rectus muscle, is tied to the end which was left long and is steadied with artery forceps. The edges of the aponeurosis of the external oblique are then sutured behind the cord, using a continuous suture of No. 00 twenty-day chromic catgut, thus placing the cord subcutaneously. The wound is now closed.

In order to avoid the formation of dead spaces in which serum may collect and thus predispose to infection, stitch abscess, and so forth, the subcutaneous tissues and the fasciae of Scarpa and Camper on each side of the wound are evenly and accurately approximated with a series of closely placed interrupted sutures of the finest plain catgut. The skin edges themselves are closed with vertical mattress sutures of deknatel or fine silk and a few Michel clips, after which a simple gauze dressing is applied, this being kept in position by means of a broad piece of flexible elastic strapping. The Michel clips are removed at the end of forty-eight hours and the skin stitches on the fourth day. It is most important to keep the patient in bed for a period of not less than three weeks.

Conclusion

It will thus be seen that much importance is attached to strengthening the whole of the posterior wall of the inguinal canal, especially its medial aspect, where recurrence is so prone to occur, and to closing the crural canal from above, thereby preventing the possibility of a subsequent femoral hernia such as is sometimes seen following even a most thorough operation for direct inguinal hernia.

Clinical Memoranda

Herpes Zoster with Muscular Paralysis and Disturbance of Sensation

In the *Journal* of February 15 (p. 234) Drs. Carter and Dunlop drew attention to instances of paresis following upon herpes zoster. A case of like nature under my care is of interest on account of the severity and wide distribution of the motor and sensory disturbances which have accompanied the herpetic symptoms.

CASE REPORT

The patient, a man aged 68, was apparently vigorous and healthy, with no history of previous illness of importance. The Wassermann reaction was negative. In October, 1940, he had an attack of pain in the neighbourhood of the left hip and thigh and the outer aspect of the left leg; this was accompanied by an eruption of herpetic vesicles on the left buttock and by a simultaneous foot-drop on the left side. The general symptoms were slight, and he was able to continue at fairly laborious work. The pain was troublesome for about two months and then gradually subsided, so that at the end of three months it amounted to little more than discomfort. The pain was not aggravated by bending down and did not interfere with his work, and was thus unlike that usually present in sciatica.

The case came under my observation on February 11, 1941, four months after the onset. On examination the scars of a few herpetic vesicles were present on the inner part of the left buttock. All the muscles of the left thigh and leg exhibited a generalized wasting, moderate in grade, with the exception of the anterior tibial group, where the wasting was extreme. The tibialis anticus, extensor longus digitorum, and extensor proprius hallucis were paralysed, with reaction of degeneration and resultant complete foot-drop. No paresis was observed in other muscle groups. Both knee-jerks were active; the left ankle-jerk was diminished, and the right ankle-jerk still more so, being barely perceptible. Hyperaesthesia was present on the outer and anterior aspects of the left leg, with patches of hyperaesthesia along the anterior and posterior borders of this area. Hypo-aesthesia of higher grade, involving both pin-prick and light touch, was also present on the dorsum of the left foot, extending from the ankle-joint to the root of the toes. There was no disturbance of sensation in the neighbourhood of the site of the herpetic vesicles on the left buttock.

On March 11, one month from the previous examination and five months from the onset, there was distinct evidence of amelioration of the symptoms. Tonus was now present in the anterior tibial group of muscles, assisted by faint voluntary power in the peroneus tertius, which had previously been inactive. The hypo-aesthesia of the leg had been replaced by hyperaesthesia, particularly in the form of tingling on percussion. The hypo-aesthesia of the dorsum of the foot was unchanged.

COMMENTARY

The motor and sensory symptoms do not correspond to the distribution of peripheral nerves, and they have not the character of a root syndrome. The paralysis of the anterior tibial muscles corresponds to a lesion of the L4 and L5 segments, the sensory changes in the leg and foot to the S1 and S2 segments, and the herpetic symptoms to the S3 segment. Taken together the features are those of a diffuse affection of the cord, almost entirely on the left side, involving both the motor and sensory regions of the lower lumbar and upper sacral segments and the root ganglion of the third sacral. Such widespread symptoms are in accordance with the diffuse pathological changes described in Lhermitte, as quoted by Carter and Dunlop.

Notwithstanding the severity of the paralysis of the anterior tibial muscles the evidence of regeneration leads to the expectation of some measure of ultimate recovery.

Physician for Orthopaedic Diseases, Royal Hospital, Sheffield; Medical Director, Edgar Allen Institute, Sheffield.

OSTERMILK IN WARTIME

When breast feeding is out of the question, the importance of dried milk needs no emphasis. It is imperative that supplies should be instantly available to infants who really need it. As part of our organisation to retain adequate distribution of Ostermilk, we have instituted a campaign in the national press. Mothers are given reminders on the following points, which have always been part of our policy :—

(a) Not to buy Ostermilk for household use.
(b) Not to hurry the infant on to the bottle, but to persevere with breast feeding.
(c) If bottle feeding becomes necessary, to use Ostermilk first as a supplementary feed.
(d) Not to give more than the prescribed amount.
(e) Not to prolong bottle feeding, but to begin a mixed diet about the sixth month, as generally advised to-day.
(f) To resist the temptation to "hoard" Ostermilk.

It is hoped by this means to avoid unnecessary demands upon distributors' resources, and thus ensure that no infant who has real need of the benefits of Ostermilk shall be denied.

Ostermilk No. 1 modified; No. 2 full cream; both at 2/6 per 16 oz. tin.

GLAXO LABORATORIES LIMITED, GREENFORD, MIDDLESEX. BYRon 3434

FAREX takes care of the food factors

whatever the diet . . . whoever the patient

The achievement of Farex is that it combines, in a single highly digestible food, carbohydrate and protein with declared amounts of the minerals and vitamins physiologically necessary to health. In Farex, the finely milled wheat-flour, oatmeal and maize, are blended with wheat-germ and yeast (potent sources of vitamin B_1., essential to complete carbohydrate metabolism, long anticipating contemporary emergency measures). Iron, calcium and other minerals are added to maintain a normal blood-picture: extra vitamin D secures a helpful calcium intake: tissue repair and growth, and a strong resistance are encouraged by the addition of vitamin A.

This known content of Farex is of great value in view of the present difficulty of assessing the intake of any particular food factor from haphazard war-time diets. As a nutritionally safe weaning food, as a balanced diet for invalids, and as a supplementary basis for all whose diet needs a computable intake of all the principal food factors, Farex stands alone. In ½ lb. and 1 lb. cartons.

FAREX 3-CEREAL, MINERAL-VITAMIN FOOD, READY-TO-SERVE

PRODUCT OF THE GLAXO LABORATORIES

GLAXO LABORATORIES LTD., GREENFORD, MIDDX. BYRon 3434

'Elastoplast' Extension Plaster for Skin Traction

FIRM and more lasting adhesion is obtained by weaving or interlacing longitudinal strips of 'Elastoplast' Extension Plaster with standard 'Elastoplast.'

The first turn of the 'Elastoplast' Bandage (at the top of the thigh) is applied *over* the extension strips, the next turn passes *under* them, and the succeeding turns pass alternately over and under. By this means the pull is distributed evenly over the entire area of the limb.

'Elastoplast' Extension Plaster is made to stretch *crosswise* instead of lengthwise, thus giving the necessary resistance to traction, whilst the plaster can be stretched firmly around the limb.

These plasters are available in widths of 2, 2½, 3 and 4 ins. by 1, 2 and 3 yds. long, and are obtainable through your usual surgical supplier.

'ELASTOPLAST' BANDAGES AND PLASTERS ARE MADE BY T. J. SMITH & NEPHEW LTD., HULL

Reviews

THE STATE AS AN ORGANISM

The Behaviour of Nations. An Essay in the Conduct of National Organisms in the Nutritional Field. By Morley Roberts. (Pp. 180. 12s. 6d net.) London: J. M. Dent and Sons, Ltd. 1941.

Mr. Morley Roberts has long been known as a distinguished exponent of the application of biology to sociology. In *The Behaviour of Nations* he is a Sherlock Holmes to Dr. Watson's "behaviourism." He modernizes the tradition he admires of Hobbes and Machiavelli (also of Malthus, whom he does not, however, mention) into biological language and comes to some depressing conclusions. Like Hobbes, he visualizes the State as an organism, though as a lowly invertebrate and not as a leviathan. Although Lord Samuel in his *Belief and Action* strongly opposes any such biological conception, it has its appeal to the biologist who is prepared to accept Mr. Roberts's application of the internal tensions and mutual adaptations necessary in all metazoa to similar conditions obtaining between individuals or States. He can appreciate the analogy of an organism seeking its sustenance in a nutritional field, wherein hunger transcends all law. We can all see that now man has sold himself to the machine he must feed it; has not the invention of the internal combustion engine reorientated the whole field of international politics? We are all prepared to admit that men collectively are apt to behave less ethically than as individuals, and we have all been appalled at the return to barbarism with its accompaniments of treachery and lying. So far author and reviewer are at one. When, however, Mr. Roberts accuses people of acting as if evolution had come to an end we might retort that on his view of evolution as stated here it has no better fruits in store. Surely a static attitude. He sees Nature red in tooth and claw to the end of geological time; but, though we must admit the recurrent danger that lower civilizations are to the higher ones who have learned to value other things more than war, we are equally impressed by the development of the heptarchy into the present unity of Britain.

Mr. Roberts entirely denies the validity of morals in international relations, though recent events might give pause to that conclusion. Yet even with him morality will keep "breaking through." Thus he admits (p. 66) that "morality arises from the evolutionary necessity that . . . nations themselves must learn . . . to put up with each other and refrain, so far as their tropisms and instincts permit, from acts harmful to social life." Again (p. 63), "I begin to think that nations will presently look with . . . dislike on the practice common in some countries of insulting aliens," for (p. 62) "there is little doubt that any nation feels deeply, whatever it may say, if it is aware that no one willingly associates with it." While maintaining that science must work by the driest light, and without passion, "dismissing mere prejudice in favour of cold observation and bloodless logic," Mr. Roberts nevertheless directs shrewd if not angry blows at those who disagree with him, and especially at politicians who ignore his gospel. With D. H. Lawrence he regards instinct as infinitely more likely to disclose the right course than the intellect. Stronger, yes; but safer? This curious tendency of intellectuals to denigrate the intellect in books presumably written for intellectual readers is an interesting symptom of this unreasonable age.

This book completes the trilogy starting with *Warfare in the Human Body* and continued in *Bio-politics*, flanked by *The Serpent's Fang* and *Evolution and Malignancy*: a remarkable series, even if not gaining universal acceptance. For Mr. Morley Roberts's writing never lacks distinction, and in the present book he rises to almost lyrical heights (as befits an old sailor) on the influence of the sea on history, while the chapter on mass migration is full of fascination. His study of national temperaments, particularly of German claustrophobia, is of great topical interest. No doubt at the present moment his astringent philosophy may serve as an antidote to dangerous complacency, but it is interesting to contrast his bleak pessimism with the tempered optimism of *Man on his Nature* by Sir Charles Sherrington, whose status as a biologist Mr. Roberts will readily admit.

CEREBROSPINAL FEVER

Cerebrospinal Fever. By Denis Brinton, D.M., F.R.C.P. (Pp. 164. 8s. 6d., plus 6d. postage.) Edinburgh: E. and S. Livingstone. 1941.

The treatment of cerebrospinal fever has been perhaps more completely revolutionized within the past few years than that of any other disease. Not only has chemotherapy entirely replaced serum treatment—whereas in some other infections the two are still combined—but even spinal drainage by repeated lumbar puncture is now often looked upon as superfluous. At the same time opinion has changed on certain aspects of the epidemiology of this disease. Its prevalence is so irregular that many practitioners have had little experience of it. These are three good reasons why a fresh account of the whole subject should be published, and Dr. Denis Brinton furnishes this in a modest volume entitled *Cerebrospinal Fever*, which deals with the disease from every aspect, but most fully with its clinical diagnosis and treatment.

The forms of meningococcal infection described include not only meningitis of different types, but both the fulminating and chronic forms of meningococcal septicaemia. The instructions given for treatment are clear and dogmatic. It is first laid down that every case should be treated in hospital, and the practitioner is very properly warned that if he begins sulphonamide treatment before the admission of the case to hospital the amounts given should be stated, and a specimen of cerebrospinal fluid secured before chemotherapy has rendered a bacteriological diagnosis difficult or impossible. The scheme of dosage adopted by Banks is recommended, and sulphapyridine is the drug chosen, sulphanilamide only being given for a short period if the former causes vomiting. This is orthodox practice, and if the concentration in the cerebrospinal fluid necessary to secure a given therapeutic effect is lower in the case of sulphapyridine that is an adequate explanation of any greater therapeutic efficiency which this drug may possess, but the reiterated statement that sulphapyridine is less toxic than sulphanilamide must be disputed. It is recommended that a blood count should be done after 30 grammes have been given; this is a sensible rule for guarding against the remote possibility of granulocytopenia. Not only is drug fever described, but the rash accompanying it is the subject of the only illustrations in the book, of which there are four. This complication occurred in 16 of a series of 46 cases observed by the author. It is so often mistaken for a recrudescence of the disease, and consequently treated in the opposite of the correct way, that an emphatic warning against this error would be a useful addition.

In a discussion of pathogenesis, Le Gros Clark's studies on the spread of material from the nasal mucosa to the base of the brain are disregarded; it is by no means as certain as the author would have us believe that meningococcal meningitis is haematogenous. No attempt is made in discussing epidemiology to explain the still mysterious aspects of this subject, and the current teaching that carriers should not be sought for is accepted.

DISEASES OF THE CHEST

A Practical Manual of Diseases of the Chest. By Maurice Davidson, M.D., F.R.C.P Second edition. (Pp. 576; illustrated. 42s. net.) Oxford Medical Publications. London: Oxford University Press. 1941.

The busy practitioner, or the student working for a higher examination in medicine, requires something more than his undergraduate library, but is usually unwilling to strain his purse, bookshelf, or mind with cumbersome manuals of special subjects. He is interested in practice rather than in theory, and especially in modern developments in medicine. The second edition of *A Practical Manual of Diseases of the Chest*, by Dr. Maurice Davidson, is well planned for this purpose: it is well illustrated, liberal use has been made of reports of the author's own cases, and its length is less than 600 pages.

Most textbooks which are original, and not merely a copy of others, are easy to criticize in matters of detail, and this is no exception. For instance, it seems unfortunate that sulphapyridine in the treatment of pneumonia is dismissed in twenty lines, although two and a half pages are devoted to serum therapy; and although the dangers of agranulocytosis are stressed, there is no mention of the commoner forms of idiosyncrasy which frequently interfere with sulphapyridine treatment. Many physicians would disagree with the statement that atropine in doses of 1/50 grain is urgently indicated in acute pulmonary oedema, and those in practice would be more interested in the simpler methods of withdrawing air from a spontaneous pneumothorax than with an artificial pneumothorax apparatus or trocar and cannula.

Other minor criticisms could be made, and yet this book should be a useful addition to any medical library; it contains much well-organized information and will be of value to all those interested in clinical medicine.

BOMBING AND PLANNING

The Lesson of London. By Ritchie Calder. (2s. net.) Searchlight Books, No. 3. London: Secker and Warburg.

Start Planning Britain Now. A Policy of Reconstruction. By Ritchie Calder. (1s. net.) London: Kegan Paul, Trench, Trubner and Co. Ltd.

Ritchie Calder is an accomplished journalist with a passion for finding out the truth about all and sundry matters and for setting down in print the truth as he sees it, no matter how unpalatable it may be to those in authority. His fearless disregard of personalities and powers, coupled with a capacity for acute observation and shrewd deduction, well fit him to tell the story of London under aerial bombardment. He describes again the tragic and fatal muddle in the dock area last September, and the heroic efforts of the East London clergymen to counteract the harm of official inertia and lack of imagination. He has penetrating things to say about evacuation, the care of the homeless, feeding centres. But we question the justice of his generalization, "Family doctors saw in the shelter clinics a threat to their fees," and suspect this to be an argument from one or two particular cases to the general. And in view of the shelter conditions described by Mr. Calder they would not seem to be (whatever they might become) ideal for clinics where "incipient diseases could be discovered and checked." Nor is it clear why, because of shortcomings and dislocation of practices, the "State should intervene and [that] there should be a complete and salaried medical service." Would Mr. Calder advocate the same remedy for his own profession of journalism? Apart from these points of criticism, his book is a useful war document, and deserves to be widely read.

Start Planning Britain Now may best be described as a series of vigorously written notes on the chief aspects of the problem; it is a compact "planner's guide." In just over two pages Mr. Calder plumps for a "salaried medical service," and in this, as the columns of the *Journal* have shown during the past year, he has the support of many doctors. This small book of sixty-three pages has much in it that is provocative and stimulating.

Notes on Books

A little book of some sixty pages, *Administrative Notes for Royal Army Medical Corps Officers*, by Major J. COHEN, is published by Gale and Polden, Ltd., of Aldershot, at 1s. 6d. There is so much to be learnt in so short a time by R.A.M.C. officers young in the Service that everything possible must be done to help them. The practice of "spoon-feeding" is to be condemned in normal circumstances, but the circumstances of to-day are abnormal. These methods of training are bad; the newly joined medical officer must find out things for himself. Every scrap of essential information will be found in official manuals, handbooks, and pamphlets, which are issued to all concerned. Abstracts and notes should be compiled and kept for ready reference in the field by the officer himself, who should be discouraged from relying on pabulum prepared by others. The pamphlet under review was evidently prepared many years ago, and no attempt seems to have been made to keep the material up to date. We have not space to point out all the inaccuracies and omissions. The war establishment of a field ambulance is incorrectly given; no mention is made of the light field ambulance. Little is said about message writing or about armoured or mechanized formations. The road spaces given are pre-war, and nothing is said about the scatter and dispersal layout of medical establishments. It is a pity that the data were not checked, criticized, and corrected by a senior serving officer before publication.

Preparations and Appliances

LOCAL ANAESTHETICS

"Anethaine" brand of butethanol (Glaxo Laboratories, Ltd.) is stated to be "an extremely powerful local anaesthetic chemically allied to procaine and identical with a widely used substance hitherto only produced abroad." The chemical constitution is stated to be 4-butyl-amino-benzoyl-dimethyl-aminoethanol hydrochloride. It is about twice as toxic as cocaine, but has ten times as powerful a local anaesthetic action. It can penetrate mucous membrane and therefore can be used as a surface anaesthetic in the eye, nose and throat, urethra and rectum. The vendors advise that it should not be injected subcutaneously.

"Sevicaine" brand of procaine hydrochloride (Glaxo Laboratories, Ltd.) is issued as a 1% solution suitable for infiltration anaesthesia and as a 2% solution with 1 in 60,000 adrenaline hydrochloride for terminal and regional anaesthesia.

IMMUNIZATION AGAINST SCARLET FEVER

Lederle Laboratories announce the issue of an improved streptococcus toxin for use in immunization against scarlet fever. Unpleasant reactions following administration are claimed to be greatly reduced by substitution of peptone in a concentration not exceeding 1 per cent. of blood or serum in the preparation of this toxin, without loss of immunizing properties. The product is marketed in this country by Chas. F. Thackray, Ltd., Leeds.

GENTIAN VIOLET JELLY

Allen and Hanburys, Ltd., have placed on the market "Geviflex," a gentian violet jelly for application to burns, etc., as an alternative treatment to tannic acid. It contains 2% gentian violet with phenyl mercuric nitrate 1/3,000. The latter is a germicide of low toxicity. "Geviflex" is packed in tubes containing 1½ oz. and 5 oz. at 1s. 11½d. and 5s. 10d. each respectively, including purchase tax.

BRITISH MEDICAL JOURNAL
LONDON
SATURDAY MAY 24 1941

TRAUMATIC EPILEPSY

Once again gunshot wounds of the head are causing an increase in the number of epileptics. Neurologists are debating prognosis, neurological surgeons are discussing the safest treatment of damaged brain, and medical boards are thrashing out the old questions of causation and attributability. But in this war cerebral gunshot wounds are a civil as well as a military problem, and the management of traumatic epilepsy will be the concern of many. This is, therefore, an apt moment for publishing Ascroft's report[1] on the incidence of epilepsy occurring after gunshot wounds inflicted in the last war. His analysis of the Ministry of Pensions records of 317 cases of gunshot wounds severe enough to lead to the granting of a pension shows that as many as 34% of the cases are known to have developed epilepsy; as they were all pensioned after appearing before several medical boards the evidence is convincing. Attacks now considered to be on the borderland of epilepsy would not be included in this total, so that the figure quoted is not an overstatement. Epilepsy developed in 24% of patients with gunshot wounds involving only the scalp, while twice as many had fits after tearing of the dura with cerebral laceration. These figures are much higher than those recorded by Wagstaffe,[2] who, after a similar survey of casualties from the last war, found epilepsy in only 1.6% of cases suffering from scalp wounds alone, and in 19% of those with dural penetration. This may be compared with the corresponding figures of Villaret and Bailby[3] of 6 and 16% in 500 cases. There are reasons for the discrepancy. Ascroft's group included only patients who, having survived for more than four years, were granted a pension, and observations were made over a follow-up period of twenty years, whereas the other authors reported their findings soon after the injury and on less highly selected material. There is no doubt that many attacks later shown to be epileptic were not included.

Thus we have the hard fact that epilepsy develops in a third of the cases with an open head injury severe enough to warrant a pension, and in nearly half of those with dural penetration. But this result is not so bad as it appears superficially, for in one-third of the patients the epilepsy was transitory. The first fit occurs most commonly within fourteen days of the injury—often within a few hours—and patients who develop these immediate post-traumatic convulsions have a reasonably good prognosis, for their epilepsy tends to be short-lived. This observation is contrary to the general belief, supported by the figures of Feinberg[4] and others, that traumatic epilepsy most often appears between six and twelve months after the injury has been sustained. It agrees, however, with the observation of Symonds[5] that if the minor attacks which occur within a few days of the cerebral insult are recognized the prognosis in traumatic epilepsy is far from gloomy. On the other hand, Ascroft's figures and those of other workers show that when the fits begin more than a year after the injury the prognosis is usually bad. Feinberg, on the basis of 47,000 insurance cases of head injury, including the most trivial, found undoubted epilepsy in less than 1 in 1,000. But in this war we have to deal with far more severe injuries than occurred in most of his series. Aldren Turner[6] and Wagstaffe both found that parietal injuries were most likely to be followed by epilepsy: in this they are supported by Ascroft, for half of his cases with injury to the Rolandic area developed fits. Even here the fits are not necessarily Jacksonian; only a third of the total had a focal onset, and most of these presumably were generalized grand mal attacks. Symonds found Jacksonian epilepsy in only 7% of his series, and it is well recognized that focal epilepsy is commonly idiopathic. As Jefferson[7] pointed out, the belief that Jacksonian and traumatic epilepsy are synonymous and reversible terms is untrue in the great majority of cases.

Ascroft's valuable analysis is not entirely discouraging. It does give us hope for better results in the future. Interference with buried fragments, sepsis, and delayed healing all greatly increased the incidence of epilepsy, and with the experience and materials at our disposal to-day we can surely expect great improvement in this respect. Lennox[8] has shown that many traumatic epileptics come from families with a tendency to this disease, and it now seems that the difference between traumatic and idiopathic epilepsy is one of degree only. When modern surgery has done its best to minimize the risk, the fact remains that in predisposed subjects a head injury tends to unmask the predisposition. The ultimate control of the disability is linked with an understanding of the pathogenesis of idiopathic epilepsy, which is at present beyond our grasp.

DEATHS BY VIOLENCE

In England and Wales in 1937 nearly 23,000 persons died violent deaths. None of these deaths was due to war, but a study of this section of mortality has a certain interest at the present time; consideration of the gas-oven suicide or the overlaid infant has a wholly different atmosphere from that which attaches to deaths from high explosives. It was from this point of view that Prof. M. Greenwood and Drs. W. J. Martin and W. T. Russell presented to the Royal Statistical Society on April 15 a paper in which they surveyed the statistics of deaths by violence during the century of registration. In the seventeenth century deaths by violence accounted for not quite 1% of all deaths, but in 1938 in the County of London 4.5% of the deaths were so designated. This does not necessarily mean that the modern Londoner is more likely to be murdered: it simply means that in the past "natural" deaths were more frequent, and that death-dealing machinery was less

7 *Medical Annual*, 1934.
8 *Arch. Neurol. Psychiat.*, 1940.

in evidence. No precise comparison can be made, however, of the rates of mortality even since 1837, when registration of deaths became a national concern, because there have been so many changes of classification—for example, in 1861 deaths from intemperance and from deprivation of food were no longer classed as violent, and in 1901 deaths from food poisoning, injury at birth, and drug addiction were removed from this category, though deaths from privation and food poisoning were restored in 1911. Taking all forms of violence the standardized rates per million in the decade 1861-70 were 1,169 for males and 349 for females, and in the quinquennium 1931-5 these had fallen to 648 and 260 respectively. Taking rather different periods but with the same interval, in the years 1863-70 the male death rate per million due to accidents in coal-mines was 96, to vehicles 195, to drowning 214, and to burns, scalds, and suffocation 182, while the corresponding figures for 1931-8 were 40, 260, 58, and 49. The female death rate in these categories is smaller (except for burns, scalds, and suffocation, where it is equal to that in the male), but the trend is the same. It was in 1896 that the first deaths—those of one male and one female—were registered as due to motor-cars, and the first deaths due to motor-cycle accidents were those of two males in 1902. Infant deaths from overlying were examined by the Registrar-General in 1890, when he found that one-fifth of such deaths occurred during the first month of life, that 60% of them occurred during the winter six months, and that these deaths were twice as numerous on Saturday nights as on any other night of the week. The assumption that the drunkenness of the parents was responsible for the weekly peak cannot be wholly justified. Many of the deaths certified as overlying were probably due to pneumonia.

The authors devoted the greater part of their paper to the question of suicide, of which there has been a large increase during the twentieth century, especially among women. The standardized suicide death rate per million for females in 1901 was 46, and it kept within the forties until 1924, except for the two war years, 1916 and 1917, when it fell to 38 and 35; but in 1925 it went up to 50, and has never fallen below that figure since then, even reaching 65 in 1933. Suicide rates are low among nuns and teachers other than music teachers (though what the rate is amongst music teachers and whether it shows any significant difference was not stated), and high among the wives of unoccupied males. Suicide is relatively more frequent among the black-coated class. The authors gave a table based on the figures for the period 1930-2, which suggested that in males in professional occupations the highest rates were in the legal profession, and then, in diminishing numbers, among dental practitioners, officers in the Forces, authors and journalists, and physicians and surgeons; while in the class of manual workers the highest rates (but on a lower level than generally in the professional classes) were among barmen, costermongers, newspaper sellers, and dock labourers. As for the methods of self-destruction, the most striking feature is the increasing preference for the gas oven. In 1936-8, 31.5% of all male suicides and 42.2% of all female made use of coal gas, which was not readily accessible for this purpose before the turn of the century and only became "fashionable" after the last war. The conveniences of modern life are factors of as much importance in the suicide rate as its stresses and strains. War has hitherto had the effect of lowering the number of suicides, though what the effect may be of the present mass terrorism cannot yet be judged. Homicide has steadily decreased. The death rate per million due to murder and infanticide, which in 1863-70 was 12.5 for males and 11.1 for females, has fallen consistently, until in 1936-8 the figures for the sexes were 2.0 and 3.3.

On the whole, violent deaths were diminishing, though the decline was retarded by the multiplication of instruments of violence, which may be expected to continue. "Unless the experience through which so much of the world is now passing excites such a passionate hatred of the air that aeroplanes are classed with opium and proscribed, civil aviation may well compete seriously with motoring as a cause of death." But Prof. Greenwood added that such proscription would be a fantastically improbable display of herd intelligence.

SCABIES AND IMMIGRATION

Scabies is a disease which periodically draws attention to itself because of the gross amount of irritation it causes in certain communities. It is difficult to control in the herd, and difficult to prevent in the individual. In two recent articles Dr. Reuben Friedman[1] traces the history of scabies in the United States. The early history is conjectural, but it is probable that the disease was introduced into the American colonies by the pioneer colonists. That the condition was prevalent enough to be a gold-mine for prospecting quacks and less scrupulous qualified practitioners is shown by the frequency with which advertisements for so-called cures appeared in philosophical and scientific magazines. Even Benjamin Franklin, one of the greatest of scientists, did not escape entirely from association with such practitioners; his mother-in-law, the widow Read, advertised frequently in the *Pennsylvania Gazette* a cure which in ointment form had a pleasant smell and could be used "without the least Apprehension of damage even to a Sucking Infant." There is no indication whether the price of two shillings an ounce was extortionate or otherwise, nor does there seem to be any corroboration of the widow's claim that this quantity was "sufficient to remove the most inveterate Itch and render the Skin clear and smooth." This advertisement appeared in 1731, and in later years there was less emphasis on the prevalence of scabies. From records appearing in the earlier medical journals it is apparent that scabies made up only from 0.3 to 2% of skin conditions seen in large general hospitals. In other words there was no epidemic. Towards the middle of the 'eighties the proportion of cases of scabies seen at these hospitals rose steeply, and, what was more significant, skin specialists began to see such patients in their private practice. Greenough, in 1886, commented on this frequency at the Boston Dispensary and ascribed the increase to three factors—contagiousness, the fact that the disease was self-limited, and the free circulation which existed between cities and country districts. In 1889 White ascribed the prevalence to an increase in the crowding of operatives in the factories of large cities, and to the growing number of commercial travellers. The true cause of the increased incidence—namely, the effect of immigration—was given by White in the following year, and he then stated that

[1] *Ann. med. Hist.*, 1940, 2, 393, 401.

the means of prevention were simple. As he says, "If all immigrants were carefully inspected at quarantine and every one affected were submitted to a three-hours treatment, as in the quick cure of foreign military hospitals, we might before long reduce the prevalence of scabies to its former low percentage." Despite the sanguine view taken by White the expected decrease did not come until very much later. Other authors—for example, Hyde and Montgomery in 1904—speak of the increase in immigrants. Stelwagon says that the introduction of a few immigrants from a foreign country into an unaffected centre of population often gave rise to a skin condition which the local inhabitants were quick to stigmatize with the nationality of the immigrants. Hence there arose terms such as "Italian itch" and "Hungarian itch." Hyde, in 1905, stated that "the fruitful and unfailing source of scabies in North America is Europe, and in particular the crowded residents of the Old World." He believed that contributory causes were the aggregation of human beings which occurred at the holding of a great fair, and also war. At the present time we are spared some of the effects of immigration, but this country is in the throes of war; the effect of heavy bombing brings people together in much less favourable conditions than exist during large fairs or exhibitions. There are definite grounds for believing that the authorities are succeeding very well in treating cases of scabies as they arise, but the disease is again a major epidemiological problem. It would be bold to state that excessive prevalence can be prevented, and in these times it is useful to go back to the old records.

BRONCHITIS AND OTHER INFECTIONS IN WAR

It is a truism to say that deaths from violence are not the only, and not necessarily the largest, contributions to war mortality. The present conflict is likely to be no exception to the rule, although, with greater knowledge and much more effective methods of control than before, the emphasis may well fall on very different causes of death. Small-pox, for instance, may hold fewer fears for us, though it is no source of complacency to know that many infants are still not vaccinated. The enteric fevers have already been kept in check, in spite of damaged water supplies. On the other hand, there is some indication of the expected rise in tuberculosis. In reply to a question recently addressed to him, the Minister of Health stated that the number of deaths from all forms of tuberculosis in the second quarter of the year was 7,116 in 1940, compared with 6,863 in 1939 and 6,973 in 1938. Some control, by no means full, can be assumed here. In the last war there was the influenza pandemic of 1918-19. It fell equally on the sanitarily just and unjust, as the Registrar-General observed, and we are to-day very little if at all nearer averting its development on a major scale. So far we have escaped, and the course of the common infectious diseases in Great Britain has, too, been very favourable. Cerebrospinal fever, invariably a camp-follower, is the one exception, with an incidence in 1940 of at least ten times the normal—though with modern methods of treatment it will have a lower mortality. A close watch is no doubt being kept in official quarters on these and other pointers to the state of the public health. It is not so easy for those outside Government Departments to study the trends of disease and mortality and thus to draw attention to any untoward developments. There is delay, more perhaps than would seem inevitable, in publishing the national records. The Registrar-General's annual report for 1938 is still the last available. There are, too, the vast changes in the distribution of the population due to evacuation and conscription, and no one without access to official records can assess their influence.

One record that has, fortunately, been issued with regularity is the Registrar-General's weekly report, which offers at least two features of interest—namely, the notifications of infectious diseases in the country as a whole and in different parts of it, and the causes of mortality in the County of London. Using the latter data, Prof. R. M. F. Picken contributed in last week's *Journal* (p. 744) an interesting study of the mortality attributed to bronchitis in London since the war. He observes that though the total mortality in 1940 (excluding for obvious reasons deaths from violence other than suicide) was not appreciably different from the average of the previous ten years (44,548 deaths against an average of 48,805 in 1930-9), there was a very large increase in deaths debited to bronchitis (4,675 against 1,915). Two questions present themselves: How far is this rise real? and, How far is it attributable to war conditions? The main case for doubting its reality lies in the change that has taken place in tabulating causes of death when more than one appear on the certificate; arbitrary rules of tabulation gave way in 1940 to acceptance so far as possible of the certifying practitioner's order of preference. This change would be likely to add to the figures for bronchitis and to reduce those for heart disease, and Prof. Picken's study of the relevant figures leads him to the conclusion that a large part of the rise in bronchitis mortality is in fact fictitious. Part, on the other hand, seems certainly to have been genuine, and cannot be ascribed to influenza, which has been relatively absent. Its incidence followed the normal seasonal course, so that, in so far as there was a real increase in mortality from bronchitis in 1940, most of it was in the early part of the year—before resort to shelters became either necessary or frequent. A severe winter was the most noticeable feature of the period. In 1941 the cold spell was less severe and came later in the year; the peak of bronchitis deaths was also later. Prof. Picken's conclusion, therefore, is that, though the black-out may have increased the influence of ill ventilation which always accompanies cold weather and favours respiratory infection, it is most probable that the observed increase in mortality from bronchitis was due mainly to the exceptional weather conditions and not to special circumstances arising from the war.

FUNCTIONAL VASCULAR DISTURBANCES IN THE BRAIN

The study of what may be called the vascular factor in brain physiology and pathology has had its vicissitudes. The triumphs of staining methods for nerve cells and fibres fascinated brain histologists in the pursuit of still more refined ways of exposing the peculiarities of brain tissue itself, while the study of the physiology of the neuron, aided by technical developments in electrophysiology, has proved equally seductive to the experimental neurologists. Both kinds of technique had the advantage that they could be followed to a considerable extent *in vitro*; while the problems of the vascular supply to the brain, partly because they implied an intact animal, had, so far as possible, to be approached functionally, and so were for a time relatively neglected. This tendency in research was aided by the declination of some physiologists that the blood supply to the brain, unlike that of other organs, had no nervous control of its own, and so could not be conceived as being dynamically related to brain function in the way that might by analogy have been anticipated. Of recent years, however, the reverse opinion has been widely accepted, and physiologists and pathologists alike have turned to variations in the blood supply to local areas of the brain to throw new light on its activity. An example is a recent

paper of Helfand's[1] on the effect of trauma on animal brains. He goes so far as to suggest that the variations in vascular supply to different regions of brains injured by the dropping of weights on the skull may depend on the transmission of local vascular reflex disturbances travelling by the meningeal vessels to the superficial layers of the cortex. In this way, it is suggested, it may be possible to explain the occurrence of local disturbances varying from complete absence of visible capillaries to local engorgement accompanied by diapedetic exudation, in contrast to the relative uniformity of capillary patterns throughout the normal cortex. Such observations were made more possible by the use of the benzidine stain introduced by Pickworth. Brain histology has for many years been rather neglected in this country except in one or two laboratories, and it is encouraging to find a technical advance which is indigenous.

The relation of such observations on the normal vascular pattern to the understanding of mental disorders is another question. Not many will be willing to go as far as Pickworth,[2] who enthusiastically declares that "it is believed that the exact locality within the brain of such vascular effects, duly considered in relation to duration and development growth, determines the type of mental disorder and defect." This seems to contradict the existing knowledge of lack of association between locality of lesion and type of mental symptom; nor will many agree that "consciousness is made up of tensions, throbs, pangs, flushes, suffocations, etc.," and nothing else. But such enthusiastic notions stimulate us to consider that the capillary flow may warrant more attention than it has received hitherto. It has also been shown that the function of a particular region of the brain is accompanied by capillary dilatation there—for example, in the olfactory lobe of a rabbit when its smell apparatus has been stimulated, and in the occipital lobe as the result of visual activity. In pathological conditions more may be attributable to capillary obstruction in some instances than to direct toxic action on nerve cells. In tetanus and chorea, for example, thrombi are found in the vessels. It has been argued that the anoxaemia resulting from endarteritis is a cause of the parenchymatous change in general paralysis, and it has even been maintained by Hutton[3] that the endarteritis itself, so far as the smaller vessels are concerned, is a result of anoxaemia. Vascularization means, of course, oxygenation. It seems more and more likely that the physiopathology of the brain and the symptoms of the so-called symptomatic psychoses are ultimately matters of oxygen supply to brain cells. Even the constitutional psychoses may depend on episodic or chronic inadequacy of oxygenation of individual cells, and the effects of the new convulsion therapy may depend on the promotion of capillary dilatation.

SURGICAL ANTISEPTICS TO AVOID

The war brings with it fluctuating difficulties in the supply of various materials used in everyday medical practice, and some of these, also, are urgently needed in the armament industry. Glycerin is an obvious example, and, in combination with iodine, was recently advocated in these columns for the treatment of wounds sustained in air raids. If there are other applications equally efficacious—as indeed there are—they should be used in preference to any that contains glycerin. Another substance we would urge practitioners to use sparingly is alcohol, whether in the form of surgical spirit or of medicinal tinctures. The use of surgical spirit is a familiar ritual, but it may be recalled that Colebrook showed that dettol applied to the skin is remarkably effective in killing surface bacteria. In the whole field of surgical antisepsis the practitioner should ask himself what other antiseptic would do just as well as spirit and use it. We hope to publish a further statement on this subject.

THE TAVISTOCK CLINIC

The Tavistock Clinic (the Institute of Medical Psychology) has just issued its report for 1940, the twentieth year of its existence. All concerned with the clinic are entitled to congratulations, for the report shows that, in spite of the untoward circumstances and the consequential loss of staff, both medical and lay, and change of location, the clinic has been able to maintain uninterruptedly its useful activities. It has left Malet Place and is now housed at Westfield College, Kidderpore Avenue, Hampstead, N.W.3. It has not been possible to re-establish its small in-patient department, but the spirit and tradition of the institution have been preserved and sustained. It was not until the last quarter of the year that there was a significant and serious fall in the number of patients. This is ascribed to the intensified air raids on London and the large evacuation of children and exodus of considerable numbers of the popuation. The report, however, says that "during the last few days of the year there was a marked increase in the number of applications for treatment. This may be attributed to improved adaptation on the part of patients to the difficulties and risks of travel rather than to an increased incidence of neurosis. We can confirm the fact that bombing has so far produced few cases of breakdown among civilians." In its earlier years the clinic suffered from a certain scepticism and aloofness on the part of the generality of practitioners in regard to a relatively new field of medicine, and from the factions in psychological medicine which were then well marked. The clinic never associated itself with any of these factions and has steadily pursued its middle course, developing increasingly by intimate relationships with general medicine, and aiming, both in its teaching and research, at linking the concepts of psychopathology with the findings of the physiological laboratory and clinical practice. This report should quicken interest in the work of the clinic and encourage the support of the medical profession and of educationists and sociologists.

We announce with great regret the death at the age of 85 of Sir D'ARCY POWER, K.B.E., F.R.C.S., eminent alike for his work as a surgeon and as a medical historian, biographer, and bibliographer. Sir D'Arcy was a faithful friend to the *British Medical Journal* and its Editors, wrote many reviews and many articles and notes in the section "Nova et Vetera," and contributed the opening paper, on some memories of the *Journal* and the profession, for the Centennial Number published on October 5, 1940.

On Thursday, June 5, at 5.30 p.m., Mr. John G. Winant, the American Ambassador, will attend the Lloyd Roberts Lecture at the house of the Royal Society of Medicine in order that he may receive the Hickman Medal, awarded by the Society, on the recommendation of the Section of Anaesthetics, to Dr. A. E. Guedal of Los Angeles. Immediately after the ceremony of presentation, the Lloyd Roberts Lecture will be delivered by Prof. Julian Huxley on "Art as a Social Function." Admission of Fellows and their friends will be by ticket only. Early application should be made to the Secretary at 1, Wimpole Street, W.1.

TREATMENT OF AIR-RAID CASUALTIES

BY

S. JOSEPH HOFFMAN, M.B., F.R.C.S.Ed.

It is not proposed to advance an excuse for adding to the literature that has accumulated on the treatment of air-raid casualties. The subject is one of importance, and some benefit may accrue from the consideration of a routine technique that was gradually evolved during a year's experience of numerous raids while R.S.O. at a hospital in the south of England and later consolidated elsewhere. The total number of casualties thus far treated exceeds 700.

Method of Reception of Casualties

Early raids were fortunately on a small scale, casualties rarely exceeding fifty. Yet even these comparatively small numbers placed a severe strain on the elaborate schemes that had been evolved for the reception of patients. In theory the concept of resuscitation wards, recovery wards, hysteria wards, "awaiting *x*-ray" wards, etc., was most attractive; in actual practice it proved a complete failure. The same applied to the marking of patients with different colours to signify type and degree of injury, and urgency or otherwise of treatment. In the heat of the moment one never seemed able to remember what colour stood for what.

All previous schemes were therefore scrapped, and the existing facilities for dealing with "ordinary" accidents were merely amplified. All cases were admitted through the accident room in the usual manner. Here a rapid but comprehensive examination was made, and the findings were jotted down on a card, which was pinned to the patient's clothing. There was no attempt to decide whether operative intervention was urgently required or not, as this was deemed to lie within the province of the operating surgeon.

A careful search was made for the presence of a tourniquet, and if this was found it was removed forthwith. Usually little or no bleeding follows even when limbs have been blown off. This is because the elastic coat of the artery retracts and plugs the vessel, and the veins twist up on themselves. In the rare case in which haemorrhage was still brisk—as when a vessel had been half divided and so could not retract—an attempt was made to control it with artery forceps. If this succeeded the tourniquet was left off; otherwise it was reapplied. Finally a firm bandage over wool was applied, and this almost always controlled all bleeding. A.T.S. 2,000 units was administered as a routine, together with morphine, and the patient was then transferred to the ward. The time-honoured dosage of morphine grain 1/4 is almost without effect; a minimum of 1/2 grain and often 1 grain is required. In particularly restless and psychically shocked patients this is best given intravenously. The injection must be made very slowly, and 1/2 grain is the maximum that can be safely given in this way. The effect is almost instantaneous.

Pre-operative Treatment

Every casualty is suffering from shock and requires adequate anti-shock treatment before operation. This fact now seems axiomatic. But in the first flush of enthusiasm one tended to overlook it and to rush cases into the theatre prematurely. This was particularly so with wounds of the thorax or abdomen. It resulted in successful operations but, unfortunately, in dead patients. In fact, after the first raid our mortality rate was over 40%, in spite of every operation having been completed within six hours of the raid.

On reaching the ward the patient is transferred to bed between warmed blankets, and anti-shock treatment is started. No attempt is made to undress the patient, the clothing being merely loosened where tight. If it is necessary to expose any area the overlying clothing is cut away. Every effort is made to disturb the patient as little as possible. As a preliminary measure the blood pressure is taken. It is invaluable both as a prognostic measure and as an index of response to treatment and fitness for operation. A systolic pressure below 80 almost always means that anti-shock treatment will fail and that death will ensue.

Measures against Shock

The anti-shock measures are best described in the following categories:

1. *Rest (both Mental and Physical).*—This is attained with the morphine. If the dosage so far given is ineffective the drug is repeated forthwith, preferably intravenously in order to get an immediate effect. At the same time temporary splints are adjusted so as to ensure immobilization of injured limbs.

2. *Heat.*—This is best attained with a radiant-heat cradle. Cradles were made in bulk by the hospital electrician at a cost of some 30s. each.

3. *Fluid Replacement by Venoclysis.*—The solution of choice is plasma. It is put up in vacoliters, and the assembly of the apparatus and introduction of the needle into a vein take but a few seconds. In a moderately severe case at least four pints is required. This is to be regarded as a basic minimum and may be insufficient. It is given as a fast drip at room temperature. It must be stressed that it is useless to pour in plasma at one end if it is leaking out almost as fast at the seat of injury. Literally pints can be lost through a lacerated wound of moderate severity within a few hours. Therefore a vigilant eye is kept on dressings, and if these become moist they are immediately taken off and the wound inspected. If necessary a tourniquet is tightly applied just above the site of injury, and this effectively prevents any further plasma leak. Naturally the tourniquet is loosened at twenty-minute intervals.

4. *Oxygen Therapy.*—This is an important adjuvant in the treatment, and quite dramatic improvement may follow the correction of tissue anoxaemia. The oxygen is best given through the B.L.B. mask. This latter is practically foolproof and, once adjusted, requires a minimum of attention. The technique of application, too, is simple. But one tip to the tyro: Use either a flowmeter or else a full oxygen cylinder.

Operative Treatment

This is undertaken as soon as the maximum response is thought to have been obtained from the anti-shock therapy. It is essentially a question of surgical judgment; but in the borderline case the blood pressure gives invaluable aid. To operate while the systolic pressure is still under 100 is to court disaster. It must be borne in mind, however, that with fractures of the long bones complete recovery from the shock is not obtained until the displacement has been rectified. If thought necessary the venoclysis is continued throughout the operation.

The choice of anaesthetic is important. My preference is for sodium pentothal. I would remind those who use it, however, that the specific antidote is picrotoxin, and would suggest that ampoules of the latter kept on the anaesthetic table may prove life-saving.

Technique

This naturally varies with the site and extent of the injury. However, in all cases certain principles are observed:

(a) No more is done than is essential to save life. After all, that is the prime function of the traumatic surgeon. Therefore one errs on the side of conservatism, deferring all procedures not essential to this end until a later date. (b) Primary suture of anything except clean incised wounds is

never done. (c) Amputation is rarely performed as a primary procedure unless the blood supply is irretrievably lost.

The usual type of injury commonly involves the limbs, and it is proposed to describe the method used in dealing with such a lesion:

1. The wound is exposed, and the surrounding healthy skin (from the joint above to the joint below) is scrubbed with soap-and-water and then painted with iodine.

2. The wound itself is scrubbed with a brush and dilute lysol water—2 drachms to the pint. This stains all dead tissue a dirty greyish white, and makes its subsequent recognition easy.

3. The wound is flooded with hydrogen peroxide, and this in turn is washed out with spirit or ether.

4. All dead tissue is now excised, beginning with the skin and working inward. A minimum of skin edge is removed. An effort is made to remove all foreign bodies; and the generally expressed view, that most metallic foreign bodies can be safely left, is not agreed with. They are a potent source of chronic wound sepsis, and may be one of the predisposing factors in the development of gas gangrene. Efficiency in locating and removing pieces of shrapnel comes only with experience. The wound is excised down to the deep fascia, and the point of penetration here is easily recognized. This is excised, and a finger is now gently insinuated into the track, and the latter is followed down as far as the finger will go. If the shrapnel is still not reached, a second incision is made on to the finger-tip; the finger is withdrawn from the track, reinserted through the new opening, and the track again followed up. This procedure is repeated, if necessary, until eventually the shrapnel is felt, when it is removed with a pair of forceps. It is necessary to stress the need for the utmost gentleness. "False passages" in the muscles are humiliatingly easy to make, and once one gets outside the original track it is well-nigh impossible to get back. By this means it is possible to trace a missile all the way up from the knee to the thigh with the minimum of tissue disturbance. In point of fact I have vivid memories of watching my ex-chief (who was an Army surgeon in the war of 1914-18) doing so, and producing a piece of metal the size of a golf ball from beneath the upper end of the adductor magnus—the entrance wound being in the region of the knee. No mention has been made of radiological localization. It was not found practicable to radiograph more than some 5% of cases. The time factor, and also sheer weight of numbers, precluded the use of this aid except where considered essential.

5. Toilet having been completed, the wound has a guttered appearance, being almost as wide in its depths as on the surface. Large bleeding-points are tied off, but all others are left, the aim being to reduce to an absolute minimum the foreign material (in this case catgut) in the wound.

6. Finally, the wound is well smeared with "zisp" and then packed with gauze impregnated with the same material. The bone ends, if severed, are manipulated into position, and the limb is immobilized in plaster-of-Paris. Primary suture of the wound is virtually never performed.

"Zisp" calls for some explanation. Its formula is:

Zinc peroxide
Iodoform
Sulphanilamide powder } equal parts
Paraffin, q.s. to make a thin paste.

The mechanical action is similar to that of the petroleum-jelly gauze in the Winnett Orr treatment, but there would appear to be several decided advantages. The emulsion is a deodorant. Thus there is none of the fetid odour which emanates from the patient subject to the Winnett Orr method, and it is possible to retain the plaster for as long as desired. The zinc peroxide liberates oxygen, and so retards the growth of anaerobic organisms. The inclusion of the sulphanilamide needs no comment. In spite of foreign views to the contrary, most surgeons agree that it plays a large part in keeping wounds aseptic.

Post-operative Treatment

This is virtually the same as originally recommended by Winnett Orr, except that it is not necessary to change the plaster because of the smell. One is guided by the general condition, by the pulse and the temperature, and by the local condition as evidenced by pain. Usually the temperature and pulse are normal, and the patient is comfortable within two days. Persistent pain and a rapid pulse are each an indication *par excellence* for removal of the plaster and inspection of the wound.

A final word about the late management of the wound. Frequently it does very well for a time, and then inexplicably hangs fire. It is at this stage that small doses of insulin may work miracles. Five units night and morning suffices.

Question of Gas Gangrene

I have had the misfortune to see eleven cases of gas gangrene since the war began. Clinically these can best be divided into two groups, although in all cases the causative organisms were discovered.

Mild Cases

These usually occur in wounds which have been subjected to inadequate toilet and to primary suture. The patient is moderately toxic, with a temperature around 102° and a pulse rate around 120. The suture line is obviously under tension, and the wound is resonant to percussion. On removal of the sutures a thin dirty brown fluid, teeming with anaerobic Clostridia, seeps out. In this type a 100% cure can be expected from a combination of relief of tension, deep therapy, and chemotherapy. Ablation is never required.

Severe Cases

Here the clinical picture is a different one. The patient is acutely ill and highly toxic. The temperature is not high, but the pulse is rapid and thready. The mental state is a characteristic one, the patient being hyperalert, and probably asserting that he had never felt better. Locally the limb has a tense drum-like appearance and characteristic odour. The skin has a mottled marbled appearance with typical venous marking. The arteries are not palpable. This is a true gangrene and the blood supply is occluded, though whether this latter be cause or effect is problematical. It spreads almost as one watches it, and surgery should be considered both urgent and imperative. Local intervention is meddlesome, and in immediate ablation lies the only hope.

At operation the limb is removed by a transverse incision, but the bone is divided as high above the skin level as possible. No attempt is made to get above the upper limit of infection, if necessary one being quite satisfied to go through the typical greyish mushy muscle. Haemorrhage is scanty, and only the main vessels are tied off. The wound is then packed with acriflavine in paraffin gauze, and the pack is held in position by three or four skin sutures

Post-operative treatment consists in a combination of intensive chemotherapy with sulphapyridine, deep therapy, venoclysis of glucose in saline, and anti-gas-gangrene serum. Three of the four cases of this type that I was associated with recovered on this regime. Four days later the skin sutures are divided and the pack removed. The wound now presents an amazing appearance. It literally looks as if it has just been made. This is because the acriflavine retards the formation of granulation tissue. Under local anaesthesia secondary suture is performed just as though it were a fresh wound, and healing virtually occurs by first intention. This method of performing the amputation is as fast as the true guillotine operation and has none of its disadvantages.

My thanks are due to Mr. H. John Nightingale, senior surgeon to the Royal South Hants Hospital, who is responsible both for my interest in traumatic surgery and for teaching me its principles and practice.

The annual general meeting of the Royal Medical Benevolent Fund was held at the house of the Royal Society of Medicine on May 14, when Sir Thomas Barlow, Bt., was re-elected President, Dr. Lewis G. Glover Honorary Treasurer, and Mr. R. M. Handfield-Jones Honorary Secretary. The accounts for the year ended December 31, 1940, were presented and adopted for circulation to subscribers.

LIVER RATIONS: SENSITIVITY TO MARGARINE

The following two statements, one on Rations of Fresh Liver for Cases of Pernicious Anaemia, and the other on Sensitivity to Margarine, have been received for publication from the Medical Research Council.

FRESH LIVER FOR PERNICIOUS ANAEMIA

Owing to the present shortage of supplies of raw liver the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council were asked by the Ministry of Food to advise as to the necessity for providing special rations of fresh liver for the treatment of pernicious anaemia. The committee advised that fresh liver was not necessary for the treatment of cases of pernicious anaemia, save for those rare patients in whom it was proved that parenteral injection of liver extract caused anaphylactic shock. The Ministry of Food have accordingly made no provision for allowing extra rations of fresh liver to cases of pernicious anaemia in general, but have arranged that, on the production of a medical certificate giving adequate proof that liver extracts administered parenterally give rise to anaphylactic shock, such rations may be available for particular patients. Applications for rations of raw liver on this special ground should be supported by full medical evidence and should be sent to Prof. J. C. Drummond, Ministry of Food, Neville House, Page Street, London, S.W.1, for submission to the Ministry's medical advisers. The advice of the committee was based on the following considerations: treatment of pernicious anaemia by means of parenteral injection of suitable liver extracts is, in practice, more efficient than treatment by ingestion of raw or lightly cooked liver; treatment by injecting liver extracts is the cheapest way of treating pernicious anaemia; the continued supply of fresh liver cannot be guaranteed under present circumstances, while liver extracts, by reason of their keeping properties, are likely to continue available.

Resistance to Injection of Liver Extract

It is now well recognized that the treatment of a case of pernicious anaemia cannot be considered satisfactory unless it succeeds in maintaining the red blood cell count at a figure of 5,000,000 or more per c.mm. and the haemoglobin concentration at a figure of 100% (Haldane) or more. If these figures are allowed to remain at lower values, then the patient, although perhaps feeling in good health, is exposed to the danger of developing subacute combined degeneration of the cord. While it is perfectly possible to raise and to maintain the red blood corpuscles and the haemoglobin percentage at these necessary values by the ingestion of fresh liver the amounts that it is required to ingest to do so are such that few patients continue to take them, as they should, indefinitely. With suitable liver extracts, on the other hand, the necessary criteria of successful treatment may be maintained, once the necessary levels have been attained, by the intramuscular injection of 1 c.cm. or 2 c.cm. of a suitable liver extract at intervals which are seldom less than two weeks. Despite the manifest advantages of the treatment by injections, however, objection has been raised to it on the ground that certain patients, while reacting satisfactorily to treatment by ingestion of liver, are resistant to treatment by injection of liver extracts. Assuming that the diagnosis of pernicious anaemia is correct, there are two reasons why such an impression may be gained. First, there are available on the market at present certain highly concentrated liver extracts which may not be efficacious in certain cases of pernicious anaemia which react well to ingestion of fresh liver. In such cases, however, it has been found that a satisfactory result is obtained when less concentrated, and incidentally cheaper, liver extracts are used. Second, it is not infrequently found that the initial expected improvement with treatment of a previously untreated case of pernicious anaemia is delayed, and this is especially so in cases complicated by sepsis or an infection or with arteriosclerosis. If in such cases treatment is commenced by injection of liver extracts and then, when the expected improvement does not speedily appear, the treatment is changed to ingestion of fresh liver with apparent speedy improvement the impression may thereby be gained that the patient is resistant to treatment by parenteral injection of liver extract. Actually this apparent resistance would, in such a case, be simply a manifestation of a delayed reaction to treatment, and if the treatments had been given in the reverse order the opposite impression would have been obtained. So convinced are the members of the Food Rationing (Special Diets) Advisory Committee that these are the usual explanations of the alleged resistance of true cases of pernicious anaemia to parenteral injection of liver extracts that they have agreed to test any case of pernicious anaemia in which the medical practitioner is convinced that such is not the explanation of why a particular patient reacts to ingestion of fresh liver while proving resistant to injection of liver extracts. Application for such a test to be made, accompanied by full medical data, should be sent to Prof. J. C. Drummond, Ministry of Food, Neville House, Page Street, S.W.1.

The above considerations apply to true cases of pernicious anaemia. A blood picture similar to that of pernicious anaemia may occasionally occur in other conditions and liver may have no effect in these cases. These cases are of two main types: cases with extensive disease of the bone marrow usually of malignant origin; cases in which by reason of advanced disease of the alimentary tract, such as sprue, short circuits, etc., there is marked failure of intestinal absorption and signs of deficiency diseases are present. For the former cases little can be done; for the latter, successful treatment of the underlying intestinal condition and of any deficiency diseases present may result in the patient becoming responsive to liver therapy.

Economic Considerations

It will be noted that the committee do not advise that patients should use either the liquid or powder preparations of liver designed for oral administration. Their reason for not doing so is that these preparations though undoubtedly efficacious, are uneconomical of the supply of raw liver available. It has been estimated that about fifty times as much raw liver is required for the manufacture of a single dose of a particular oral preparation as is required for manufacturing an equivalent dose of a preparation for parenteral injection. Under the present circumstances the use of oral preparations is, therefore, to be deprecated. The same objection does not apply to the use of oral preparations made from the stomach.

The erroneous impression that treatment by ingestion of fresh liver is cheaper than treatment by injection of liver extract should be corrected by comparing the daily cost to the treated patient of the amount of raw liver it is necessary for him to ingest to maintain his haemoglobin and red blood cell concentrations at the required value with the daily cost to him of an injection of liver extract, costing about one shilling, at intervals of one week or more. It will be seen that the cheapest way of treating a case of pernicious anaemia is by means of injections of suitable extracts of liver.

SENSITIVITY TO MARGARINE

Reduction in the amount of butter available has necessitated rationing regulations by which a varying proportion of the fat ration is made up of margarine. The result is that many persons, who in peacetime never ate margarine now find that this substance is their main source of fat. Since the inception of butter rationing the Ministry of Food have received many requests for special rations of butter from persons who allege that they are unable to take margarine because it provokes in them untoward symptoms. The Ministry of Food have therefore requested the Food Rationing (Special Diets) Advisory Committee of the Medical Research Council to advise them on how to deal with such applications. The committee have carefully considered the evidence regarding sensitivity to margarine, and they have come to the conclusion that, if true sensitivity to margarine exists, it must be a very rare condition.

True and Apparent Sensitivity

In reaching this conclusion the committee were careful to distinguish between true and apparent sensitivity to a food. In true sensitivity the untoward symptoms are provoked whenever the food is taken, even though the quantity ingested is small and even when the offending food is so disguised by its method of preparation that the patient is unaware that she is partaking of it. Apparent sensitivity, on the other hand, is distinguished by the fact that the particular symptoms are provoked only when the patient believes that she is partaking of the particular food; they do not appear when the patient is unaware that she is consuming the article to which she is alleged to be sensitive, although they may appear when the patient, partaking of some other food, receives the impression

that she is actually consuming the offending article. Thus a patient with apparent sensitivity to margarine may retch and vomit after knowingly eating margarine, while she may consume without any untoward effect pastries containing a considerable proportion of margarine. A case of true sensitivity to margarine, if it exists, would be as sensitive to food prepared with margarine as to pure margarine. In this connexion the committee were made acquainted with the results of tests in which persons who were convinced of their ability to detect margarine were invited to partake of a large series of preparations, some consisting of or containing margarine, some consisting of or containing butter. The failure of candidates to distinguish accurately preparations of margarine from preparations of butter demonstrated that the alleged unpleasant properties of margarine, which these persons claimed to distinguish, existed only in the candidates' imagination and were dependent not on any property of margarine itself but on the candidates' prejudices with regard to this substance That the large majority, if not all, of the cases of alleged sensitivity to margarine now applying for special rations of butter are of a similar nature is suggested by a comparison of present experience with that of peacetime practice.

If true sensitivity to margarine actually exists to the extent that the application for special butter rations suggests, then it should be a condition with which all physicians are well acquainted and one which, because of the large consumption of margarine in peacetime, they should have met frequently before the introduction of the present rationing regulations. The lack of experience by physicians in peacetime of unequivocal cases of true sensitivity to margarine suggests that this condition is at least a clinical rarity, and, further, that the majority, if not all, of the persons now applying to the Ministry of Food for special butter rations on the grounds of sensitivity to margarine are in fact not cases of true sensitivity, but merely persons who have previously convinced themselves, erroneously but often quite sincerely, that they cannot take margarine. Nevertheless, medical knowledge on the question of sensitivity to margarine is not sufficiently complete for it to be stated dogmatically that cases of true sensitivity to margarine do not exist.

While therefore the committee are of the opinion that sensitivity to margarine in the vast majority, if not all, of the persons now applying for special butter rations is more apparent than real, they are not prepared to exclude the possibility that in some instances true sensitivity to margarine may exist. The committee have therefore arranged to test the sensitivity to margarine of any person in whom the medical data suggest the possibility of true sensitivity. Applications for the test, accompanied by full medical data, should be sent to Prof. J. C. Drummond, Ministry of Food, Neville House, Page Street, S.W.1, for submission to the Ministry's medical advisers, who, if the medical data warrant it, will undertake to test the patient.

EMERGENCY AMPUTATIONS

M.R.C. WAR MEMORANDUM

The War Wounds Committee of the Medical Research Council has issued M.R.C. War Memorandum No. 5 on "Emergency Amputations" (H.M. Stationery Office, 2d. net). It has been prepared by the Subcommittee on Amputations, consisting of Mr. H. A. T. Fairbank, Surgeon Rear-Admiral G. Gordon-Taylor, Colonel C. Max Page, Mr. P. Jenner Verrall, and Mr. R. Watson-Jones. The following is a summary of the principal points.

The memorandum begins by pointing out that in the treatment of wounds and combined fractures amputation is seldom needed except where injuries are grave and multiple or the main blood vessels of a limb are destroyed. In multiple injury due regard must be paid to the effects of concomitant lesions in deciding whether a damaged limb may be preserved. Where the injury is confined to one limb the main indication for amputation is irreparable interference with the blood supply. A surgeon who amputates because of the severity of the local injury assumes a grave responsibility, and a second expert opinion should always be sought.

Immediate Amputation

The type of amputation suited to a particular case depends upon the time which has elapsed since injury, the level at which amputation is indicated, and the general condition of the patient. It is occasionally necessary to amputate without delay, as in the case of a person pinned down by a weight of masonry; but whenever conditions permit, amputation should be deferred for an hour or two while wound shock is treated. Occasionally, where gross injury to a limb is associated with fracture, an immediate amputation at the level of the wound is the procedure of choice. In some cases it may merely be necessary to sever a few remaining strands of soft parts and excise portions of badly lacerated muscle. Where the local destruction has been less severe the operation will amount to a guillotine operation at the site of injury, save that no further bone section is made. This will conserve maximum bone, but is likely to entail a secondary formal amputation later.

Ordinarily the first six or eight hours after injury may be regarded as a safe period, with a reasonable prospect of first-intention healing of an amputation stump. Principles of treatment comprise excision of devitalized contaminated tissues and primary skin suture. A formal flap operation is performed at the site of election* and the skin flaps sutured in the usual manner. If the time-lag is somewhat greater than six or eight hours, and the wound is near the site of election, or if early evacuation of the patient seems probable, a flap amputation with delayed primary skin suture should be performed. Mattress sutures are inserted in the margins of the flaps, but not tied, and protected from coming out by strips of rubber tubing or buttons, so that light traction may be applied. The traction is discontinued after from two to ten days, if there is no active infection, and the sutures are then tied.

Late Amputation

Indications for late amputation are gangrene due to vascular thrombosis, massive gas gangrene, and danger to life from spreading infection or severe secondary haemorrhage. If more than twenty-four hours have elapsed since injury, flap amputation with primary skin suture is unsafe and may be dangerous. The following are the alternatives:

(1) When primary amputation can be performed well below the site of election—

(*a*) A guillotine or circular flapless amputation at a low level;

(*b*) Flap amputation with the flaps left open or only loosely approximated to cover the raw area. (After each of these forms of primary amputation, a formal flap amputation at the site of election may be carried out when infection and oedema have subsided.)

(2) When the amputation must be at or close above the site of election—

(*a*) If there is viable skin below the amputation level, flap amputation with traction and secondary suture of the skin flaps;

(*b*) If no viable skin below that level, guillotine amputation with continued skin traction until the wound is healed, no other amputation being performed.

In a circular amputation the skin is divided at one level, the muscles at a higher level, and the bone at a still higher. A guillotine amputation is strictly one in which skin, muscles, and bone are divided in the same plane, although the experienced surgeon usually retracts each layer slightly before dividing the next. The purposes of such amputation are to save life in severe infections by removing a limb rapidly, leaving the smallest possible and most easily drained wound and enabling a clean amputation to be done later at the site of election, and to conserve length of stump when skin has been extensively destroyed.

Complications of Guillotine Amputation

Certain precautions are necessary to avoid serious sequelae of guillotine amputation. At whatever level the original

* The site of election for the various amputations is as follows (the minima are given in brackets): Leg, 5½ in. below knee-joint (3 in.). Thigh, 10 in. below top of trochanter (6 in.). Forearm, 7 in. below tip of olecranon (4 in.). Upper arm, 8 in. below acromion (5 in.).

guillotine has been performed, any reamputation must involve division of bone at a higher level. If the guillotine was performed well below the site of election, this is not a disadvantage, but if at or above the site, reamputation at a higher level gives a stump unduly short and possibly useless. If no skin traction is applied, skin and muscle retract, producing a conical stump, with projecting bare bone, and the whole cone must be removed at reamputation, so that the final stump may be far too short. The complication may be avoided by applying skin traction within twenty-four to forty-eight hours of the first amputation. Four strips of adhesive strapping are applied to the skin, the adhesive reaching as near the margin of the wound as possible, and secured by encircling turns of strapping. To each of the strips is attached a cord, leading to a weight suspended over a pulley at the foot of the bed or, if the patient must be evacuated, a Thomas splint may be used, to the lower end of which the four cords are fastened, the ring being pressed up against the tuber ischii. Detailed drawings of these applications are included in the memorandum.

If the raw granulating surface is repeatedly dressed the patient suffers severe pain, with fluid loss and danger of secondary haemorrhage. This can be avoided by using the "infrequent dressings technique" (as in the Winnett Orr and Trueta treatment of infected wounds). To minimize the risk of secondary haemorrhage in high guillotine amputation of the thigh, it is advisable to ligate the femoral artery in its continuity just below Poupart's ligament at the time of the amputation. If reamputation be performed too soon, healing will not be by first intention, and a second amputation may be necessary, with further shortening of the stump. This can be avoided by deferring reamputation not only until the granulating surface is clean, but until all oedema has disappeared.

Indications for guillotine are as follows: (1) cases reaching the surgeon in such a desperate condition that only an operation performed with this speed and simplicity holds out promise of recovery; (2) cases of persons caught by a limb in machinery or held down by masonry; (3) cases of severe infection or gangrene where the section of the limb can be placed at a low enough level to permit subsequent reamputation at the site of election; (4) cases needing amputation at the site of election or close above it where no skin is available below that level and it is proposed that the guillotine shall be the final amputation.

A flap amputation cannot be performed quite as quickly as a guillotine, and the area of exposed tissue is greater; but there are circumstances in which this operation is preferable. If the site of amputation is determined by the destruction and infection of muscles, the skin below this level being viable, and if the level is at or above the site of election, generous skin flaps should always be cut, the muscle and bone divided at the higher level, and mattress sutures inserted in the skin flaps for continuous traction.

GLASS SUBSTITUTES AND PROTECTION FROM FLYING GLASS

The vast number of casualties, most of them minor but some major, caused by broken glass, prompted an exhibition of the materials now available as substitutes for window glass and the means of protection from glass splinters. This was housed at the Building Centre, New Bond Street, London, and was designed to illustrate the methods of carrying out the recommendations of the Ministry of Home Security as embodied in a memorandum published by its Research and Experiments Branch. A wide range of materials was on view, the larger number of them being some form of textile netting or of cellulose film. The substitutes for glass vary in price from 1s. 6d. to 10s. a square yard; they are weatherproof and capable of being fixed to the metal frames of windows with a special composition. They include netting impregnated with a gelatin-like material, cotton backed with a rubber solution, a kind of bakelite which has the appearance of corrugated iron, wire buried in cellophane, and a material called "dufayglass," which is a cellulose acetate film reinforced with cotton net. To prevent glass from scattering there are various kinds of net to be affixed to glass by wetting and pressure, blinds of black cloth with rubber backing, and wired glass and glass bricks which have been found to withstand severe fire tests and even to retard fire. These bricks form an architectural feature, give a considerable diffusion of light, and, illuminated, might be used to indicate the position of shelters. One of the complications of window protection is that the blast wave has a kind of "S" form, and may cause the glass of the window to fall either outwards or inwards, according to the phase which is in operation at a particular spot. To ensure more complete protection panes should be treated on both sides, which means a further heavy diminution in transparency. The exhibition also showed how the science of ventilation is adapting itself to black-out conditions. Intake ventilators were shown which can be fixed to glass, wood, or metal. One special contrivance fixed to a window frame permits the window to be partially open during black-out. There are ingenious vents in the pelmet and cowls arranged in such a way as to provide the maximum of ventilation while observing the lighting regulations. If the ideas find wide adoption the third war winter should see the problem of interior stuffiness solved.

Local News

ENGLAND AND WALES

London School of Hygiene and Tropical Medicine

A report on the work of the London School of Hygiene and Tropical Medicine, which incorporates the Ross Institute, has been made for the year 1939-40. Since the end of the period covered by the report Sir Wilson Jameson has resigned his post as dean on his appointment as Chief Medical Officer of the Ministry of Health, and Lieut.-Colonel G. S. Parkinson has been appointed dean for the duration of the war. The war has seriously affected the work of the school, but programmes of research have been carried out as well as a limited amount of teaching, and short intensive courses have been given for persons about to undertake service in the Tropics. The department of clinical tropical medicine suffered a serious blow when the Hospital for Tropical Diseases was closed on the outbreak of war, but as a temporary measure ten beds were allocated at the Dreadnought Hospital, Greenwich, for cases of the type which previously had been admitted to Gordon Street. The Dreadnought itself has since been damaged, so that other provision for the teaching of clinical medicine has had to be made. The department of parasitology has been transferred to St. Albans, where an investigation on subclinical helminthiasis in Great Britain has been continued, as well as other studies. Investigations on lice have occupied the department of entomology, and the use of modern insecticides in controlling lice has been carefully examined. In the department of epidemiology and vital statistics a great deal of statistical work relating to air-raid casualties has been undertaken. In the public health department the behaviour of the skin, especially in relation to the effects of clothing, has been one of the subjects of study, and workers in this department have also assisted in the Medical Research Council's extensive investigation of pulmonary disease among anthracite miners in South Wales. A certain amount of teaching has been given in the department of medical industrial psychology, especially for medical men taking up work in industry, and for industrial nurses. The Ross Institute has also maintained its activities very well throughout the year in spite of great difficulties. In the earlier part of the year the director of the Institute, Sir Malcolm Watson, visited India and West Africa, and, among other matters, made an extensive study of malarial control work. A list is given in the report of nearly one hundred papers which members of the staff of the school and of the Ross Institute have contributed to scientific journals. The accounts show a substantial surplus on the year's working, thanks largely to the generous aid of industrial concerns with interests in tropical countries.

Liverpool Psychiatric Clinic

That the war has made little difference to the activities of the Liverpool Psychiatric Clinic is revealed in the report presented to the recent annual meeting. The clinic has now, however, no paid medical personnel, and were it not for the devoted services of its five honorary physicians it would have to close down. The report states that "psychologically speak-

ing, enemy action upon Merseyside has had little direct result." A few cases have been dealt with of civil defence and armament workers subjected to prolonged and excessive stress, but it had been anticipated that concentrated aerial bombardment or even the threat of air raids might cause numerous cases of alarm, distress, or even panic. An intensive course of instruction has been given to selected volunteers to fit them as auxiliary mental health workers in such circumstances, and eighteen workers were prepared in Liverpool and warned for service, but so far—the report takes the story to the end of 1940—none of them has been required in that capacity. The new patients attending the clinic in 1940 numbered 261 and the attendances 1,710. At the same meeting Mr. D. W. Harding, senior lecturer on psychology at the University, gave an address on mental health in post-war reconstruction.

Correspondence

Obscure Nervous Effects of Air Raids

SIR,—I read with interest and can endorse Mr. Tom Harrisson's excellent clinical observations (April 12, p. 573). These are, however, not limited to air-raid casualties, as similar cases occur as sequelae to a variety of conditions, notably influenza; from a medical point of view their symptoms are mental and not neurological. Dr. Clifford Allen (May 10, p. 727) also emphasizes the frequent occurrence of mild cases of stupor, and his "reflex reaction" is reminiscent of the behaviour of patients who endure a minor operation, then collapse a minute or so *after* the last bandage is in position.

My experience of the pathology of air-raid casualties is so far very limited; ideal material for histological examination is of course unobtainable, since death itself is a more advanced state than concussion. I have, however, come to the conclusion that the pathology of both immediate and remote effects is essentially vascular. One of my air-raid casualties had gross vascular lesions in the brain stem and at the large nerve roots (optic chiasma)—obviously due to severe tissue stretching along the spinal axis. Another casualty did not show such localization, but had a fractured lumbar spine. The brains from these cases and from some intracranial pressure experiments on animals all showed defective staining with the benzidine technique. This defect I attribute to a tissue acidity from anoxia, which arises when the vascular network is deformed, since the stretching acts as a mechanical irritant in causing capillary constriction. Neurone function is not affected by this stretch. I have recently shown that conduction in the frog's nerve is unimpaired by severe stretching even up to the moment of rupture of its muscle attachments.

When the tissues about the posterior hypothalamus are stretched (with resulting capillary constriction) unconsciousness results (Bailey); and it is logical to conclude that if the return of consciousness is delayed, partial, or associated with mental changes, many such constricted capillaries have failed to reopen properly. An effective blast wave has a pressure of from twice to a hundred times that of normal blood pressure, so that not only deformations of tissue with stretching and capillary constriction occur but also undue and partially irrecoverable distension of larger cerebral vessels are histologically demonstrable (for example, rupture of the elastic or muscle coat of the arteries; rupture, dilatation, and stasis in the veins).

Depending upon the extent and locality of these combined lesions and their vascular sequelae, labile sensori-motor associations are disturbed, resulting in abnormal behaviour which sometimes resembles that of post-lethargic encephalitis as noted by Dr. H. Crichton-Miller (April 26, p. 647). I have no doubt that such pathology would be enhanced and maintained by chronic nasal sinusitis in a manner similar to that by which such toxi-infective conditions produce cerebral vascular lesions in mental disorder cases.—I am, etc.,

Birmingham, May 15. F. A. PICKWORTH.

SIR,—In his letter (May 10, p. 727) Dr. Clifford Allen has suggested that concussion can be caused by blast, and that damage to the cribriform plate and nasal sinuses may occur sufficient to allow spread of infection to the meninges. This latter suggestion is very important, but I cannot agree with the former. Investigations on the effects of blast on the central nervous system have been pursued at the same time as the other studies on the effects of blast carried out for the Research and Experiments Department of the Ministry of Home Security under the direction of Professor S. Zuckerman. We have never seen any signs of unconsciousness in any of our surviving animals even within 10 seconds of exposure. A monkey which had suffered lung damage which caused death from pulmonary oedema in two hours was immediately capable of co-ordinated activity. Some of our animals have shown signs of fright and have refused to feed for a few hours after exposure, but their behaviour has been otherwise normal. On the other hand, there is no doubt that a recognizable picture of concussion can be produced in animals by impact.

The results of a specially conducted survey of air-raid casualties have shown that concussion does not occur apart from the impact of the skull with a solid object. A feeling of being "dazed" is common, but this, without retrograde amnesia and without a period of unconsciousness, does not constitute concussion.

Blast, in fact, does not "act like a solid body." Where it encounters an air space in which the pressure cannot change as rapidly as the pressure outside it, the walls of the air space will be distorted and may break. This is equally true of the windows of a room and of the tympanic membrane as a wall of the middle ear. We have suspected that it may also be true of the nasal sinuses and air passages, to which pressure may be transmitted by the relatively inconipressible tissues of the head. Thus damage to the cribriform plate might occur without the impact of a solid body. The existence and importance of this effect are under investigation, and we are indebted to Dr. Clifford Allen for his suggestion of its clinical importance.—I am, etc.,

University Laboratory of Physiology, Oxford, May 13. D. WHITTERIDGE.

Renal Complications of Sulphapyridine

SIR,—We had a similar case in 1940 to those mentioned by Major F. R. Fletcher (February 15, p. 242), Mr. J. C. Leedham-Green (April 19, p. 586), and Dr. J. Rowland Hughes (May 10, p. 730). A man aged 44 developed acute influenzal pneumonia. In three days he received 12 grammes of sulphapyridine, and was much better on the evening of the third day. At 8 a.m. on the fourth day he developed violent pains in both loins, passed two ounces of blood-stained urine, and then had complete anuria. This lasted for twenty-four hours. He was to be admitted to hospital, when we gave him 40 grains of potassium citrate orally. Two hours later he passed 40 ounces of blood-stained urine, and from that time his kidneys functioned quite normally. Unfortunately ten days later he developed an empyema and had to have a rib resection but after a stormy convalescence he made a good recovery. It might be worth while to use potassium citrate orally before trying intravenous medication in such cases.—We are, etc.,

HAMILTON F. MOFFIT, L.R.C.P.&S.I.

Aberdare, May 14.

Tuberculosis in the Army

SIR,—In a communication in the *Journal* of March 22 (p. 441) Major G. D. Kersley, discussing pulmonary tuberculosis in soldiers, makes the following statement: "Cooper (1940) says that 5% of recruits to the 6th Division of the A.I.F. were turned down by medical boards on account of phthisis and that another 0.9% were later discovered by microradiography, of which over half appeared to be active." This suggestion—that of every twenty Australian men of military age one should be suffering from phthisis, diagnosable by medical boards presumably not using mass radiography—appeared to me to be so remarkable that I looked up once more Cooper's excellent paper (*Journal*, August 24, 1940, p. 245), abstracted in the *Bulletin of War Medicine*, January, 1941, p. 179. I could find no confirmation of the figures given by Major Kersley, since Cooper claims that 0.55% of the men were found by microradiography to have active tuberculosis; he does not say how many recruits were found to be tuberculous by the medical boards. The figures given by Major Kersley suggest that far more cases of tuberculosis are detected by clinical examination than by microradiography, whereas precisely the opposite impression is given by Cooper's

VITAMIN THERAPY

THE VITAMIN B COMPLEX

In the early days of vitamin research the complexity of vitamin B was not fully appreciated, but advances in nutritional knowledge have since differentiated the various factors of the B complex and new methods of assay have provided reliable quantitative data.

EFFECT OF VARIOUS FACTORS

Biological experiments with adermin (vitamin B_6) have proved its usefulness in various syndromes. Improvement has been recorded in certain cases of idiopathic epilepsy, in amyotrophic lateral sclerosis, and in hypertrophic muscular dystrophy. Decreased stiffness and rigidity have followed its use in non-postencephalitic parkinsonism.

The particular deficiency symptoms which have responded to vitamin B_6 administration are extreme nervousness, insomnia, irritability, cramping abdominal pain, muscular weakness and rigidity with difficulty in walking.

Clinical grounds for considering the administration of other factors of the B complex may be classified as follows:—

Established or conditioned deficiency of vitamin B_1 (aneurin)

Beri beri.	Lactation.
Alcoholic neuritis.	All restricted diets, especially those for gastric and duodenal ulcers, colitis and diabetes.
Pregnancy, especially with polyneuritic symptoms.	Rheumatoid arthritis (B.M.A. Committee's Rep. Section IX e).
All conditions with a raised metabolic rate, e.g. pyrexias, hyperthyroidism.	Poor appetite, especially in children.
Cardiac decompensation.	

The conjunction of such a large number of apparently unrelated clinical conditions is less surprising when it is remembered that vitamin B_1 is known to be essential for normal carbohydrate oxidation in the tissues. Similar considerations may also apply to other constituents of the B_2 complex such as riboflavin and nicotinic acid.

Established or probable deficiency of riboflavin or nicotinic acid

Roughening of the skin bordering nose and mouth (riboflavin).	Pellagra and other conditions with porphyrinuria (nicotinic acid).

From the point of view of ease of treatment it is indeed fortunate that this wide range of vitamins is found occurring in one substance to the extent shown in the table.

	% of daily requirement supplied by 1 oz. Bemax
VITAMIN B_1 (aneurin)	60
VITAMIN B_2 (riboflavin)	45
P.P. factor (nicotinic acid)	22
VITAMIN B_6 (adermin)	probably 100
VITAMIN E (*a*-tocopherol)	100+
IRON (available)	25
COPPER	25

A distinction must be drawn between the use of Bemax as a dietary supplement and its use as a therapeutic agent. In the former case ½ oz. daily is normally sufficient. In the latter, dosages between 2 and 4 oz. may be used and will furnish, inexpensively, very substantial amounts of the various factors of the B complex. The fact that 1 oz. of Bemax will, in addition, supply 10 grammes of *first-class* protein is of especial importance under war-time conditions.

Clinical sample of Bemax and literature on application to: Vitamins Ltd. (Dept. BN), 23, Upper Mall, London, W.6.

VITAMIN E (*a*-tocopherol)

The use of wheat germ oil in the treatment of cases of sterility and habitual abortion of dietary origin is the result of research extending from 1920 until the present day.

The treatment, according to published reports, has been successful in about 70 per cent. of cases. The classical experiments were all carried out using *whole* wheat germ oil.

Wheat germ oil is now also being increasingly used for cases of primary muscular dystrophy, amyotrophic lateral sclerosis, after poliomyelitis and in rarer cases such as amyotonia congenita.

Indications are that natural sources of vitamin E, such as Fertilol and Bemax, are more effective clinically than synthetic products, possibly because other vitamins present in them may enhance the activity of vitamin E. Whole wheat germ oil has been available since 1934 as Fertilol, which is a highly active *natural and stable* source of vitamin E, plus the other naturally occurring factors of wheat germ oil. Complimentary box on request.

Vitamins Ltd. (Dept. BFE), 23, Upper Mall, London, W.6.

In addition to Bemax and Fertilol dealt with above, Vitamins Ltd. also supply the following pharmaceutical products:

BEFORTISS (Brand) Concentrated Vitamin B	*Tablets.* 200 i.u. and 2 mg. per gm. For high dosage of the B complex. *Ampoules.* 2, 10 and 25 mg. For high vitamin B_1 dosage.
COMPLEVITE Tablets *Vitamin and Mineral supplement.*	To make good the recently estimated deficiencies of vitamins and minerals in the average daily diet.
PREGNAVITE Tablets *Vitamin and Mineral supplement.*	To ensure an *adequate* supply of vitamins and minerals to meet the special requirements of pregnancy.

Physical Medicine, Orthopaedics, and Rehabilitation

SIR,—In an annotation (April 26, p. 633) you claim that the poor results of massage, ultra-violet light, short-wave, and other electrical currents could have been avoided by physical medicine experts, because in such hands these measures "might never have been employed in that way." The meaning of this observation is obscure, but surely it is well known that all such passive treatment failed because it was elevated to a status of false importance, so that patients were deluded into believing that they need only sit back and be cured. Inertia was induced, indolence was promoted, and finally the will to recover was lost. Your suggestion that consultants are needed for "the expert prescription of massage" because otherwise practitioners leave the choice of method to the "trained—but not medically trained—technician," is no more convincing than would be the suggestion that consultants are needed for the expert prevention of bed-sores, in order not to leave treatment to the trained—but not medically trained—nurse. You say that physical medicine consultants are required because "orthopaedic surgeons have inadequate knowledge of the various means employed in physical medicine." About two-thirds of the time of an orthopaedic surgeon is engaged in methods of physical medicine, and we do not know upon what grounds you suggest that his knowledge is inadequate. But assuming that the criticism is justified, is the remedy correct? You may have similar grounds for charging urological surgeons with inadequate knowledge of cystoscopy, and neurologists with inadequate knowledge of spinal puncture. Would you therefore create consultants in cystoscopic apparatus and consultants in lumbar puncture? Finally, and most dangerously, you make the astonishing observation—"Orthopaedic surgeons have been heard to claim that they are capable of seeing their cases through from beginning to end." How short a time since you yourself fought to achieve that very object! In pleading for the organization of orthopaedic and fracture services you insisted that there must be "continuity of treatment" and "unity of control." The British Medical Association, in one of its most successful reports, deplored the system by which surgeons treated their cases to a certain point and then handed them on to masseuses and physiotherapists, so that surgeons knew nothing of the end and physiotherapists knew nothing of the beginning. Under no circumstances must the orthopaedic surgeon "be freed from anxieties about the final stages of treatment." It was exactly this freedom from anxiety which accounted for the deplorable results of fracture treatment in former days.

These are not the arguments by which to support the survival of physical medicine. Physical medicine will survive, but not as we knew it in the past. It is a part of orthopaedic treatment which begins on the first day that an injury is sustained, and continues throughout every phase of treatment. It is so closely bound up with other orthopaedic measures that it cannot be isolated and separated. Moreover, the blue lights and red lights, and the long waves and short waves, which loomed so prominently in the past, will be relegated to their proper place. Massage and heat will no longer be prescribed as a treatment, but simply as a prelude to the patient's own activity, which is the essential treatment. The future of physical medicine is assured when the physical medicine specialist concentrates on the patient rather than on the apparatus, and more particularly when he concentrates on the mentality of the patient and the psychological reactions which are hindering his physical recovery. A medical officer may well devote his attention to this non-operative aspect of orthopaedic surgery, and thereby earn the title of "orthopaedic physician." His training will be no less lengthy than that of his surgical colleague, his knowledge of bone and joint pathology no less profound, his ability in diagnosis, in manipulative technique, and in the use of plaster no less complete. He may have no gift of operative skill, but he will have the gift of a personality which encourages, stimulates, and inspires his patients. A few medical officers with this experience and ability are already at work in rehabilitation centres in the Services and in the E.M.S. We believe that they are the physical medicine experts or "orthopaedic physicians" of the future.—We are, etc.,

T. P. McMURRAY, Liverpool. R. STIRLING, Edinburgh.
H. J. SEDDON, Oxford. W. GISSANE, London.
R. WATSON-JONES, Liverpool. C. IRWIN, Newcastle.
H. O. CLARKE, Manchester. ERIC LLOYD, London.

President and Secretary of the British Orthopaedic Association, and Chairman and members of the Standing Committee on Fractures.

SIR,—Your annotation on "Physical Medicine, Orthopaedics, and the Services" contains so much which is ill informed and even prejudiced that it cannot be allowed to pass unchallenged. The scope of the practice of orthopaedic surgery was admirably defined by the late Sir Robert Jones for the guidance of his disciples in the early years after the war of 1914-18. The definition was as follows: "The treatment by manipulation, operation, re-education, and rehabilitation, of the injuries and diseases of the locomotor system." Though stated in terms relating primarily to therapeutics, this definition embodied the dual conception of orthopaedic surgery (1) as an integral part of surgery as a whole; and (2) as an independent clinical art and science *(orthopaedics)*, intimately related to the practice of preventive medicine and to the problems of physical education and industrial welfare. To this must be added that in his chosen field the orthopaedic surgeon, as a clinician, acts as a court of first instance, collaborating freely with other colleagues when collateral evidence is required for accurate diagnosis.

In his responsibility to the patient the orthopaedic surgeon's practice is based on the principle of *unity of control* throughout all phases of treatment to the final goal of maximum recovery of function. This principle has been widely accepted as one of the essential features of the modern organized fracture department (B.M.A. Fracture Commission, 1935: Interdepartmental Committee's Report, 1939).

Many, though not all, of the measures included under the term "physical medicine" are thus an integral part of the therapeutic armamentarium of the orthopaedic surgeon. Both in his private clinic and in his hospital service the orthopaedic surgeon chooses the type of physical treatment suitable for his patient, prescribes in detail to the trained masseuse who forms part of his team, and controls such treatment throughout. The writer of your annotation must realize that there will be no withdrawal from this position.

Space does not permit me here to trace the evolution of physical medicine, which in its early beginnings owed much to the practice and teaching of the orthopaedic surgeon of past generations. In Germany, even to-day, the orthopaedic surgeon could be better described by the term "orthopaedic physician," for his practice is founded on a combination of minor operative procedures, the extensive use of plaster, splints, and appliances, massage, mechanotherapy, and gymnastic exercises. At the present time there are in Great Britain, among the senior orthopaedic surgeons, a number who have had many years' experience in the direction of departments of physical medicine. I myself founded and directed for twenty years the department of physiotherapy and its associated school of massage at the Ancoats Hospital, Manchester. In the training of the younger orthopaedic surgeon we regard as essential a knowledge not only of the scope but of the practical details of physical treatment. It is thus quite absurd to suggest, as does your annotation, that "the orthopaedic surgeon has inadequate knowledge of the various means employed in physical medicine."

In asserting his right and competence to prescribe and direct physical treatment for his own patients the orthopaedic surgeon recognizes that there is a wide field of medicine, primarily the responsibility of the physician, in which physical methods of treatment play an important part. I need only quote as examples the rheumatic diseases and affections of the nervous system. In this field the general physician, if so disposed, is entitled to sublet his therapeutic rights to specialists in treatment—in my judgment a most unsatisfactory arrangement. But what has actually happened is that in the growth of specialism there has emerged a group of well-trained physicians—working mainly in spas—who, like the orthopaedic surgeons, have found it essential to prescribe and control such physical measures as in their judgment will benefit

their patients. Here we see, in general medicine, the true counterpart of the orthopaedic surgeon in general surgery. So far as I am aware, these specialist physicians have shown no great desire to be labelled simply as specialists in treatment, nor yet to adopt the new title of "orthopaedic physician." If I may venture to prophesy, they are likely to remain content to be known as physicians, consultant in status and responsible both for diagnosis and for treatment in all phases of the diseases which form their chosen field of practice. The orthopaedic physician of the future—if he takes shape in any great numbers, which I doubt—can only be drawn from the ranks of the fully trained orthopaedic surgeons. He will be an individual who for some well-founded reason has decided to relinquish the operative side of his work.—I am, etc.,

Manchester, May 13. HARRY PLATT.

SIR,—Your annotation prompts me to ask your indulgence to discuss a few points raised therein.

You state that one reason why the subject of physical medicine is little comprehended by the profession at large is that the methods used by those who specialize in it do not form a real part of the training of students. Whose is the fault? Certainly not those who practise physical medicine, for they have made persistent efforts to encourage training in physical medicine methods as part of the compulsory general training of students, and failed mainly because of opposition from the medical profession itself. Mainly due to this the gates of the field of quackery have been further opened. Moreover, the field of quackery is by no means confined to physical medicine, as the charge equally affects many medical methods such as vaccine and glandular therapy (see advertisements in daily newspapers). So long as the Law permits general stores to sell medical instruments such as infra-red and ultra-violet lamps with no control over their efficiency, and to advertise their supposed value in pseudo-scientific language which appeals to the public, there will always be quackery. Surely, however, it is unfair to blame those who practise physical medicine and have done all in their power against heavy odds, and with considerable success, to place this branch of medicine on a scientific basis.

Because of lack of compulsory teaching in physical medicine during their student days, general practitioners have no alternative but to depend on medical auxiliaries, and the fact that such highly trained personnel as the members of the Chartered Society and the Society of Physiotherapists exists has done much to aid general practitioners and to limit the use by the profession of those less qualified.

I submit that your statement that there has arisen some dissension between the specialist in physical medicine and the orthopaedic surgeon conveys an erroneous impression. That there may have been dissension between the two in individual cases is probable, as has happened many times before in other medical departments; but to imply that disagreement between the two branches is on such a scale as to hinder progress is a gross exaggeration and unfair to orthopaedic surgeons and physiotherapists alike. I know that the statement has been made, and I am equally aware that it is persistent and difficult to deny, but why I can never understand.

When I addressed a committee meeting at the House of Commons on "Physical Medicine in Wartime" the same charge was made by two of those present, and in spite of my categorical denial both were inclined to persist in their statement. Realizing the seriousness of this belief and to emphasize my denial I appealed to the chairman to support my contention that nothing I had said could be interpreted as meaning that advocates of physical medicine wished to divorce their specialty from orthopaedics. What I did point out was the fallacy that appeared to exist in some quarters—the Ministry of Health among others—that physical medicine is a corollary of all orthopaedic treatments and that only orthopaedic cases benefit by treatment on physical medicine lines, whereas in fact its field of operations covers more or less every branch of medicine. I further pointed out that a physical medicine organization could work in harmony with every medical and surgical unit to which a department is attached, and that all physiotherapists would, as always, loyally co-operate with their colleagues under whom they might be appointed to work. I still maintain that there is no conflict of ideas or actions between the two sections, and it would indeed be unworthy of either if such were so.

As a result of the present system—or perhaps it would be more accurate to say lack of system—much highly trained personnel has been lost, but the worst feature, and one that will certainly have serious repercussions after the war, is the fact that untrained personnel has been allowed to replace them in many instances. This will materially spoil the effective work that has been done by the Chartered Society and the Society of Physiotherapists in training medical auxiliaries, a work which has done so much to place their activities on a more scientific basis than formerly. The sure result will be that after the war many unqualified people will be treating patients with all kinds of apparatus and claiming special qualifications because of their "war work."

The special committee of the British Medical Association to which you refer did onerous and good work before the war and during its early days, but since the appointment of one of its members as Adviser in Physical Medicine to the Ministry of Health its activities have been successfully sterilized, and as an active body it has been practically ignored by the Ministry, chiefly as the result of the adviser having taken a line of his own in his recommendations to the Minister. I had several meetings with the Minister of Health, at which I endeavoured to persuade him to appoint a committee of experts in the various branches of physical medicine, not merely to advise but with power to act under his direction, so as to bring into being an active organization which would ensure the economic and efficient control of physical medicine in all its aspects. The various departments set up would still be in charge of Sector Physiotherapists, and they in their turn would be under the orders of the Group Officers. This committee would be under the chairmanship of a Ministry of Health official appointed by the Minister and would consist of the necessary secretarial staff and an agreed number of selected physiotherapists representing various branches of physical medicine, including those responsible for spa treatment. It was proposed that the committee should meet daily until the organization was complete and in full working order. Such a co-ordinating and controlling committee with power to act would, in the opinion of many of my colleagues, better enable physical medicine efficiently and economically to cope with the enormous work that lies ahead of it than is possible under the present conditions of local control. Such autonomy of *organization* would surely be a great advantage to all the staffs of hospitals, etc., where there are departments for physical medicine treatment.

The Minister was sympathetic and promised that if, after consultation with his advisers, he considered the scheme advisable, he would appoint a committee on these lines. The end-result, however, was the appointment of a purely advisory committee of busy doctors who can only meet at infrequent intervals, and have no power to see that their recommendations are carried out. In a leading article in a recent number of the *British Journal of Physical Medicine* the paucity of news about this committee was referred to, and it was stated that "unless there is a sudden and remarkable change in the situation we shall be forced to conclude that the committee is a failure."

That there is much dissatisfaction over the present position of physical medicine so far as the different Government organizations are concerned is certain; but it would appear to be almost hopeless to expect improvement mainly because many of those who are practising physical medicine to-day, although they give damning evidence of inefficiency in private, yet express reluctance to make any formal protest in an effort to get better conditions. In all my discussions with the Minister of Health this was an obstacle which it was practically impossible to surmount.—I am, etc.,

London, W.1, May 13. MORTON SMART.

Rehabilitation of the Injured

SIR,—I have read with interest Mr. E. A. Nicoll's article on "Rehabilitation of the Injured" (April 5, p. 501) and the subsequent correspondence about it. It occurs to me that there is a danger of confusing the issue by the wrong use of words. The increasing tendency to confine the meaning of "rehabilitation" within the narrowest limits is, I think, dangerous: in my view it is to miss the whole significance of the term. The ultimate objective of the accident-disabled must be, for his own sake and the nation's, economic rehabilitation—preferably, of course, by means of complete restoration of

function, but, failing that, then by whatever alternative method can be afforded him. A rehabilitation centre should therefore include the whole range of activities which may be necessary to enable the individual to resume his place in the labour market, either as an able-bodied man or on equal terms with the able-bodied. Occupational therapy, physiotherapy, controlled recreational activity, and technical training all have their place in the process, the various component parts of which are closely interdependent. It may be true, as one of your correspondents says, that no injured workman can be regarded as "recovered" until he can resume his original employment; but "rehabilitation" connotes much wider possibilities. For example, A. recovers completely from his injury and resumes his original employment. B. loses an arm, but, after being fitted with a specially designed attachment and given a short period of re-education, can also resume his employment. C., being unable to do this, is, after training, discharged to new employment, where he can earn more than in his original job. Can it be said that of these three only one has been rehabilitated? Direct contact between surgeon and patient and the knowledge that recovery will come by the man's own efforts are equally important for all cases. The rehabilitation centre must be closely associated on the one hand with the hospital when the injured man comes and on the other with the industrial field to which he is being fitted to return.

Experience shows that remedial work for patients capable of complete recovery and training for the permanently disabled can be carried on under one roof, with advantage to both categories for several reasons: the psychological effect is good on each side; the training workshops furnish excellent scope for the activities of the remedial department; and the various facilities provided in the latter are equally needed by the permanently disabled, prior to or concurrently with training.

Unfortunately the out-of-date theory that vocational training means long-term craft-training with employment at the end of it dependent on sheltered conditions or the philanthropic appeal still persists in many minds. Modern methods of short-term training for industrial employment have altered the whole position, as may be indicated by the fact that the Munitions Training Scheme of the Ministry of Labour and National Service now includes a Disabled Section.

A chain of rehabilitation centres throughout the country equipped to give the maximum opportunity to temporarily and permanently disabled workers alike is an urgent need. In this connexion we should do well to consider the American methods in two respects. In the United States the word "rehabilitation" covers all aspects of the economic restoration of the disabled, and one Government Department alone—the Federal Rehabilitation Board—is concerned.—I am, etc.,

Exeter, May 6. GEORGIANA BULLER.

The Mobile Unit and Early Care of Casualties

SIR,—Since I was medical officer in charge of a London mobile unit during most of the air attacks last autumn and winter, and in view of the heavy share of incidents occurring in this borough, my experiences and suggestions in the present discussion on mobile units and casualty treatment might be of value. Recently the unit has been transferred to the control of one of the local hospitals, and I have no official knowledge of its functioning since then.

Very early on I arrived at some broad conclusions. (1) Seldom, if ever, was it either possible or necessary to set up an improvised first-aid post as originally envisaged by the Ministry of Health. The extensive devastation destroyed previously allocated "setting-up" points, while the flooded streets and difficulty of screening lights rendered the original ideas valueless. (2) In common with other units we were either arriving late at incidents from which casualties had already been dispatched or were not called out to incidents requiring the services of a unit. (3) It was usually unnecessary to take out the whole unit on a first call, and a car with doctor, nurse, and driver was very often sufficient.

In analysing these observations it is obvious that the organization responsible for calling out these services must be re-examined. Unless one is on the spot it is difficult to appreciate the indecision which exists during the early stages of an incident. If the strength of a chain be dependent on its weakest link, then indeed the magnificent chain of A.R.P. service hangs on a very rusty link—the express warden's report. As others agree, it is in this that the fault for delay or failure in calling out services is found. One cannot blame these men, exposed to conditions strange and terrifying. Even in a heavily bombed district a local warden can seldom have been present at more than two or three large incidents. In consequence his rapid summing-up errs in judgment, he often forgets the existence of a mobile unit, and when the latter, after an appreciable time, is called out it is usually too late—the damage in handling and shifting cases has already occurred.

How, then, can this be remedied, as indeed it must, for in my own opinion a large proportion of those who died from shock would stand a reasonably better chance of survival if things could be otherwise arranged. The solution is obvious. The authorities have overlooked what must be by now the most experienced body of emergency casualty workers—the stretcher parties. The squad leaders I have found, as a rule, reliable, well trained, cool-headed in action, and with sound common sense. They are accustomed to incidents and know the worth of a mobile unit. I suggest that at any incident the leader of the first stretcher car on the scene should report back to Control if a doctor or unit is necessary; in that way a medical officer would be on the spot when ambulances arrive, to help by sorting cases, administering morphine, and generally supervising disposal. If there is no further need for his presence a message from Control to the incident officer would inform him where he is next required.

We have been told that this would be risking the doctor and unit unnecessarily. I feel that such an attitude of mind is resented, and rightly so, by stretcher parties. They are called out, often to no purpose, in the heaviest raid. A doctor on the scene improves their morale, and he can assume responsibility if necessary, and this makes them much more efficient. If this measure were taken we would surely not have casualties brought in "screaming with pain," as referred to in recent articles. I have often given up to 1½ grains of morphine to ease patients and make them comfortable at an incident. Immediate treatment of this type would materially reduce the danger of severe shock, at present so real. The battle for the lives of casualties may be determined by efficient treatment right from the outset. A ratio of 30,000 killed to 40,000 wounded is unduly high. During the last war, I understand, the consultants were all in favour of an absolute minimum being done in the forward positions and leaving all work for the base hospitals. When, as a result of the rising mortality and in spite of consultant opposition, more freedom was given to the junior medical officers in the front areas, the figures improved. We are learning this lesson again here.

Certain theoretical and practical points must be appreciated if any improvement is to result.

(1) The fall in blood volume and haemoconcentration is the important cause of secondary shock. (2) This fall precedes by many hours the fall in blood pressure; this latter is a comparatively late effect of shock, and may still be high when the condition of shock is well-nigh mortal. (3) Bayliss and Cannon have shown that the onset of experimental shock occurs in twenty minutes after trauma. (4) Krogh (*Anatomy and Physiology of the Capillaries*) states that temporary oxygen lack (due to deficient circulation) will cause irreversible stasis in the capillaries in fifteen minutes. (5) The sooner one can operate on badly mangled cases the better the survival rate. In the last war, when such cases were dealt with within three hours, the mortality was 11%; when left for nine hours it rose to 75%. (6) In the early stages simple treatment such as provision of warmth and fluid will maintain the circulation; in the late stages even intravenous blood or plasma will pass out of the blood vessels. (7) In the first period of shock, morphine, even in large doses, by relieving pain and anxiety, will help to improve the patient's condition; in the later stages it is theoretically unsound, for by depressing the respiratory centre it increases the oxygen deficiency of the capillaries, and hence their permeability. (8) Pitressin, which theoretically causes capillary contraction, if administered early might be of value. (9) The early treatment of minor factors, such as cold, will improve a patient's condition considerably.

At present we are doing little to benefit by early experiences, for it is in the first link that a great deal can be done. Two thin blankets per stretcher as provided to stretcher parties at the moment are quite inadequate to keep a patient warm, who is often shivering while being shifted. There is no provision of hot-water bottles or drinks for casualties in the early stages. By arranging for supplies of hot glucose-saline to be taken out by stretcher parties (and this can easily be done) the

administration of fluids by the mouth in the early stages, by restoring blood volume before absorption via the mucous membrane of the gut fails, will prevent the onset of secondary shock. These measures, combined with the early attendance of a medical officer or a mobile unit on the scene, will greatly help us to improve our figures.—I am, etc.,

E. CRONIN.

April 27.

Sulphapyridine and Suppression of Urine

SIR,—The recent correspondence on suppression of urine following crush injury, and in particular references to its occurrence in cases which have undergone sulphapyridine treatment, prompt me to mention the following case.

A young woman had been under treatment for a few months with sulphapyridine in moderate doses daily. I stopped the drug, and after an interval of three to four weeks administered 1 c.cm. of a bacillary emulsion intravenously. This produced the desired rise in temperature, and forty-eight hours later sulphapyridine was given in doses of 3 grammes daily. The next day the patient complained of sickness and pain, with tenderness referred across the abdomen. There was no frequency or dysuria, no rise in pulse or temperature. I ascribed the upset to the sulphapyridine and stopped the drug, but the pain became slowly worse, and the tenderness extended round into the flank, most marked on the right side—almost suggesting appendicitis, but in a zone higher up. There was no symptom of urinary disorder up to forty-eight hours after the commencement of the sulphapyridine, but after that time no more urine was passed.

The next day the bladder was empty, heat was applied to the loins and lower abdomen, and later a catheter was passed without result. After three days' anuria I transferred the case to hospital, and in accordance with the suggestion of the Edinburgh school commenced intravenous sodium sulphate in glucose-saline by continuous drip.

On admission the general condition of the patient was remarkably good. There was some pain in the back, the right side tenderness had increased, and there was some abdominal distension, which gave rise to discomfort. There was no headache and no oedema; the tongue was remarkably clean and moist. Pulse 80; temperature 97.4°; blood pressure 165/100. During the next forty-eight hours she received 2,500 c.cm. of the infusion, and at the end of this time the patient thought she had passed some urine, but nothing could be seen. A catheter was introduced, and in a few hours 2 oz. of blood-stained urine collected. The first urine passed for five days was blood-stained; specific gravity 1020, albumin + +, acetone +. No laboratory facilities were available, so fuller investigation was not made.

The general condition of the patient was still reasonably good, though she was greatly distressed by the pain in the kidney region and by the abdominal distension. The next day distress was more marked and only 4 oz. of urine was passed; this was not now blood-stained. Free fluid was noticed in the abdomen and pleural cavities. Blood pressure had risen to 190/110. The urinary output increased to two pints on the following day, but the pain and distress were unchanged. Some oedema of the sacral region and ankles was noticed. The pulse rate rose to 130 and the respiration was embarrassed by the abdominal distension. Seven pints of free fluid were slowly aspirated from the peritoneal cavity.

For the next two days the urinary output was only 10 oz. and 12 oz., and little change could be observed in the patient's condition. A large tender mass, the size of a large grapefruit, evidently kidney, was palpable in the right kidney region. This mass gradually diminished and the urinary output returned to normal. There were, however, some occasional rigors in the uneven convalescence, but the urine is now normal in quantity and contains no abnormal constituents.

It is now five weeks since the onset; the right kidney is no longer palpable, and the patient is feeling very well indeed, with blood pressure 130/75.

On admission to hospital I was tempted to recommend passing a ureteral catheter, but after consultation it was decided not to do so lest we change what might have been a temporary anuria to a more permanent one, especially as the patient's general condition was so good. *X*-ray examination did not show presence of a calculus.—I am, etc.,

Northallerton, April 29. H. G. HANAN.

Cause of Appendicitis

SIR,—Dr. C. Leleu (May 3, p. 689) agrees that the cause of appendicitis is trauma. I have never suggested that trauma occurs in the infantile appendix only, but that the initial trauma (the starting-point of a train of morbidity which culminates in an acute attack) probably occurs when the appendix like the rest of the tissues is tender and specially vulnerable, and when it is too often exposed to trauma from foreign bodies in the shape of ill-digested or improper food. That such bodies, frequently passing in and out of the appendix or lodging in it, may start the morbid process (which appears in various forms) is at least a reasonable supposition.

He tells us that the appendix he had just removed was "normal except that it contained a coprolith." Surely that appendix was abnormal or morbid. The presence of the coprolith was evidence of morbidity arising from trauma which may have occurred many years before, possibly in infancy, and at any moment it might have inflicted further trauma resulting in an acute attack. His patient suffered from appendicular colic, and I believe it is generally agreed that this or some other evidence of morbidity can usually be found either in the clinical history or in the pathological examination (or both) if carefully sought. What exactly are the attacks of colic (wind) to which artificially fed babies are so prone? A careful study of the symptoms (the sudden onset and sudden relief, the obvious spasms or visible peristalsis, etc.) suggests the passage of a foreign body into and out of the appendix as the most reasonable explanation. Recently someone reported the safe removal of the appendix in a baby a few weeks old who was suffering from appendicitis. (I'm sorry I cannot find the report.) If only he had given a clinical history and detailed account of the pathological findings he might have advanced our knowledge considerably. A systematic properly organized investigation on these and other lines is long overdue; no one man could possibly deal with all the different kinds of evidence which should be collected.—I am, etc.,

Ambleside, May 5. J. PRICE WILLIAMS.

Certificates by Practitioners

SIR,—In connexion with the alleged laxity in issue of certificates by general practitioners, I am sure that the whole position could be clarified if an official ruling was given concerning certificates in special cases. The General Medical Council should prohibit the issue of certificates of the sort mentioned by Dr. J. B. Wrathall Rowe. Such a ban would be welcomed by the profession since much friction between doctor and patient could be avoided if a refusal could be supported by an official statement.

The majority of the profession are anxious to avoid trouble between "works" doctors and general practitioners, but it must be realized that many doctors have no experience of factory conditions, and, conversely, the difficulties of general practice are not always appreciated by doctors working for industrial concerns. The tendency of firms to demand a medical certificate from an employee who takes time off from work to see his doctor is apt to cause irritation to the practitioner, who is already harassed by a multiplicity of forms.

I have known many valuable hours wasted when patients have been sent away to obtain a medical certificate before being allowed to start work. In some instances the cause of the patient's absence has been as clear to the employer as to a doctor, and a certificate is only required to meet the firm's regulations. I refer to such conditions as haemorrhage following teeth extraction and contusions resulting from falls. In the former instance bleeding has often stopped when the doctor arrives, and there may be little evidence that excessive haemorrhage has occurred as patients are prone to exaggerate the severity of the condition. Is a certificate stating that the patient was unable to work by reason of "haemorrhage following extractions" justified on the scanty evidence available? Remember that the certificate relates to the time immediately preceding the visit, and that failure to issue such a certificate may cause suspension of the patient's salary.

I consider that certificates can be put into three classes: *Class 1.*—No doubt exists of a patient's inability to work—for example, concussion, fractured femur, etc. *Class 2.*—Where a patient's inability to perform certain duties is largely a question of opinion. In cases where the doctor is not acquainted

with the special conditions of work he should refer the patient to the works doctor without comment, but more difficulty exists with fire-watching. Patients sometimes claim exemption on grounds of bronchitis, peptic ulcer, and neurasthenia. Although the honesty of the profession to protect the national interests involved must ultimately be relied upon, some official guidance would be helpful in dealing with a problem where opinions may differ so widely. *Class 3.*—"Nuisance" certificates. In this class I include "cheap milk" forms, certificates recommending reduced rates of travel to see evacuated children, and requests for certificates relating to sick relatives of men serving in H.M. Forces in order to obtain extra leave.—I am, etc.,

Welling, Kent, May 10. H. G HOWITT.

SIR,—It is common knowledge that medical certification by general practitioners is often lenient. As general practitioners are in a much closer relationship with their patients than their colleagues who hold official positions, it cannot be otherwise. They act not merely as judge and jury, but also as friends and advisers. This was recognized at the inception of the National Health Insurance Act, and the ancillary Regional Medical Service was originated to counteract it, with success. Certification for purposes other than National Health Insurance has no such counterweight, but general practitioners cannot be blamed for that.

As for the certificate exemplified by your correspondent, Dr. Wrathall Rowe (May 10, p. 732), I see in it nothing "ludicrous in the extreme," or even ludicrous. Apart from the operative word "unable" in the certificate—obviously incorrect—the meaning to me is abundantly clear—namely, that X's wife is so liable to attacks of nervous distress as to make it inadvisable for her to be alone at night. And who should know this better than X himself and his doctor? Surely not Dr. Rowe. I could, with truth, issue similar certificates to two or three patients in my own practice.

Criticism of general practitioners seems to come easily to the official practitioners—so easily that I once indulged in it myself. Successfully to conduct and to hold a general practice is far from easy, and only those who have had this experience can fully realize its inherent difficulties—difficulties not encountered in other branches of the profession. Laxity in the mere wording of certificates there may be, but a general practitioner may issue hundreds of certificates in a week. Leniency in the opinions expressed there may be, but then there are no absolute criteria for fitness or unfitness for such work as fire-watching, night-duty, and shift work. And general practitioners are not alone to blame for leniency; blame, rather, those factors and forces, quite outside their control but quite understandable by them, which tend so much to modify and to implement their actions. No present regulations or rules will, I think, alter this state of affairs.

As for the Warning Notice issued by the General Medical Council, this surely applies to deliberate untruthfulness: very different from leniency, or laxity.—I am, etc.,

Barnsley, May 12. S. CURRY.

Treatment of Diphtheria

SIR,—I am trying out diphtheria serum and sulphapyridine together, and I believe the latter reinforces the former to some extent. If there are any haemolytic streptococci in a throat, as well as diphtheroids, it would certainly scotch them: and it may be also that various organisms in the mouth, non-pathogenic in health, become pathogenic when diphtheria has sufficiently decreased the resistance of the tissues. So sulphapyridine would probably scotch them too. I think proper controlled experiments should be made on serum and sulphapyridine in some hospital where research is carried out.

To my way of thinking the full treatment for diphtheria should be: serum and sulphapyridine, glucose, vitamin B, vitamin C., I also think that diphtheria patients should not be kept rigorously lying flat on their backs. If they like to turn on to their sides, draw up their legs, or stretch out the arms, I think they should be allowed to do so, since the movements probably keep up the tone of the heart muscle. Also mucus would not tend to accumulate in the bronchi, and the blood would not tend to gravitate to the posterior surfaces of the lungs.

My idea of diphtheritic paralysis is that the various portions of the C.N.S. are struck at once but that there are different latent periods before the paralysis shows itself. I think that respiratory paralysis has a longer latent period than palatal paralysis, and that merely resting neither prevents the paralysis nor stops it spreading. If that is so, then one might just as well move about. Comments will be much appreciated.—I am, etc.,

Liverpool, April 30. FLORENCE M. E. DAVIES.

"Bureaucratic Surgery"

SIR,—Is not the question of "who shall treat" wounds of the scalp, or indeed primarily treat other wounds of special regions, largely a problem of transport and distribution? One admits that they will be treated with 100% efficiency in the neurosurgical centres; also that even in peace they are very inefficiently treated in places where one would look for better things. Can, however, all or nearly all the cases reach such centres in time for the primary toilet which is so essential? Only to-day did a case reach me which had sustained a scalp wound fifty-seven hours previously and had been in another hospital. The wound was concealed by a mass of clot and extraneous dirt covered by a dressing of gauze. If the patient took all this time to get out of the danger zone how could he hope to reach any special centre in time for adequate treatment?

Are the neurosurgeons not in danger of committing the error of condemning patients to wait until only a bad result is possible by attempting to prevent earlier treatment, perhaps not quite so good as the centre would offer could the victim reach them in time, but more adequate under the circumstances? It might be argued that my case ought to have been sent to a neurosurgical centre rather than here. So it might had not bombs been dropping at inconvenient intervals.—I am, etc.,

May 10. W. A. MACKAY.

Cleansing Eyes of Gas at First-aid Posts

SIR,—The problem of the gas cleansing of eyes at first-aid posts seems to call for special attention. The official practice is to douche eyes at the entry side of the gas cleansing unit. The usual routine is: (1) douche eyes, (2) bleach, (3) rinse, (4) soap (the most important part of the operation), (5) rinse, and (6) dry.

I suggest an improved technique (modified to suit local conditions) as follows: (1) Patient stands under shower with eyes closed and his face and hands are rinsed; (2) bleach, (3) rinse, (4) soap, (5) rinse, (6) douche eyes. The object of this procedure is to avoid further contamination by the person treating the eyes on the clean side of the showers.—I am, etc.,

G. C. F. ROE,
May 12. Medical Officer of Health, Halifax.

Testing Night Vision

SIR,—My attention has been drawn to the *Journal* of April 26 (p. 636), in which you include a description by Mr. N. Bishop Harman of a test for night vision which I have designed and which is now being marketed by Sir Isaac Pitman and Sons. In the course of this account some criticisms are made which, although I do not consider them to be valid, I do not wish to comment on here, with one exception. This exception is a statement of fact which, if true, would make the test practically useless; it is, however, incorrect. The test consists of a faint light source provided by a disk of radium luminous compound which illuminates a series of cards of a broken circle of various degrees of grey printed on a black background. In your review the following statement occurs: "It is evident that the radium illumination may be variable. There can be nothing standard about it." If this were true, it would mean that on one occasion an observer would be able to see one card in the series, and on another occasion he would be able to read a different card, so that the results obtained would mean nothing at all. In practice, each disk has been selected so as to provide the proper level of illumination when first sent out and does not subsequently diminish by more than 25% during the next two years. This change is quite unimportant, and at the end of two years a new disk can be purchased. Provided the disk is not misused, and provided the directions are followed as to opening the test in the dark, no other changes in intensity will occur, and the source is, in

fact, a standard source. In support of this, it may be mentioned that the same material is now used as a light source in a standard gauge for testing the level of A.R.P. lighting.

The test does, therefore, satisfy the need, indicated by your reviewer, for a "standard test that could be set up by an ophthalmic surgeon for himself, and yet would be the same for all," and I should appreciate it if you would make a correction to this effect in your *Journal*.—I am, etc.,

London, S.W.7, May 16. W. D. WRIGHT.

Reactions after Transfusion of Stored Blood

SIR,—Although the experience with stored blood at St. James's Hospital, Leeds, is as yet relatively small, sufficient evidence is available to indicate that this material caused no detriment to the patients. Our records were examined by the method of Dr. Eric Jewesbury (May 3, p. 663), with the following results:

Fresh blood was alone available during the period 28/10/39 to 12/12/40, when 225 transfusions, requiring 298 bottles of blood, were administered. The reactions observed were: Grade III, 10 or 4.4%; Grade II, 16 or 7.1 %; and Grade I, 17 or 7.6%. Thus there were in all 43 or 19.1% of reactions, of which 26 or 11.5% were severe. The transfusions were conducted by one or other of twelve medical officers.

Stored blood provided by the No. 2 Regional Transfusion Centre was used from 13/12/40 to 30/4/41, and on the average it was stored for approximately seven days. During this period there were 160 transfusions, requiring 216 bottles of blood. The reactions observed were: Grade III, 5 or 3.1%; Grade II, 6 or 3.8%; and Grade I, 7 or 4.4%—a total incidence of 18 or 11.3%, of which 11 or 6.9% were severe. These transfusions were conducted by one or other of fifteen medical officers of varying experience. It is pertinent to comment, also, concerning the Grade III reactions, that four of the patients each received a pint of blood in from 1¾ to 3¼ hours, when a slower rate of administration was indicated. The fifth patient had undergone evacuation of the uterus for incomplete septic abortion prior to transfusion.

It is reasonable to claim that if stored blood be unsafe our records could not have shown this distinct reduction in reaction rate following a change from the use of fresh to that of stored blood. Our experience fully demonstrates the advantages, by way of time and labour saved, of a satisfactory supply of stored blood.—I am, etc.,

Leeds, May 16. CYRIL POLSON.

Treatment of Burns

SIR,—I have read with considerable alarm the letter of Mr. Rainsford Mowlem (May 3, p. 686) in which he dismisses the use of tannic acid in the contemptuous words—"Perhaps it has its place in some burns."

In burns of small areas perhaps Mr. Mowlem's weapon of the future may have its place, but even here it has been shown in recent papers by Cohen, and by Ross and Hulbert, that if tanning is properly carried out it compares favourably with any other method. In large areas, however, the patient's very life is at stake if tanning is not carried out. Why is it that tannic acid so completely replaced all other methods after its introduction in 1925 by Davidson? Simply because it reduced the appalling mortality of burns from over 20% to under 4%. It is the ability of tanning to prevent secondary shock that made the remarkable reduction of mortality possible. It is why tanning very definitely has its place in the treatment of burns.—I am, etc.,

London, E.9, May 7. W. D. PARK, F.R.C.S.

Post-war Medical Education in London

SIR,—The article by Mr. Somerville Hastings (May 3, p. 678) prompts me to put forward a suggestion for the present and future training of medical students complementary to those made by him. Towards the end of last year the Norfolk and Norwich Hospital offered to the deans of several London medical schools facilities for students to carry out part of their clinical training. This offer was accepted, and so far twelve students, most of them from one hospital, have been sent. This one hospital has arranged to send students at regular intervals for the duration o. the war. In addition, under a more recent arrangement, three students are being appointed for three-month periods as student house officers, acting under supervision. The advantage of this arrangement —to the students of the additional experience and to this hospital during the present shortage of qualified residents—is obvious. All the students have noticed and appreciated the quality and amount of clinical material, of which the comparatively small number of students have been able to take full advantage.

The Norfolk and Norwich Hospital has 398 beds and works in close collaboration with the Jenny Lind Hospital for Children of 100 beds. It has large out-patient clinics with fully equipped ancillary departments, and is staffed by a consultant honorary medical staff experienced in teaching. It is clear that in similar hospitals all over the country a large amount of clinical material is available which could be used for the training of students, and the purpose of this letter is to suggest that after the war students should continue to attend provincial hospitals as a recognized part of their clinical training. It would not be difficult for arrangements to be made between the London teaching schools and approved provincial hospitals to second students for an agreed part of their clinical training, and I am sure that students would find such an arrangement of great value to them.—I am, etc.,

Norwich, May 17. MICHAEL W. BULMAN.

Medical Planning Commission

SIR,—The correspondence in the *Journal* on the Medical Planning Commission and collateral subjects seems to me to point to the necessity for a radical candid and entirely objective discussion of what, for many of us, is a fundamental article of faith—namely, the right of the patient to choose his own doctor. In the fight over National Health Insurance the insistence of the profession on this point undoubtedly had the support of the public and was largely instrumental in securing fundamental alterations in the original scheme.

I need not say to anyone who knows me what my opinion was and is. I stand for the right to choose my own doctor for myself, and believe it to be in the general interest. But as an honest man I cannot shut my eyes to several tendencies which seem to suggest that the public no longer lays the stress on it that it did a generation ago. First, there is the greatly increased tendency to resort to hospitals, where there is no choice. When I was in practice I had the greatest difficulty in persuading patients to go near a hospital, though probably the main reason was fear of what might happen rather than objection to a strange doctor. Then there is the growth of social medicine: patients, particularly women and children, have got the habit of resorting to welfare and other centres, where there is no choice. Thirdly, there is the significant and to me the extremely disappointing and disconcerting fact that free choice is so little used in National Health Insurance. In normal times the number of changes of doctor never faintly resembled what happens in private practice. No doctor can possibly please all his patients, and in private practice they simply leave him. Granting that the insurance regulations make transfer much more difficult than in private practice, the statistics of change make it difficult for me to believe that the people concerned are as appreciative of their rights as I always hoped they would be. Fourthly, the passive way in which insured persons allow themselves to be transferred when a practice is sold seems to me significant.

Now, if these tendencies, and others I could adduce, mean that the public is attaching less and less importance to the value of their right to exercise their own choice, the significance of this tendency can hardly be over-estimated in the discussions now going on. Any medical service must be based on the best interests of the patient. If the patient is now only anxious to be given the best advice and treatment, and more or less indifferent where he gets it, the hands of those who want a kind of medical civil service are strengthened.

I firmly believe that a candid discussion of this fundamental aspect of medical practice should be one of the first concerns of the Medical Planning Commission, and as that body is bound to be guided by what it believes the public want and should have, I hope that many men of large and current experience in general practice will state their opinion. What we *should* have, of course, is the opinion of the patients themselves, but I know of no way of getting this except through the voice of those who are in close touch with them. We want candid opinions from men of experience who have

thought over the tendencies to which I have drawn attention. If there should be a consensus of opinion that the people no longer value the choice of their own doctor, I should regard it as a retrograde tendency, but should bow to it as a regrettable necessity. If, on the other hand, we could be assured that the old regard for the family doctor still persists, it must greatly influence any decisions arrived at by the M.P.C. and by any Government. The question seems to me to underlie the whole discussion.—I am, etc.,

Henley-on-Thames, May 12. ALFRED COX.

DR. A. D. FRAZER, honorary secretary of the Nottingham Division, British Medical Association, sends for publication a copy of the following letter written to Dr. G. G. Genge, Honorary Secretary of the Croydon Medical and Panel Committee, in reply to that committee's circular of April 10 regarding the Medical Planning Commission:

Dear Sir,—Your letter of the 10th inst. was read and discussed at the annual meeting of the Nottingham Division, held on Thursday, 24th inst. The meeting decided that it could not agree with your Committee's resolution to "dissociate itself, in advance, from any findings of the Medical Planning Commission, as at present constituted." In the view of the meeting the Commission should be given the opportunity of doing its work as a "fact-finding body." Suggestions and plans arising from the facts thus found could then be discussed at Division/Branch meetings throughout the country and at meetings of all practitioners in each area, thus affording every practitioner the opportunity of expressing his views and taking his share in formulating any desired changes.—Yours faithfully,

Nottingham, April 29. (Sgd.) A. D. FRAZER.

Reactions after Ethanolamine Oleate Injections

SIR,—Several preparations of the newest sclerosing agent ethanolamine oleate are now on the market, and I note that the advertisements and pamphlets all seem to imply that as regards reactions this substance is trouble-free. Admittedly reactions are probably very rare, but an experience of mine may prove of interest.

A woman of 38 was seen two years ago and had six 2 c.cm. injections of sod. morrhuate. Following the last injection she reported a profuse urticaria, and then remarked that she had it very mildly after a previous injection. She was next seen a few months ago with some veins in the other leg, and since ethanolamine oleate was then definitely advertised as being reaction-free some was obtained. Before it came a dose of quinine urethane was administered with no untoward effect. A dose of 1.5 c.cm. ethanolamine oleate was injected, and she reported that "about half an hour later my face was like a beetroot, but it soon passed"; actually she did not herself attribute it to the injection. Having reread the literature I gave an injection of 1 c.cm. with no reaction; next 1.5 c.cm. was inserted and severe anaphylaxis followed at once, which slowly improved with the usual treatment. The result on the veins was, fortunately, all that could be desired.

It would appear to me, therefore, that this substance can produce reactions, and that care should be exercised when changing from sod. morrhuate for this reason. I may say that this particular bottle was subsequently used on other patients with no reaction.—I am, etc.,

May 1. F. J. BRICE, M.B.

Vitamin C from Rose-hips

SIR,—In its April *Bulletin* the Children's Nutrition Council reminds us that we must attend to our supplies of vitamin C for baby feeding. They recommend that the whole crop of blackcurrants in the country should be reserved for the production of a purée to replace orange juice for infants. For the prevention of infantile scurvy one ounce daily (estimated to contain 30 mg. of the vitamin) would be required. Such a purée would be canned, and the contents are reported to remain fresh for a fortnight after the tin is opened.

It is stated that carrot juice is not a satisfactory source of the vitamin, and it is implied that although some varieties of turnip are a good source, this is not true of all varieties. The recommendations which I have seen for the extraction of turnip juice are two: the first is to cover the sliced root with sugar; the second is boiling. Miss M. Olliver has recently stated that if the root is sliced thinly and boiled for half an hour "extraction was great and destruction by boiling was very small."

All these sources have definite limitations, if not drawbacks. In Denmark the vitamin C which is used in children's hospitals and nursery schools is derived from the rose-hip. I called the attention of the Ministry of Food to this in September of last year, when a large crop of these berries was to be seen in our hedgerows. Prof. Drummond confirmed the high vitamin C content of rose-hips. I understand that a jelly can be prepared from rose-hips without the use of sugar, and that this is palatable and well liked by infants. In Denmark, however, the preparation was a bottled fluid.

We have now a good six months before the new crop of berries will be ready for harvesting. The obvious people to do the conserving are the Women's Institutes, as they are already entrusted with the sister industry of jam-making. Children, through schools, scout troups, and other organizations, could well be enlisted for the harvesting. It remains for the scheme to receive official recognition, together with a simple and effective recipe (as near fool-proof as possible) for the jelly or conserve.

May I be permitted to invite the profession to encourage this little skirmish in practical dietetics?—I am, etc.,

K. E. BARLOW, M.R.C.S., L.R.C.P.

Coventry, May 13.

*** Brief notes on rose-hip jelly were published in the *Journal* of March 29 (p. 500).—ED., *B.M.J.*

Air Embolism from Blast

SIR,—In your issue of January 18 there appeared some articles discussing the effect of high-explosive blast. The term "pulmonary concussion" was used to denote one of its outstanding effects: but as a rule the post-mortem findings have not been sufficient to account for the patient's death.

A possibility which has not been mentioned is that of air embolism. The immediate effect of the explosion is to create a very strong positive pressure in its vicinity, and this would increase the air dissolved in the blood considerably. Subsequently there is a rarefaction of the atmosphere. This would lower the pressure in the lungs below normal and lead to a rapid withdrawal of the previously dissolved air in the blood. Hence there would be a strong tendency for air bubbles to form in the blood and possibly also in some of the tissues, which are especially susceptible, such as the central nervous system. Lastly, the pressure externally stabilizes. This would have the same effect as recompression in caisson disease, and by counteracting the effect of rarefaction drive the air bubbles back into solution. Hence the post-mortem examination might show very few of the typical signs of air embolism.

Trusting that this explanation might be of some value in the elucidation of the condition.—I am, etc.,

Capetown, April 17. S. SCHER, F.R.C.S.

Discission of Secondary Cataract

SIR,—A student, when talking about the most suitable instrument for discission of secondary cataract, said to Ziegler that he thought there was nothing better than the instrument which bore that name. "Oh yes; there is something better—two Zieglers," replied the surgeon. With that remark, and Mr. Bishop Harman's well-described *modus operandi* in your issue of May 3 (p. 687), most of us will agree. However, if we use two needles, it does not necessarily follow that the case will not present difficulties, but these will certainly be less if we use mydricain.—I am, etc.,

London, W.1, May 12. F. E. PRESTON.

Neutrons in the Treatment of Cancer

SIR,—The discussion of the effect of neutrons in cancer (March 22, p. 447) raises an interesting point. As the energy exhibited by a given force is proportional to the resistance which it meets, it should be worth while to determine the effects of the stoppage of all rays passing through tissue by placing metal behind it. Whether the production of reflected rays by a metal screen placed behind tissue be practicable or not, there is no doubt that the arrest of so many rays must cause a great increase in the local exhibition of energy, no matter what the source of the rays may be.—I am, etc.,

Montreal, April 15. RICHARD KERRY.

Adrenal Graft in Addison's Disease

SIR,—Dr. J. J. Conybeare (May 3, p. 688) is perfectly correct in doubting the diagnosis of Addison's disease in a patient without pigmentation. I have seen numerous cases of this condition, but never one without pigmentation of the skin, and particularly of the buccal mucous membrane and tongue.

As a matter of interest, a patient I saw first in 1930 with all the classical signs of the disease and a systolic blood pressure of 75 mm. Hg—and treated with eucortone—is still alive, cheerful, and performs all her household duties. Despite her remarkably good health when I saw her a few weeks ago, she has never lost her pigmentation, though it is markedly paler than it was five years ago.

In my view the prognosis in women should be less unfavourable than in men, if they can be kept alive long enough for their cortical "rests" to take up the function of the adrenal cortex. They have the additional advantage of Marchand's organ in the broad ligament, which is composed almost entirely of cortical tissue.—I am, etc.,

Brookwood, Surrey, May 10. H. M. STANLEY TURNER.

Treatment of Scabies

SIR,—The columns of your *Journal* and its contemporaries continue to publish comment on scabies. Modifications of the older methods and innovations are suggested. Deductions are drawn from inadequate clinical data and empirical findings. Often a small number of cases has been considered. Patients have been observed in favourable circumstances—that is, hospitals, temperate climates, and controlled hygienic surroundings. May it not be worth while for a moment giving thought to certain fundamental facts regarding the invading organism and its "habitat," the human skin?

Scabies is an infection of a delicate tissue with a highly resistive organism depositing eggs therein. In theory it should be easy to find some medicament which rids the human body of the acarus; in practice such solution is not easy, since all known antiparasitics are irritative, and little consideration is given to the manner in which ova are buried and the method by which medicament and vehicle reach them. Lengthy clinical relief may be hoped for if the fully developed acarus is killed, but permanent immunity is unlikely unless all ova are eradicated.

It would appear certain that an ideal therapeutic agent and vehicle will only be found when a procedure has been found which:

1. Entails a mechanical opening, rather than a physico-chemical penetration, of burrows (there is no known wetting agent which permits spread of vehicle along a tunnel);
2. Involves the use of a non-irritant (rotenone derivatives are not likely to fall within this class in the presence of heat, friction, and perspiration; scrotal dermatitis of this origin is highly intractable);
3. Considers the life cycle over at least ten days of the acarus;
4. Utilizes wetting agents to penetrate folds, fissures, and pustules in a manner which paraffin bases do not, but avoids consequent disadvantageous detergent and degreasing after-effect (soaps, alcohols, and emulsion bases all have this drawback);
5. Applies sulphur in a physically non-irritant molecular form (gaseous administration has been found impracticable);
6. Releases medicament from vehicle because of preferential solubility for the aqueous (? oil water emulsion film) terrain of the human skin rather than for its vehicle.

Can we not enlist the co-operation of the entomologist and the physical chemist? Clinicians to date appear to have ignored their existence, to our loss.—I am, etc.,

Manchester, May 16. P. B. MUMFORD, M.D., F.R.C.P.—

Laryngitis in Secondary Syphilis

SIR,—The following case is of some interest, as it depicts secondary syphilis in one of its rarer manifestations—that is, laryngitis.

A soldier, 23 years of age, was sent up by his medical officer to the throat department of the hospital in which I am working. He complained of a hoarse voice of two weeks' duration. There was no past history of hoarseness or loss of voice. The voice was hoarse, strong, and painless. On examination, his pharynx was generally injected. The larynx showed marked hyperaemia and infiltration of the ary-epiglottic folds, and of the mucous membrane over the arytenoids. The vocal cords were not injected; abduction and adduction were normal. There was no secretion anywhere. On the tongue were three superficial ulcers, each about the size of a threepenny-bit, and all situated on the sides of the tongue. Only the surface epithelium was eroded, and the papillae showed up strongly. These ulcers were entirely painless. There was bilateral rubbery enlargement of the cervical glands.

He was sent to the V.D. centre for a general examination and Kahn test. The report was: "History of primary sore some months ago. Typical anal condylomata found; these have been scraped and spirochaetes obtained. Kahn reaction strongly positive." Anti-syphilitic treatment was accordingly started. The ulceration of the tongue vanished at once, and the larynx shows much less infiltration.

The points of interest are: (1) The only complaint was hoarseness; the appearance of the larynx suggested the diagnosis. (2) Mucous patches on the tongue only.—I am, etc.,

Middle East Force.

Methods of Air Disinfection

SIR,—Referring to your annotation on methods of air disinfection (May 3, p. 675), may I mention a simple method which proved effective in the great influenza epidemic of 1918 and in the following years, and which was described in the *Deutsche medizinische Wochenschrift*, 1920, 19. One spread commercial 10% tincture of iodine on a glass or china plate, so that by swaying it here and there it covered the whole surface. The alcohol evaporated quickly, leaving a thin layer of the brownish-red iodine metal. According to the temperature of the atmosphere the iodine disappeared slowly, and the vapour, mixed thoroughly with the air by diffusion, effectively disinfected the space. Possibly the small amount of iodine resorbed by respiration, as is well known, makes the body more resistant against infection.

In order to keep the dust, silicates, etc., bound on the floor, I suggested to the Ministry of Home Security last year that the floors of the shelters should be moistened with a thin layer of linseed oil.

Both of these methods may accomplish the recommendations discussed so eminently in your article about prophylaxis in the shelters.—I am, etc.,

London, W.1, May 12. J. PLESCH.

Measuring Genius

SIR,—From reading your interesting leading article (May 17, p. 756) on Prof. Terman's monumental work one is forced to the inevitable conclusion that, however worthy, the deluded professor has been barking up the wrong tree. If the title is sound, then the whole work is pure bosh; and, alternatively, if the title were altered to "Genetic Studies of Successes and Possessors of Respectable Bank Balances," then most of what is written would undoubtedly hold good.

Success of more than fleeting duration calls for in its devotees most of the qualifications which Prof. Terman thinks the ear-marks of genius—versatility, emotional stability, good health, socially desirable wives, contentment—certainly contentment: one must think what one is doing is worth while—and, above all, sharpness, or rather smartness, of intellect as assessed by the intelligence test.

A genius, on the other hand, in contradistinction to most of us, occasionally thinks for himself and perforce is a bit of an outcast from the clan and consequently undesirable in the psycho-analytical sense; or he must possess a heaven-born gift of intuition, which perhaps is much the same thing.

Now success presages neither of the above attributes, and although in business a little of the latter might conceivably be helpful, in academic spheres even a trace of the former would prove fatal.—I am, etc.,

Thame, Oxon, May 17. E. GRANGER, M.B.

Obituary

GEORGE LOVELL GULLAND, C.M.G.
LL.D., M.D., F.R.C.P.ED.

The death of Prof. Lovell Gulland occurred at his house in Edinburgh on May 4. For some time he had been crippled by arthritis but he had been seriously ill for only a week. He was born in 1862, the son of John Gulland, merchant and magistrate of the City of Edinburgh. His brother, J. W. Gulland, M.P., was for some years Chief Whip of the Liberal Party in the House of Commons. He married the second daughter of the late Prof. Masson of the Chair of English Literature in the University of Edinburgh. His son is Professor of Chemistry in the University of Nottingham, and his daughter is married to Prof. Masson, Vice-Chancellor of the University of Sheffield.

Professor Gulland had a distinguished student career. As an undergraduate he acted for a year as research assistant to Prof. Ray Lankester at University College. He took the degrees of M.A., M.B., and B.Sc. at Edinburgh University. His M.D. thesis on the development of lymphocytes is a classic. In early professional days he was resident physician to the Royal Infirmary and to the Royal Hospital for Sick Children, Edinburgh. Thereafter he became private assistant to the late Sir Thomas Grainger Stewart. He held numerous appointments: physician to the Royal Infirmary, to the Chalmers Memorial Hospital, and to the Royal Victoria Hospital for Tuberculosis. He was principal medical officer to the Scottish Widows' Fund.

Gulland had an enormous teaching experience. He conducted a course of practical instruction on the examination of the chest at the Victoria Hospital. With the late Sir Robert Philip, he held a popular class on methods of diagnosis. His classes on haematology were among the first of their kind and were largely attended. In 1907 he became lecturer on medicine at Surgeons' Hall, and in 1915 he was elected to the chair of medicine in the University. By this time his consulting practice had become enormous. In 1916 he became consulting physician to the Forces at Malta with the rank of colonel. His services were recognized by the award of the C.M.G. He was secretary to the section of medicine at the International Congress of Medicine in London in 1913, and was chairman of the Foreign Guests Committee and of the Section of Medicine at the British Medical Association Meeting in Edinburgh in 1927.

Gulland was a pioneer in haematology. His contributions to its literature were very numerous. He was awarded the Freeland Barbour fellowship for the best work carried out in the laboratory of the Royal College of Physicians within the previous two years, and in 1926 he received the Cullen prize of the College, which is awarded to the Fellow who during the previous four years has made the most important contribution to practical medicine. At a later date he became curator of the College laboratory. Besides numerous magazine articles Prof. Gulland was joint author with Dr. Goodall of *The Blood*, and with Prof. Stanley Davidson of *Pernicious Anaemia*. After his retirement from his Chair and from the staff of the Royal Infirmary he became a manager of that institution and threw himself whole-heartedly into the administration of its affairs.

The great characteristics of Gulland's personality were his boundless energy, his wonderful flow of ideas, his memory, and his mental quickness. It is not generally known that the citizen of Edinburgh, if so minded, can play golf, catch trout, or shoot grouse without crossing the city boundary. It was not uncommon for Gulland in an interval between consultations to get on to his bicycle, find a nook by a pond and start or finish a water-colour sketch. If longer time were available he would ring up a friend and announce, "There is time for nine holes before dinner: what about it?" Unfortunately these intervals became more rare as his work increased, the cycle gave way to the motor car, and relaxation was almost entirely limited to a spring and autumn holiday. Gulland began to suffer from arthritis, and while he remained active till a week before his death he was greatly crippled.

Gulland had no affection for formality or ceremonial. He was a capital business man. He was a dignified and much respected President of the Royal College of Physicians, but "the great occasion" had little appeal for him—except, now and then, to his sense of humour. His teaching was informal and conversational but he gave full value to his audience. In his writing he was a little apt to forget that the ordinary mortal requires such aids as headings and paragraphs. In speaking he had none of the tricks of the orator, but he kept his audience interested, amused, and often amazed at his memory and his wealth of illustration. Gulland was a great asset at informal gatherings. His humour, his mental agility and his willingness to contribute in speech, story or song made him a most agreeable companion. He had a great place in the life of Edinburgh. He was affable and kindly, a delightful host, devoted to his family life and (with every reason) a very proud grandfather.

A. G.

The following personal appreciation is from the pen of another Edinburgh colleague.

The tidings of Prof. Lovell Gulland's death have brought sorrow into the hearts of his former students, colleagues, and countless friends at home and over-seas. Born nearly four score years ago, Gulland had a most distinguished career. As a young physician in Edinburgh he began those pioneer investigations in the research laboratory of the Royal College of Physicians upon the morphology of the blood and blood-forming tissues which entitled him to be styled, in later years, the "doyen of British haematology." It is in large measure upon his work in this sphere that Gulland's world-wide fame rests. Much of his great experience in this subject is embodied in *Pernicious Anaemia*, published in 1940, of which he was joint author. Gulland quickly became recognized, not merely as a keen laboratory worker, but also as a most accomplished physician. When I became his assistant physician nearly thirty years ago Gulland was a clinical teacher of extraordinary intellectual vigour and brilliance. The foundations of his conspicuous success in this field were laid in his early scientific training and research. Each day before his ward visit and teaching he made a personal study of the material being subjected to miscroscopical and biochemical analysis. He had a complete grasp of his subject, knew his cases thoroughly, yet treated them as patients, and had an innate gift, not merely of teaching, but of training his students, to each of whom he was a friend. In his clinical teaching the art, rather than the science, of medicine and the practical aspect of all therapeutic measures were constantly kept in the foreground, for he never forgot that nearly all his hearers would become medical practitioners. By reference to cases he had seen in former years he would frequently clarify a difficult point in diagnosis, and illustrate the value of a particular line of treatment.

It was in the diagnosis and treatment of acute disease that Gulland was pre-eminent. Thus it came about that he was *facile princeps* as consulting physician to the Forces in Malta in 1915, when the island, from Valetta to St. Paul's Bay, was a huge hospital, crowded with men evacuated from Gallipoli because they were suffering from acute dysentery, enteric fever, infective jaundice and other acute conditions. During that trying period his robust constitution, sanguine temperament and immense capacity for work stood him in good stead. His cheery smile and reassuring words could not fail to bring fresh hope to thousands of our sick soldiers. From Malta he was recalled amidst general acclamation to fill the Chair of Medicine and Clinical Medicine in Edinburgh, rendered vacant by the death of John Wyllie. During the thirteen years while Gulland held that office his lectures on the practice of medicine were characterized by a vigorous, lucid and helpful exposition of general principles. Throughout those years he was at the climax of his activity as teacher and consultant. In the latter capacity his professional skill deservedly commanded the confidence of his medical brethren and the public. His opinion was widely sought in all manner of difficult medical problems: in cases of anaemia of obscure origin his verdict was the final

court of appeal. He had a rare gift for quickly recognizing the essential feature of a difficult case and for not being misled by side issues. With him diagnosis was based upon solid foundations, prognosis upon sound judgment, treatment upon an unrivalled clinical experience.

After his retirement from the Chair his great powers of administration were given full rein as a member of the Board of Management of the Royal Infirmary: to his unerring judgment and tact we are indebted for the happy solution of maintaining an adequate and efficient honorary medical and surgical staff during the present emergency. For advice and guidance upon matters that are sometimes termed "medical etiquette" younger members of our profession would turn to Gulland, for he was the soul of honour, ever seeking and holding fast to that which is right and true. He was the very embodiment of Burns's "social, friendly and honest man." Everyone liked and admired him; those who knew him best loved him most. Unostentatious, of simple tastes and with a keen zest in all that is good in life, he was happy in his relation with men of all classes, in his work, his pleasures and, above all, in his home. A most genial host, he shone in any social gathering and had the delightful faculty of enlivening with songs of his own composition the informal meetings of Edinburgh medical dining clubs. We shall miss our revered Chief, colleague, and friend who has passed over to the other side, and in the days to come remember with pride and thankfulness his inspiring example.—W. J. R.

REDMOND ROCHE, M.R.C.S.

We regret to record the death, at the age of seventy-four, of Dr. Redmond Roche, who began his medical career in his native Ireland, but was for many years a well-known practitioner in the city of Westminster.

Redmond Roche was educated at Clongowes Wood College and what was then known as the Royal University of Ireland. He qualified in medicine in 1894, taking the English Conjoint diplomas and the licentiateship in midwifery (with special certificate in gynaecology), Rotunda Hospital, Dublin. Before crossing St. George's Channel he held a number of posts in Ireland, including that of demonstrator in anatomy at the Royal College of Surgeons and house appointments at Richmond Hospital, Whitworth Hospital, and Hardwick Fever Hospital in Dublin. He was for a time surgeon on R.M.S. *Vancouver* of the Dominion Line, and he also served as surgeon major in the 1st Cadet Battalion, King's Royal Rifles. During the early part of the last war he was an examiner of recruits in Whitehall and later medical officer in charge of the Scots Guards department, Wellington Barracks. In Westminster he practised at Eccleston Square, and among other public appointments he was medical officer to the Western Dispensary, Westminster. He joined the British Medical Association in 1897, and in 1925-6 he was chairman of the Westminster and Holborn Division. But his chief interest in medical affairs outside his own practice was as an active member and for many years president of the Society of Members of the Royal College of Surgeons. He took part, year after year, in moving the resolution, always carried and never acted upon, demanding the representation of members of the College Council. Unlike some of his colleagues in bygone years during these annual tilts at the council, Redmond Roche always spoke with the greatest suavity and reasonableness; nobody could better disguise a combative spirit in a gentle mien. He was a member of the Chelsea Clinical Society and contributed to its *Transactions*. He was also interested in medico-legal subjects, and on these and other matters his name appeared not infrequently in the correspondence columns of this *Journal*. Westminster will miss an excellent doctor and an engaging public figure.

MARY GORDON, L.R.C.P.&S.

We regret to announce the death on May 5 at Crowborough of Dr. Mary Louisa Gordon at the age of 79. She was a woman of great public spirit and independence of mind, and widely acquainted with penal methods and their results.

She studied at the London School of Medicine for Women, obtained the Scottish triple qualification in 1890, and after varied experience in social medicine and the treatment of alcoholism was appointed in 1908 H.M. Inspector of Female Prisons and assistant inspector of the State and Certified Inebriate Reformatories. For some months during the last war she served with the Serbian Transport Column in Macedonia. On retiring from official duties Dr. Mary Gordon summarized her experiences and gave earnest expression to the conclusions she had reached in a book published in 1922 under the title of *Penal Discipline*. Vigorous, racy, at times poetical in language, and throughout imbued with an active living sympathy for the derelict and diseased, it was the work of one who sees her fellow man or fellow woman even in the most abandoned criminal or "old lag." Those who had breathed the prison official atmosphere for any length of time and who knew anything of the author were not surprised to read that at her first round of inspections she unwittingly provided a sensation in several prisons, and also that, as an official, she feared she was never true to type. The book, however, was not a criticism of officialdom but of the prison system, and of its principle of penal discipline which was not made by the administrative body but by the citizens and voters of this country. Dr. Mary Gordon found nothing good in the prison system of her time, and implied, without explicitly saying so, that she looked upon the criminal as a sick person and not as a wrongdoer. The argument of her book was really for a changed public attitude towards the criminal, who should be treated scientifically but neither punished nor reproached. Long before *Penal Discipline* was published she had written a paper on the drug treatment of the inebriate, and she contributed the chapter on the inebriate derelict to the volume *Human Derelicts*.

THOMAS JASON WOOD, M.D., M.R.C.S.
Consulting Surgeon, Bradford Royal Infirmary

We regret to announce the death, which took place at Bradford on May 9 after an operation, of Dr. Thomas Jason Wood, a well-known consulting surgeon in the West Riding of Yorkshire.

He was born at Sevenoaks in 1866, and was educated at Bishop's Stortford School and University College Hospital. In 1890 he qualified M.R.C.S., L.R.C.P. and graduated M.B.Lond.; he took the M.D. degree in 1892. At U.C.H. he worked under the late Christopher Heath, and held the post of senior obstetrical assistant, afterwards acting as R.M.O. at Swansea Hospital. In 1895 he went to Bradford and entered into partnership with the late Dr. Mossop as a general practitioner, and in the same year he was appointed to the assistant staff of the Bradford Royal Infirmary, being promoted to the full staff in 1900. He retired from the full staff in 1923 and was appointed honorary consulting surgeon. During the 1914-18 war he acted as surgeon to the Bradford War Hospital (St. Luke's). He was a past-president of the Bradford Medico-Chirurgical Society and a past-chairman of the Bradford Division of the British Medical Association. During the Annual Meeting of the B.M.A. at Bradford in 1924 he was a vice-president of the Section of Surgery. He continued in practice as a consulting surgeon till ten years ago, when he retired. His hobbies were shooting, fishing, and golf, in all of which pursuits he showed considerable skill.

As a surgeon Dr. Jason Wood had a flair for diagnosis, especially abdominal diagnosis, and this was at a time when the ancillary diagnostic services were in their infancy. His anaesthetist says that he can hardly call to mind an occasion upon which Jason Wood opened an abdomen unnecessarily. As a man, to those who did not know him, he appeared to be austere and abrupt, but to his intimate friends or to anyone in real trouble he was kindness and consideration itself. He was honest and straightforward, but could not suffer fools gladly. In all that Jason Wood did, whether work or play, he was a true sportsman, and to the time of his death he took the greatest interest in the welfare and management of the Bradford Royal Infirmary. He is survived by his widow and two sons and three daughters.

Many friends (writes R. M.) will mourn the passing of a fine gentleman by the death of Dr. RICHARD KELLY, who for many years was one of Arbroath's most-sought-after and successful medical practitioners. Bournemouth, where he spent his later

years, has lost an ardent admirer and a picturesque personality. Two decades ago Dr. Kelly came south in retirement from a strenuous and exacting professional life, which had taken its toll of health and strength. He soon found that in the surroundings of his beloved Bournemouth health and vigour were restored and life began again to be joyous and worth-while. In his professional capacity Dr. Kelly had the gift of imparting confidence and reassurance while, at the same time, he was a great assessor of the verities behind his patients' condition He added to his methodical and painstaking nature a high endeavour to keep abreast, despite a busy life, with the varying and advancing research and technique of his profession He had been a member of the British Medical Association for fifty-two years and to the last was a faithful reader of the *British Medical Journal*.

One of the few nonagenarians in the medical profession has passed away with the death of DR. PHILIP LANCASHIRE BOOTH of Barrow-in-Furness. Dr. Booth was born in Manchester in 1849 and received his education at Owen's College. He qualified M.R.C.S. in 1873, and in the following year was appointed house-surgeon at North Lonsdale Hospital, Barrow, then a very unpretentious wooden building, and now a modern hospital of 154 beds. Very soon he bought a practice and settled down in that town, which was then rapidly developing as a mining and industrial centre, and there and on the adjacent island of Walney he practised for not far short of seventy years. Dr. Booth was a member of the British Medical Association from 1877 onwards, and was chairman of the Furness Division in 1932-3. But he had no ambition to be other than a local medical practitioner, serving the North Lancashire folk whom he knew so well. He was honorary surgeon to the North Lonsdale Hospital down to his death. His only outside interests were in Freemasonry, in which he attained high Provincial rank, and choral societies and church choirs, in which he took an active part from boyhood right into old age. It is possible that he was the oldest doctor in practice in England.

DR. CHRISTABEL LILIE MARGARET GWYNNE-JONES (née Charlesworth) was killed by enemy action in one of the recent air raids on Plymouth. She was the wife of Surgeon Commander T. Gwynne-Jones, R.N., who seems to have been on duty in Devonport Dockyard at the time and so escaped. Her maid, Dorothy Remick, was killed at the same time. Dr. Christabel Gwynne-Jones was educated at Glasgow University, where she graduated as M B. and Ch.B. in 1921, and at King's College, London, also taking the M.R.C.S. and L.R.C.P. diplomas in the same year.

Universities and Colleges

UNIVERSITY OF OXFORD

Miss Ida Mann, D.Sc., M.B., F.R.C.S., has been appointed to the Margaret Ogilvie Readership in Ophthalmology from October 1.

UNIVERSITY OF CAMBRIDGE

At a Congregation held on May 12 the following medical degrees were conferred:

M.B., B.CHIR.—By Proxy: D. Laing, E. J. C. Kendall.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh, held on May 14, with Dr. H. M. Traquair, President, in the chair, the following, having passed the requisite examinations, were admitted Fellows:

G. J. Cleland, G. J. A. Kirkpatrick, F. B. Korkis, J. C. Milne, D. M. Nundy, Marion A. Pearson, O. McC. Spence, W. J. Watt.

The Henry Arthur Dalziel Ferns Bursary was, after a competitive examination in organic chemistry in its application to medicine, awarded to Mr. N. Meleca.

The Ivison Macadam Memorial Prize was, after a competitive examination in inorganic and organic chemistry in its application to medicine, awarded to Miss Mary McDonald.

The Bathgate Memorial Prize was, after a competitive examination in materia medica and therapeutics, awarded to Mr. E. D. Cameron.

Medical Notes in Parliament

Medical Man-power and Alien Doctors

The question of the Government's treatment of alien doctors in relation to medical man-power was raised by Sir HENRY MORRIS-JONES in the House of Commons on May 13. He contended that there had been a good deal of chaos and muddle in dealing with the matter. Last January there were 1,400 alien doctors in this country, and roughly only 100 had found employment. The fault lay with the multiplicity of Government and Service Departments and Refugee Committees. The Central Medical War Committee had an inadequate staff to deal with the matter, and he was told that there was only one official to deal with this question at the moment. There was also serious delay at the Aliens Department of the Home Office, which was causing a hold-up. This Department was the bottle-neck. It would take three years to absorb these alien doctors at the present rate. Some hospitals had appointed alien doctors, as they could not get other medical assistance, and sometimes it had taken two months to get sanction from the Home Office to do this. It was now announced that we were to take 1,000 American doctors into the R.A.M.C. While he believed in Anglo-American co-operation, we should not shout from the housetops about asking them to come here and then do an injustice to those who had been here for so long. We should not discourage these American doctors by putting them into the R.A.M.C. to clean instruments for a few hours a day, but should see that their skill was made use of in the best possible way. Our medical man-power was very badly distributed at present, and in rural areas it was often impossible to find a medical man to attend even a confinement case. The R.A.M.C. seemed, owing to the peculiar character of the war, to have an avaricious appetite for medical personnel, although there was not much work for them to do. The Central Medical War Committee had done very valuable work in the war, but the whole question had now got beyond them. The Minister of Health ought to take the matter into his own hands and appoint committees in each county or each county borough of over 250,000 population. The committee should comprise a representative of the British Medical Association, a responsible public man from the county, and representatives of the trade unions and employers.

Sir FRANCIS FREMANTLE pointed out that the Central Medical War Committee was set up by agreement with independent bodies like the Royal Colleges of Physicians and Surgeons, and direct representation was given to those bodies. It was probably the most representative body of the medical profession that could be got. It was obviously a great deal better for a question like this to be dealt with by the profession as a whole than to be taken over by a Government Department. The Central Medical War Committee was as conscious of the difficulty of the alien doctors as anyone else, and was as keen as Sir Henry Morris-Jones to use these people. There was no lack of good will—certainly not consciously. With regard to the suggestion that the Ministry of Health should take over the whole of the work and appoint local committees, he pointed out that Local Medical War Committees already existed in each area, which gave up their time to the very unpleasant work of deciding among their own colleagues whom they would root out from their practice and compel to serve. Continuing, he said it was not so easy as it might seem to employ alien doctors. Most of them could not talk English or, if they did, it was broken English. It was very difficult for them to understand the ways of the British medical profession and still more difficult to understand British patients in order to prescribe for them. It was difficult for them to use the organization to which they were to be appointed and the conditions and circumstances in which they had to recommend the application of their advice to their patients.

Prof. A. V. HILL said that we had been unexpectedly fortunate so far during the war in the matter of our public health, but we must not assume that our present good fortune would necessarily continue. Britain's medical resources were taxed to the utmost. In ordinary times we might have enough doctors as we were organized—that was, for dealing with disease only; but we should not have more than from one-third to two-thirds of the doctors wanted if health were to be regarded

as the essential thing and not the treatment of the disease only. In wartime, even more than in peace, we had to think ahead We knew that 3,000 deaths from diphtheria and 60,000 cases annually could be abolished if only we could think ahead, if the Government and the people were not so complacent, and doctors were available to carry out the necessary immunization. If we were to avoid disease then far more doctors were required. For this reason we could only welcome with gratitude the promise of the United States to send 1,000 doctors to help us. It was appalling that we should have 1,300 doctors from Europe unemployed of the 1,400 available. The story that our people would not accept these doctors and that the hospitals did not want them seemed to him to be nonsense. Many Czech doctors spoke English well and had great professional knowledge and skill. The people who raised these objections were often disguising their own prejudices by referring them to the common people. Actually, little objection to the employment of alien doctors was openly voiced by the medical profession and practically no objection by our people.

GOVERNMENT REPLY

Miss HORSBRUGH, replying to the debate, said that in the employment of alien doctors they had to make certain that the doctor had skill and that his training was what he professed it to be. If he was to go into the hospitals it was natural that one must check these things. We had also to check that he was loyal to this country. The arrangement by which Allied doctors would be welcome to serve in our hospitals had been working for about four months. She did not say that the number already employed was satisfactory, because she thought the machine had got into action too slowly. She believed that the number of alien doctors was 1,350 and that now 200 or 250 were being employed. Fifty-nine doctors obtained employment at a hospital first and then their credentials were checked. The names of 333 were sent in to the Security Department and arrangements were made for 224 of that number. Then 126 were registered with the General Medical Council and she thought they were in employment, while 98 remained in the pool that had now been created. Their bona-fides had been examined and they were awaiting employment. The main scheme had been slow, but we had increased the pace, and the numbers now coming through from the Home Office Department were at the rate of about 100 a week. A great many were specialists, and it was not always possible to employ them in their own specialty. Doctors were wanted most for junior positions in a hospital, but some of them would not be suitable for such posts. Others, by reason of part-time work and studies, could not give their whole time. The Ministry was very anxious that they should be employed.

She welcomed the 1,000 doctors coming from America. While the Army was in this country and troops were stationed in a particular town and had no R.A.M.C. doctors they could be attended by the local practitioners. But at any moment the troops might leave the district, and the personnel of the R.A.M.C. must be sufficient to provide for the troops when they had to move. It was not necessarily the case that the majority of the alien doctors could not speak English. A great many of them, however, could not, and one of the difficulties might be that of language if the foreign doctors were used as we hoped to use the American ones. Those who did not speak English, as well as others, found it far easier to work in the hospitals with doctors who could assist them. The trouble in dealing with alien doctors was not complacency, but perhaps a machine that had worked too slowly. The checking up had been slow, but it was a great deal better to be slow than to make a mistake as to a doctor's skill or his loyalty to the country. She hoped that the numbers of alien doctors to be employed would be 100 a week and perhaps increased to 150.

Medical Certification

On May 15 Mr. CULVERWELL asserted that absenteeism and the transfer of labour were facilitated by the ease with which medical certificates could be obtained. He asked Mr. Bevin to ensure that doctors granted such certificates only for genuine cases of sickness or physical disability. Mr. BEVIN said he received representations on the ease with which medical certificates were alleged to be obtainable in certain cases. He proposed to consult Mr. Ernest Brown on the matter. In his Department certificates given by medical practitioners in their private capacity were not necessarily accepted as conclusive. An independent medical examination was required when this seemed necessary. Mr. CULVERWELL asked Mr. Bevin to secure the co-operation of the British Medical Association in checking "this abuse." He also asked him to ensure wide publicity for his reply. Mr. SHINWELL asked Mr. Bevin to go into the matter carefully in view of the slur cast on the workers.

Mr. BEVIN replied that he was going into the matter. Under the Essential Work Order it was possible to test the facts. He was satisfied there was at least *prima facie* evidence that, in giving panel certificates, there had not been the care which ought to have been exercised. The genuineness of any medical certificate could be examined by the Ministry of Labour. He reminded the House that constant building up of more forms of medical boards involved a great deal of organization for what might be a comparatively few cases. In his view the medical profession, "like every other trade union," ought to accept their responsibilities. Sir FRANCIS FREMANTLE said the medical profession was not a trade union and had never been.

Horseflesh in Popular Foods

Mr. ERNEST BROWN said on May 13 that to some extent there was an admixture of horseflesh with beef in various articles of popular consumption. Apart from the general provisions of the Food and Drugs Act, 1938, for the protection of purchasers, including those relating to labelling, the Act contained detailed provisions relating to the sale of horseflesh and articles of food containing it, the administration of which was a matter for the local authorities.

Differential "Iron Rations."—Major LLOYD GEORGE, replying to Miss Rathbone on May 7, said he and his advisers had not worked out, in terms of the available commodities, the minimum "iron rations" necessary to sustain in full health and efficiency heavy workers, adults other than heavy workers, children, and infants, respectively. It was the considered policy to allow the maximum possible ration to all rather than differential rations to particular categories. He was satisfied that the diet that could be obtained under existing conditions was adequate. Difficulties of distribution would be insuperable if the rationing system were calculated to ensure that everyone could secure the approximate equivalent of his appropriate iron ration and no more. He added that plenty of information on iron rations was available in the Ministry of Food.

The Services

ARMY AWARD

The D.S.O. has been awarded to Lieut. (Temporary Captain) Thomas Victor Somerville, R.A.M.C., and he has also been mentioned in dispatches for distinguished services in the Middle East.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

The death is announced of Surgeon Lieut. JOHN MORTIMER WATSON, R.N.V.R., the younger son of Dr. and Mrs. H. A. Watson of Worcester, at the age of 27. He received his medical education at King's College Hospital and qualified M.R.C.S., L.R.C.P. in 1938. He had held the post of senior resident medical officer at the Royal Buckinghamshire Hospital, Aylesbury, and was house-surgeon at King's College Hospital.

Surgeon Lieut. GEORGE THEODORE ROBERTSON WATT, R.N.V.R., was killed by enemy action when his ship, H.M.S. *Wryneck*, was sunk in the Aegean Sea during the recent evacuation from Greece. He was the eldest son of Dr. Theodore Watt and was educated at Aberdeen Grammar School and at the University of Aberdeen, where he graduated M.B., Ch.B. in 1936. After qualifying he held resident posts at Aberdeen Royal Infirmary, Mount Vernon Hospital, Northwood, Aberdeen Maternity Hospital, and at the Jessop Hospital for Women, Sheffield. He joined the R.N.V.R. in June, 1940, when he was posted to the destroyer *Wryneck*. He had been a member of the British Medical Association since graduation.

DEATHS IN THE SERVICES

Colonel WILLIAM SOUTHWICK WILLMORE, I.M.S. (ret.), died suddenly at Churt, Surrey, on May 3, aged 68. He was born on August 7, 1872, was educated at Birmingham and at St. Thomas's Hospital, and took the M.R.C.S., L.R.C.P. in 1895. Subsequently he took the D.T.M. and H. in 1907, the M.R.C.P. in 1908, and the M.D. of Durham in 1913. After qualifying he held several house appointments at Queen's Hospital, Birmingham. He entered the I.M.S. as lieutenant in 1899, attained

the rank of full colonel in 1927, and retired in 1929. Most of his service was spent in the United Provinces in civil employ, which he entered in 1903. In 1914 he was civil surgeon of Agra and principal of Agra Medical School. In October, 1914, he reverted to military duty and served with the Army until January, 1920. He was appointed professor in King George's Medical College, Lucknow, in 1922, and in 1923 civil surgeon of Cawnpore. On promotion to administrative rank in 1927 he became Inspector-General of Civil Hospitals in Bihar and Orissa, where he remained until he retired, after which he settled at Felsted in Essex, and was consulting physician to Felsted School. He served in the China War of 1900, when he took part in the relief of Peking and in the actions at Peh-tsang and Yangtsun, receiving the medal with a clasp. He had been a member of the British Medical Association for forty years and was chairman of the Mid-Essex Division in 1937.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The incidence of the common infectious diseases in England and Wales, with the exception of whooping-cough, showed only slight variations from that of the previous week. In Scotland the notifications of whooping-cough and dysentery have increased 100%, and a considerable increase has occurred in the incidence of cerebrospinal fever and typhoid fever. The number of cases of measles has declined by 68 for the whole country, but the returns for the individual counties showed some fluctuations: from Durham, Kent, and London over a hundred more cases were recorded than in the preceding week. The incidence of scarlet fever decreased by 35 cases during the week under review and the notifications were the lowest since last summer. A slight increase, 35, in the number of cases of diphtheria was reported in England and Wales. With the small decrease, 9, in the returns for Scotland the incidence of this disease reached the lowest level of recent months. The relatively large increase in enteric fever in Scotland, from 45 to 75 cases, was due to an outbreak of paratyphoid fever in Dundee, where 55 cases were reported during the week.

Whooping-cough

A general rise in the incidence of this disease is recorded for the week under review. In England and Wales 4,187 fresh cases were notified, an increase of 619, and in Scotland 549 cases, an increase of 330. In England and Wales the increase was distributed over the whole country, the largest rises being in Surrey, Lancashire, and York, West Riding, where the totals were respectively 79, 70, and 69 in excess of those of the preceding week. Whooping-cough is not generally notifiable in Scotland, and the returns are dominated by the experience of Glasgow, which contributed four-fifths of the total cases notified in the country.

Dysentery

For the third consecutive week the number of notifications of dysentery in England and Wales has shown a fall. Only 8 further cases were recorded in the Hertfordshire outbreak, but another rise occurred in Whiston R.D., Lancs, where 15 fresh cases were notified. In Scotland the number of cases of dysentery was doubled, 63 compared with 32 in the previous week: 24 of the cases were reported from the county of Argyll, and the cities of Aberdeen and Glasgow contributed 11 and 8 cases respectively.

Cerebrospinal Fever

There was a slight decrease, 17, in the notifications of this disease in England and Wales during the week. The general trend of this disease during the past seven weeks has been to oscillate round a constant level. The rate of decline in the ten weeks following the maximum has been less than that experienced in the epidemic of last year. Isolated cases of cerebrospinal fever were reported from all over the country, but half of the total cases were from only five counties—Lancaster 34, London 22, Warwickshire 18, Yorks W.R. 39, and Glamorganshire 20. The returns for Scotland showed an increase for the second consecutive week and the total reached the level recorded in March. The largest outbreaks were those of Glasgow, 32 cases, and Edinburgh, 11 cases.

No. 17

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended April 26.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 15 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 11 principal towns in Northern Ireland.

A dash — denotes no cases: a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	1941 (b)	1941 (c)	1941 (d)	1941 (e)	1940 (Corresponding Weeks) (a)	1940 (Corresponding Weeks) (b)	1940 (Corresponding Weeks) (c)	1940 (Corresponding Weeks) (d)	1940 (Corresponding Weeks) (e)

Stillbirths	229	13	30			256	31	41		
Rate per 1,000 total births (including stillborn)			32					41		

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Medical News

Those who are interested in the Near East and in medical international work are invited to the forty-second annual meeting of the Lebanon Hospital for Mental Diseases, Syria, on Thursday, June 5, at 4.15 p.m., in the garden lounge of the Westway Hotel, Endsleigh Street, London, W.C. The speakers include Mrs. Somerville Smith, representative in London of the British-American Ambulance Corps, and M. Mathieu, formerly interpreter at the League of Nations, who will speak on the situation in Syria.

The seventy-fifth anniversary of the founding of New York City Department of Health was observed on March 5, when the speakers were Mayor La Guardia, Drs. John L. Rice, health commissioner, Haren Emerson, and Jones Alexander Miller. Seventy-five years ago the general death rate was 35 per 1,000 of population and the infant mortality 245 per 1,000 live births. Last year the death rate was 10.3 and the infant mortality 35.

The sixty-fourth annual meeting of the American Dermatological Association was held at New Orleans from April 7 to 10. The proceedings included a clinical session at the National Leprosarium at Carville, Louisiana, which gave an exceptional opportunity for the study of leprosy. After the presidential address by Dr. William H. Guy twenty-two miscellaneous papers on clinical and pathological aspects of skin diseases and syphilis were read and discussed on the first, second, and third days. The final scientific session was given up to a symposium on superficial fungous infections. A report on the effects of copper sulphate iontophoresis in a series of cases of fungous infection of the skin showed the failure of such treatment to act as a fungicide. A report on the preparation and clinical application of undenatured trichophytin indicated that this is a satisfactory antigen for diagnostic and therapeutic purposes. Another report suggested that there were two separate factors in trichophytin: one a skin reactivity factor, and the other a desensitizing or therapeutic principle. There was also a report of an analysis of fungi found on the feet and in shoes in dermatophytosis, and a statistical analysis of eighty-eight replies to a questionary on familial and conjugal transmission of two common forms of fungous infections of the glabrous skin.

The Minister of Food has made an Order, to come into force on June 2, prohibiting, except under licence, the manufacture or sale of vitamin C. The Order does not apply to the manufacture or sale of vitamin C for medicinal, pharmaceutical, or scientific purposes. Applications for licences should be made to the Ministry of Food, St. John's College, Oxford.

The names of Dr. Richard Arden Jones, Emergency Medical Service, Newmarket, and Dr. William Thomas Garthorpe Boul, medical officer of health, Civil Defence Services, Thurrock, have been brought to notice for brave conduct in civil defence.

BATTERIES FOR THE DEAF

The Board of Trade announces that arrangements have been completed for the manufacture of an adequate supply of high-tension batteries to meet the needs of deaf persons who use hearing aids. Owing to Service requirements of batteries, it has, however, been found necessary to curtail considerably the number of different types of these batteries, and manufacture will be restricted to an agreed range of standard types.

The new types have been designed to cover the requirements of all existing United Kingdom makes of hearing aids which employ high-tension batteries, but it may be found that some instruments will need minor modification in order to accommodate them. In general, it will be found that the new batteries are rather larger than those formerly in use, but every endeavour has been made to ensure that alterations to instruments, where necessary, shall be of a minor character and confined to the battery casing only. No modifications will be required in the mechanism of any instrument. Users of hearing aids are advised to communicate with the manufacturers of their apparatus, who will inform them of the most appropriate new types of battery and of any modifications to their sets which may be necessary.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London;* SECRETARY, *Medisecra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Income Tax

Annuity Policy

"FRANCIS" has "for a number of years" paid £86 for an annuity payable at sixty-one. Is he entitled to any allowance?

* * The answer is No, unless the policy (*a*) was taken out on or before June 22, 1916, or (*b*) was "made in connexion with any superannuation or bona-fide pension scheme for the benefit of the employees of any employer or of persons engaged in any particular trade, profession, vocation or business."

Service in Forces Abroad: Wife's Income

"PERPLEXED" has been abroad on naval service and is regarded as "non-resident" for the years 1938-9 and 1939-40. His wife was also abroad, and her income, though not liable to British income tax, has to be brought into the computation of "Perplexed's" proportionate liability on his naval pay. Is this correct?

* * Apparently it is. It may not follow that "Perplexed" is worse off because he is regarded as a non-resident if (as may be the case) his own residential circumstances might be taken into account in deciding whether his wife is to be regarded as a non-resident for the years in question. Tax on her income would far outweigh the present loss. In the circumstances "Perplexed" is advised to await the result of his plea for reconsideration on equitable grounds.

Motor Car—Replacement Allowance

"N. F." bought a car in 1934 for £505 and sold it in 1939 for £47, buying a small car for £174. No depreciation allowance has been claimed. The inspector of taxes now proposes to allow only £174 − £47 = £127—i.e., the actual out-of-pocket expense. Is this correct?

* * Yes. Depreciation should be claimed each year, because the lump sum claim cannot exceed the net cost of the replacement. We advise "N.F." to lodge a claim to reopen the past six years' assessments on the ground of an error or mistake in his past returns—i.e., the omission to claim depreciation allowance. But if the omission was deliberate the claim is not a good one.

LETTERS, NOTES, ETC.

Nitrous Oxide for Dental Anaesthesia

THE BRITISH OXYGEN COMPANY LIMITED write: We would refer you to Mr. B. Richardson Billings's letter (April 19, p. 608), in which he states that he has been "driven to the conclusion that the war product differs considerably in its effects (and possibly in its method of production) from pre-war nitrous oxide." As the manufacturers of practically the total consumption of nitrous oxide in the country we should like to state that there is no difference whatever in the quality as compared with pre-war days. Certain manufacturers of quality products may, in wartime, have difficulty in securing a regular supply of first-grade raw materials and are therefore unable to maintain their high standards, but in the case of the manufacture of nitrous oxide no such difficulties have arisen, and we make the definite statement that our high standard of purity is comparable with pre-war production. When practitioners are not obtaining the best results we find on most occasions that a minor adjustment to their medical apparatus remedies matters.

Corrigendum

Dr. JAMES REID wishes to draw attention to an error in his article on "Prothrombin Deficiency in Disease of the Liver and Bile Passages" (*Journal*, April 19). On page 580, column 1, line 5, "M/10 calcium chloride solution" should have read "M/40 calcium chloride solution."

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 24 1941

MEDICAL WAR RELIEF FUND

SIXTEENTH LIST

Previously acknowledged, £22,965 11s. 11d. and £100 3½% Conversion Stock

Individual Subscriptions

£21.—Dr. E. S. Orme, Wendover.
£10 10s.—Sir Comyns Berkeley, London; Dr. P. Lund Pollard, Halifax.
£7 7s.—Dr. J. A. Small, Norwich.
£6 6s.—Per Dr. F. S. Airey, Leicester.
£5 5s.—Dr. R. H. Balfour Barrow, Winchester (2nd donation); Lt.-Col. G. T. Burke, I.M.S. (Ret.), Bexhill-on-Sea; Dr. E. C. Dawson, Derby (3rd donation); Mr. H. Dodd, London; Dr. T. Fraser, Bishop Auckland; Dr. F. C. C. Jasper, Winchester; Dr. T. B. Jobson, Guildford; Mr. A. Leach Bath; Dr. H. Malleson, Winchester; Mr. B. H. Pidcock, Winchester; Dr. G. Marsden Roberts, Winchester; Dr. R. I. Roberts, Winchester; Dr. E. R. Tivy, Walthamstow.
£5.—Dr. G. F. Barham, Gorran Haven; Dr. J. C. M. Gran, Tunbridge Wells (2nd donation); Dr. S. Hunt, Spridlington (2nd donation); Dr. G. M. Kendall, Epsom; Lt.-Col. R. M. Lee, I.M.S. (Ret.), Bombay; Dr. Eleanor O'Donovan, Topsham.
£4 6s.—Miss Margaret Moore White, London (4th donation).
£3 3s.—Col. F. P. Mackie, Bristol.
£3.—Lt.-Col. G. Hebart, R.A.M.C.
£2 10s.—Dr. A. E. P. Parker, Middlesbrough.
£2 2s.—Dr. H. F. Blood Beeper; Dr. J. W. Clare, Shaftesbury; Dr. G. Day, Norwich; Dr. C. Tilbury Fox, Ashford, Kent; Dr. W. H. Lindsay, Lonacre; Dr. R. A. Murphy, Chingford; Dr. A. M. Pertelus, Essington; Dr. H. J. Powers, Brighton; Dr. E. S. Robinson, Stourport; Dr. S. Robinson London; Dr. W. L. Smith, Glasgow; Dr. T. Blandford Watson, West Hartlepool.
£2.—Dr. Irene F. Callander, India.
£1 1s.—Dr. A. Court, Chesterfield; Dr. A. W. Davison, Manchester; Dr. A. Greer, London; Dr. J. L. Hessrani, Colchester; Surg. Lt.-Cdr. D. B. Jack, R.N.; Lt. G. B. Macmeikan, R.A.M.C.; Dr. Anne Mitchell, Craigavon; Dr. L. Perrier, Chipley; Dr. C. B. Slater, Worthing; Dr. Basil L. Steele, London, Dr. Russell V. Steele, London.
12s. 6d.—Dr. J. Green, London.
10s. 6d.—Dr. T. Benton Evans, Prestatyn.
£126 10s.—St. Clements, Winchester.
£112 16s.—Practitioners in Lincoln Division area—per Mr. Bagot Walters (amount already sent, £93 15s. 6d.): Dr. F. W. Shepeg, £2 2s.; Dr. J. L. Taylor, £2 2s.; Dr. A. H. Hogg, £2 2s.; Dr. M. Staffing of Hospitals

SIR,—When Dr. Terry Pybus put forward his now famous scheme for a State Medical Service (*Supplement*, March 15, p. 29) he started a train of medical cerebration of an unusual order. Numbers of us, content to earn our living in the bad old way, have suddenly discovered to our consternation that there are some members of the profession wanting a form of medical "new order" after this war is over. We have but to look around at the fruits of the National Health Insurance Acts and other premature offspring of the Public Health Services to make us dread this further infliction on our professional life. If our would-be reformers, including Dr. Pybus, are determined to make a change, then I suggest that they start and evolve a new system of staffing our hospitals. The present system of restricted staffs is archaic, unfair, and wasteful of professional effort, and has given rise to nepotism and medical cliques. This system is even now undermining our medical war effort through its Local Medical War Committees forming a sort of local "Gestapo" from which there is no escape. The only way for the rank and file to break loose

from these organized professional rings, which centre around the staffs of our local hospitals, is to throw open all general hospitals (excluding the large teaching ones) to every practitioner on the *Medical Register*. This is done in most of the more advanced and progressive hospitals of Western Canada and other States of the Commonwealth.

I venture the opinion that the restricted staffing of local hospitals, particularly in the Provinces, has done more to disorganize and break up the profession into antagonizing groups than any other single factor. If we must have competition, then let it be open, fair, and free to all ; let every dog have a bite.—I am, etc.,

Bournemouth, May 12. VINCENT NORMAN.

State Medical Service

SIR,—Many of your correspondents evidently fear that the introduction of a State Medical Service would result in inadequate payment and "sweating" of the medical men forming the Service. In 1912, nearly thirty years ago, the panel system was introduced and a scale of remuneration laid down, a scale even at that time considered unfairly low. Nevertheless, despite all the efforts of the B.M.A., this scale has never been improved upon, the enormous increase that has occurred in the cost of living and the largely increased scale of wages of the working classes notwithstanding. In the same period the emoluments of the Colonial Medical Service—essentially a State Medical Service—have been increased by 50% as a result of representations by the Association to the Colonial Office. The State Medical Service, an organized body with a common interest, is successful in obtaining adequate remuneration, while panel practitioners, lacking that unity, fail in a similar effort. *Verb. sap.*

The excellently equipped research institutes, laboratories, hospitals and medical schools scattered throughout the Colonial Empire are sufficient answer to the fear that State hospitals and clinics must inevitably be ill equipped. Publications such as the *Journal of the Royal Society of Tropical Medicine and Hygiene* and the *East African* and *Malayan Medical Journals* are sufficient index of the professional ability of the "bureaucratic Civil Servants" who constitute the State Medical Service of the Colonies.—I am, etc.,

B. SPEARMAN,
Colonial Medical Service (ret.).

Gillingham, Dorset, May 12.

DOMICILIARY ATTENDANCE ON EVACUATED ADULTS AND ACCOMPANIED CHILDREN

The Ministry of Health has communicated with its Regional Officers on the subject of domiciliary attention for evacuated adults and accompanied children. Some time ago the Ministry advised county councils and county borough councils to extend the district medical service where necessary to provide attention for uninsured evacuated adults unable to pay for treatment and accompanied children. The Ministry has now advised its Regional Officers on the various methods of extending this service, and of an agreement reached with the British Medical Association on remuneration.

One method of extending the service is by appointing new medical officers or by increasing the salaries of existing district medical officers. In these cases the salary depends on the work to be done and must be related to the facts of the individual case. The Ministry's communication relates to proposals to remunerate additional or existing district medical officers otherwise than by salary, or to introduce an open-choice scheme for evacuated persons where such a scheme is not already in operation. In these circumstances the basis agreed between the Ministry and the Association is that of a quarterly payment per patient treated, the method generally in operation in existing open-choice schemes.

The Ministry's Regional Officers have been asked in these circumstances to approve only those proposals which are in conformity with the agreed terms :

(a) Payment should be by a fee per patient treated.

(b) The fee should cover treatment for the period of three months following the first visit or attendance, and should include travelling and the supply of medicine and medical and surgical appliances which are provided by way of medical benefit under National Health Insurance.

(c) The fee should be not less than 7s. 6d. and not more than 10s. 6d. The margin is designed to allow for different types of area—that is, in an urban area the fee would be nearer 7s. 6d.; in a rural nearer 10s. 6d. owing to extra travelling.

(d) Where an illness is so prolonged that it involves *continuous* attention over a period of more than three months the amount of the fee paid should be *four times* the quarter's fee, whether the illness continues for the whole year or not.

Medical Services of H.M. Forces Appointments

ROYAL NAVY

Acting Surgeon Lieut.-Commander F. H. Ward to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Acting Surgeon Lieut.-Commander A. I. L. Maitland to be Surgeon Lieutenant-Commander.

To be Temporary Surgeon Lieutenants: J. E. Tillotson, F. Whitwell, R. Rowlandson, S. J. Allen, G. R. Nicks, T. T. Schofield, G. J. Potts, F. H. D. Hutter, N. G. Lindsay, J. N. G. Way, A. C. Mackay, A. J. E. Barlow.

Probationary Temporary Surgeon Lieutenants R. E. Prichard, C. A. Milner, W. G. L. Hall, C. J. Rooke, D. J. MacMillan, A. H. Murray, A. T. Marshall, W. D. Thompson, K. B. Scott, A. Whitewright, W. Phillips, J. L. Temple, A. P. Walker, P. B. Woodyatt, T. P. Griffin, R. F. Lavelle, A. H. Zuckerman, M. C. Wood, C. M. T. Adamson, M. Glick, E. A. Spouse, H. M. Tucker, P. H. Tooley, R. Scott, J. D. M. Barton, R. G. Harcourt, H. G. B. Woollatt, J. K. Thomson, P. A. Walshaw, J. P. G. Rogerson, M. M. Walker, J. Taylor, E. M. Webster, R. Ransome-Wallis, D. H. Davies, J. C. Simson, C. S. Sandeman, J. J. Walker, and J. D. Randall to be Temporary Surgeon Lieutenants.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel E. F. W. Grellier, having attained the age for retirement, has retired, and remains employed.

Major (temporary Lieut.-Colonel) T. Young to be Lieutenant-Colonel.

Captain (temporary Major) C. P. Stevens, a Short Service Officer, has been appointed to a permanent commission.

Postgraduate News

The Fellowship of Medicine announces the following courses for (Final) F.R.C.S. candidates: (1) Clinical course, Wednesdays, 2 p.m., July 2 to 23; (2) Revision course, daily, 10 a.m. to 1 p.m., July 7 to August 1; (3) Practical operative surgery course, Mondays, Thursdays, and Fridays, 2 p.m. to 4 p.m., July 7 to August 1.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.1.—Brompton Hospital, S.W.—Mon. and Thurs., 5 p.m., M.R.C.P. Course in Chest Diseases. West End Hospital for Nervous Diseases.—Tues. and Fri., 5.30 p.m., M.R.C.P. Course in Neurology.

Road, W.—Mon., Course ences. Daily, 10 a.m. to

Royal Infirmary, rachcobronchoscopy

DIARY OF SOCIETIES AND LECTURES

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.—Tues., 2.30 p.m. General meeting. Discussion: Venereal Buboes. To be opened by Dr. H. M. Hanschell.

VACANCIES

EXAMINING following vacant appointments are announced: Woodford (Northamptonshire); Crawley (S Chief Inspector of Factories, Queen Anne's Cha W.1, by June 3.

APPOINTMENTS

EXAMINING FACTORY SURGEONS.—W. M. Kirkby, M.R.C.S., L.R.C.P., for the Porthcawl District (Glamorganshire); W. Parry-Jones, M.R.C.S., L.R.C.P., for the Llangefni District (Anglesey).

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

COLEMAN.—On Sunday, May 11, 1941, at Sandford, Llandudno, to Mildred, wife of A. H. Coleman, F.R.C.S., a son (both doing well).

DEATH

THOMSON.—On April 7, 1941, Dr. Bailey Thomson, at Balbegno, Carlton Road, Nottingham.

positive reactions—31 in sixteen hours and 16 in forty hours. Six grew poorly, but on repeating the tests they all grew well and gave strongly positive reactions in forty hours, one requiring a more concentrated inoculum. A further 5 reacted feebly, although they grew well; on retesting with another serum 3 of these reacted strongly but 2 remained weak reactors. In routine practice the colony test was applied to 43 plates directly seeded from wound swabs or dust. Of these, 20 reacted strongly in sixteen hours and 15 in forty hours. Nine grew poorly, but growth was sufficient to give a definite reaction in all but two of them. These two were strongly positive when retested with a drop of broth culture as inoculum.

Incubation and Centrifugation.—Most strains are positive in sixteen or forty hours, and a few require sixty-four hours' incubation; but no change has been observed after sixty-four hours. Strong reactions are obvious without spinning, but the detection of weak reactions and the confirmation of negatives are impossible without a comparison of centrifuged tests and control tubes. It should be noted (see above) that a floating mass of floccules may be changed to a sedimenting precipitate with prolonged incubation of the test mixture.

Reactions with Cl. welchii

Fifty-eight strains have been tested: 3 stock cultures (one each of Types A, B, and C), and 55 recently isolated cultures—51 from wounds in 39 persons and 4 from sand and air. Nine of the wound strains were kindly sent by Dr. E. T. C. Spooner. Of the 46 strains isolated in this laboratory 45 were identified as *Cl. welchii* on morphological, cultural, and biochemical characteristics. Many were tested in guinea-pigs and mice, with antitoxin controls. One strain, even after repeated purification, slowly digested and blackened meat broth persistently, and fermented salicin but not sucrose; it gave typical disease in the guinea-pig and killed a normal but not an antitoxin-treated mouse. Of these 58 strains 56 (96%) gave strong reactions when the growth was good. Two grew well, but reacted feebly with serum from young adults, although they reacted strongly with a senile serum. One of these—beta-haemolytic on horse-blood agar, and pathogenic for guinea-pigs but not mice—reacted strongly with yolk saline. The other was non-haemolytic and non-pathogenic, and reacted feebly with yolk saline. These reactions, though feeble, were definite and were inhibited by antitoxin, but in view of the "specific" reaction by other clostridia cannot be considered as exclusively characteristic of *Cl. welchii*.

Reactions with Other Bacteria

Anaerobes.—Tests have been carried out on 174 cultures of anaerobes other than *Cl. welchii*. These included 67 of the *Cl. sporogenes* type, 6 *Cl. septicum*, 10 *Cl. tetani* of different serological types, 2 *Cl. multifermentans tenalbus*, 1 each of *Cl. botulinum*, *Cl. sphenoides*, *Cl. histolyticum*, *Cl. tetanomorphum*, *Cl. oedematiens*, *Cl. bifermentans*, N.C.T.C. 2914, *Cl. sordellii*, N.C.T.C. 2919, *Cl. parasporogenes*, *Cl. centrosporogenes*, N.C.T.C. 1341, *Cl. fallax*, and *Cl. hastiforme*, 66 not yet fully identified proteolytic anaerobes, 11 not yet fully identified saccharolytic anaerobes which by reason of spore position, colony form, or sugar reactions were known not to be *Cl. welchii*, and an anaerobic coccus. Of these, 165 gave no Nagler reaction, although some gave a slight turbidity in both test and control tubes. The remaining 9 cultures were feebly but definitely positive, the reaction being inhibited by *welchii* antitoxin, and appearing both in yolk saline and in serum. On human serum-Fildes's-agar plates they produced a well-defined opacity extending to a distance of about 2 mm. from the edge of the colony. Two were N.C.T.C. strains—*Cl. sordellii* and *Cl. centrosporogenes*. Seven were recently isolated from wounds; they were all very similar and were most nearly related to *Cl. bifermentans*, although some differed from it in motility, action on Spray's iron milk (1936), and liquefaction of inspissated serum. None fermented the two *welchii* sugars—lactose and sucrose. Although the cultures had been thoroughly purified by alternate broth and plate subcultures, it is possible that the positive reactions were due to contamination with small amounts of *Cl. welchii* whose growth was enhanced in the Nagler test fluid at the expense of the predominating clostridium. Serial subculture in this fluid improved the Nagler reaction to a certain extent, but all attempts to reveal traces of *Cl. welchii* in the subcultures of these strains have so far failed. With all 7 cultures large doses mixed with calcium chloride failed to kill mice or guinea-pigs. On the whole the similarity of these cultures and their persistent non-*welchii* characters in media favouring the growth of *Cl. welchii* suggest they are non-*welchii* Nagler-reacting clostridia. Nevertheless the fact that all but 2 of the cultures came from wounds that contained *Cl. welchii*, and the impossibility of establishing the absence of *Cl. welchii* in the cultures without the use of a single-cell culture method, at present preclude a definite answer. All that can be said with certainty is that a feeble Nagler reaction is given by a few cultures in which it has so far proved impossible to demonstrate *Cl. welchii* by ordinary bacteriological technique. In the light of this fact the appearance of a feeble reaction must for the present remain inconclusive.

Aerobes.—In routine tests, 3 haemolytic aerobic spore-bearers were Nagler-tested; 2 were feebly positive.

Value of the Test and its Interpretation

Well-defined strongly positive Nagler reactions reliably indicate *Cl. welchii*, and the test is an exceedingly useful addition to the routine litmus milk tests. It is much more easily elicited than the stormy clot. When single colonies are used as inocula 80% of strains of *Cl. welchii* give a strongly positive Nagler reaction on first testing, whereas only 45% give a stormy clot in litmus milk. Spray's iron milk (1936) is more sensitive than litmus milk, but the "stormy clot" is produced in this medium by a number of other clostridia—namely, *Cl. aerofoetidum*, *Cl. butyricum*, *Cl. multifermentans*, and occasionally *Cl. sphenoides*, *Cl. fallax*, *Cl. tertium*, and *Cl. septicum*. Hence the reactions in both milk media are less reliable than a well-defined Nagler reaction, which has the advantage of being serologically specific.

The test is effective, simple, and easy to apply, and yields results quickly with small amounts of materials. It cannot be used as the sole confirmation of an identification based on individual and colonial morphology because the feeble reactions given by some *welchii* strains are inconclusive.

A mixture of equal parts of Fildes's broth and human serum is preferred for the test. Being more sensitive to *welchii* toxin, yolk saline is a possible substitute for human serum, but it appears to be a poorer supporter of growth. Single-colony inocula are large enough for Nagler tests of all but the very poorest growers. They should be incubated until positive or up to three days; and they should not be recorded as negative until the growth has been good for at least two days. Centrifugation is necessary for accurate reading, but, in view of the occasional change in the specific gravity of the flocculent material, tubes must be read daily both before and after spinning.

For routine rapid identification the test should be applied to any colony suspected of being *Cl. welchii*, for there is a very good chance of obtaining a result in twenty-four hours. At the same time as the Nagler test is set up, a meat-broth culture should be sown and, if the first test is negative in twenty-four hours, used for a heavy

inoculum in a second test. This will probably yield a result by the second day. The test thus affords a method by which a positive specific result may be obtained within two or perhaps three days of taking the specimen.

Nagler reactions may be obtained on solid media. On Fildes's agar containing 10 to 20% human serum sixteen-hour colonies of *Cl. welchii* are surrounded by clearly defined zones of marked opacity 2 mm. wide. With longer incubation the zones extend, often up to 8 mm. By the addition of 4 units of *welchii* antitoxin per c.cm. of medium the formation of the zone is completely inhibited. (On antitoxin medium of this strength a few colonies of one *welchii* strain produced a thin ring of opacity about 0.2 mm. wide and about 1 mm. from the colony, apparently in the depth of the medium; it was completely inhibited by 24 units of antitoxin per c.cm.) The 7 Nagler-reacting cultures of *Cl. bifermentans* type, and the N.C.T.C. strains *Cl. sordellii* and *Cl. centrosporogenes*, produced a similar opacity, which sometimes required forty hours' incubation before developing; in confirmation of the finding of Cook (personal communication) *Cl. oedematiens* produced a similar neutralizable zone; all other anaerobes tested produced none at all. This adaptation of the Nagler reaction to a solid medium has already proved a useful means of detecting *Cl. welchii* within twenty-four hours of taking the swab. Test plates are more sensitive than test fluids; great caution must therefore be exercised in the interpretation of feeble or slowly developing plate reactions. A control antitoxin-containing plate is essential.

Summary and Conclusions

The production of a turbidity in human serum by the toxins of growing *Cl. welchii* (Nagler reaction) is a valuable aid to the rapid identification of the bacillus for diagnostic purposes. Excellent results are obtained with a mixture of equal parts of human serum and Fildes's broth incubated anaerobically. The seeding of a single *welchii* colony into such a mixture produced a strong reaction in 80% of the tests after one to two days' incubation. The reaction is specifically inhibited by antitoxin. Feeble reactions are not unequivocally indicative of *Cl. welchii*, since they are given by certain other species of anaerobic spore-bearer. Human serum-Fildes's-agar provides a means of detecting *Cl. welchii* on plates within twenty-four hours of taking a swab.

I am greatly indebted to Dr. Herta Schwabacher and Dr. A. C. Cunliffe for their help with tests of wound anaerobes; to Dr. E. T. C. Spooner for *welchii* strains; to Dr. C. R. Amies of the Lister Institute, Elstree, for antitoxin; to Dr. R. St John Brooks, Major MacLennan, and many others for strains of clostridia; and to Prof. A. A. Miles for interest and advice. The work was made possible by a personal grant from the Medical Research Council.

M. Kobro and P. Owren (*Norsk Med.* 1941, **9**, 447) state that trichinosis had not been seen in Norway since 1882 until the summer of 1940, when an outbreak of seven undoubted cases occurred at Strömmen, near Oslo. Six showed the classical symptoms of the disease, such as oedema of the eyelids, gastro-intestinal disturbance, stiffness of the muscles, pronounced eosinophilia, and fever. One had atypical clinical symptoms with gastro-intestinal manifestations, but with albuminuria and haematuria. The cause of the epidemic was the consumption of inadequately cooked pork. All recovered.

THE AFTER-TREATMENT OF PARAPLEGIC PATIENTS FOLLOWING INJURIES TO THE SPINE

BY

Lieut.-Colonel E. L. GOWLLAND, D.S.O., T.D., M.B.
Commandant, Star and Garter Home for Disabled Sailors, Soldiers, and Airmen

As the result of air raids there must now be in this country more cases of paraplegia following wounds and crushing injuries to the spinal column than ever before, especially amongst the civilian population. The immediate treatment of these most serious injuries is well known, but it may be emphasized that in first moving such cases it is wise to place the patient in the prone position on a stretcher or other means of transport, to prevent further crushing of the cord.

It is the after-treatment that is so important—that is, when the patient, having recovered from shock, having perhaps had a laminectomy performed to remove spicules of bone or to relieve pressure from the cord, having in many cases, especially among the males, had cystotomy, with suprapubic drainage and the like, has settled down and become accustomed to a paraplegic existence. After complacency has been established, life in these cases is not necessarily miserable, but it is full of surgical and medical pitfalls, the avoidance of which is essential to the preservation of a reasonable degree of comfort.

Let us, then, consider the treatment when the spinal injury has not resulted in speedy death. A very small proportion of these patients recover completely; but most of them remain paralysed, and in these cases the after-treatment here to be suggested will enable them to be comparatively free from pain, to enter happily into sedentary occupations and games, and to be mentally normal. The essentials are: (1) to ensure against infection of the urinary tract; (2) to guard against trophic ulcers and bed-sores; (3) to mitigate the serious discomfort of the incontinences; and (4) to make provision for adequate sleep and deal with mental anxieties by giving suitable sedative medicines.

Infection of the Urinary Tract

The "end" condition in nearly all paraplegics is a pyelonephritis with uraemia (in the absence of intercurrent disease, to which they appear to be no more subject than normal individuals). Patients often present a condition of retention with overflow, and these cases call for suprapubic cystotomy, which they usually get. But there has been a practice of inserting through the suprapubic opening a de Pezzer or Malecot drainage tube and letting it do its own work quite indefinitely, without daily irrigation of the bladder and frequent removal and sterilizing of the tube.

All such cases develop a mixed infection of the urine, very many have bladder calculi, and most have a pyelitis. Here we cast out these self-retaining tubes and insert a 12-inch or 16-inch sterilized Jaques catheter into the suprapubic wound. Another catheter is placed daily in the urethra and connected with a tube from an irrigator, which is hoisted about 2 feet 6 inches above the bladder, and the "wash-out" with boric or some similar lotion is carried out via the urethra, through the bladder, and out by the suprapubic tube. This is a reversal of the usual method of irrigation, but many years of experience have convinced me of its efficacy. A fresh suprapubic tube is now inserted, being fixed by strapping to the abdominal wall; it is then connected by a double clip with another tube leading to a urine bottle attached

to the side of the bed. When these patients are up in their wheel-chairs or hand-propelled tricycles the tube is connected with a rubber urinal suspended from the waist and strapped on to the leg. As most of these patients have no feeling below their lesion the removal of calculi from the bladder is easy and does not call for an anaesthetic.

The daily toilet of the bladder is the essential detail in the treatment of paraplegics. Most cases are given mixtures as follows: (*a*) 20 grains of acid sodium phosphate in one ounce of water thrice on one day, followed by (*b*) 10 grains of urotropine in water thrice on the next day; and so on indefinitely on alternate days.

Trophic Ulcers and Bed-sores

A trophic ulcer is due to lack of circulation or to deficient innervation of the skin. A bed-sore is a nursing crime. We do not have bed-sores in this Home! A trophic ulcer is an inevitable occurrence and cannot be healed, but it can be kept surgically clean.

When a paraplegic patient arrives he must be put to bed, using fracture boards, an air bed, or, better still, a "dunlopillo" mattress, and at once his palsied limbs must be placed in the optimal position by means of cushions, sandbags, and the like, to avoid hyperextension or hypercontraction. The usual daily nursing measures must be adopted for the health and preservation of the skin, especially in those parts subject to pressure. A bed-cradle should always be used to keep the weight of bedclothes off the badly nourished and paralysed lower extremities. Remember that the patient can feel nothing "below the belt"; it is therefore imperative that constant watch be kept on the sacral region, the hips, and the lower extremities, so that any redness or excoriation may be treated without delay.

When the vertebral lesion has consolidated—say some eight to twelve months after the injury—it is well to encourage the paraplegic to sit up and get about in a wheel-chair or a hand-propelled or motor tricycle; but these patients must have padded seats and plenty of cushions to protect their not too well nourished seating apparatus. At this period, too, we advocate two or three baths a week. This does them good; it stimulates the peripheral circulation and relieves the kidneys of some of their burden. We have our baths at right-angles to the walls so that an orderly on each side can expedite and assist in the process.

Massage certainly increases the cutaneous and muscular tone, and even after years of disability it conserves hope and at any rate induces the patient to feel that something is being done. *Electrotherapy* I do advise in the early stages, and until it has been conclusively ascertained which groups of muscles are worthy of notice and therapeutic attack, but I consider that to continue electric treatment to irresponsive muscles is a waste of time and electricity.

The Incontinences

Incontinence of Urine.—In the male this is readily managed by the provision of a recognized pattern of rubber urinal having a penile sheath connected with a tube to a container which is strapped to the leg and emptied by a tap near the ankle. For the female I fear there is no adequate provision. The few cases of urinary incontinence in women that I have met with have been difficult to deal with adequately, and in spite of all sorts of apparatus and trials the condition is likely to be appalling. No doubt something will soon be done about this: it is very urgent.

Rectal Incontinence.—When these paraplegics have as it were settled down—say a year or two after their wounds—and they are able to get about in chairs and tricycles, we have found that a weekly or bi-weekly day in bed is most useful. We call these "enema" days—when patients are given a high colonic injection of water, soap, and turpentine to empty the large bowel; this enables them to exist the remaining days of the week without incontinence. They can therefore go to entertainments, cinemas, etc., with almost complete confidence that there will be no unpleasant happenings.

Shock, Sleep, and Pain

In the early stages enough sedatives must be given to counteract shock, which is intensified by the contemplation of years of inaction and invalidism. Bromides are valuable. If these do not work, morphine may be necessary; but it is so easy for the paraplegic to become a morphine addict that I seriously counsel the withholding of its use unless pain is unbearable.

These people must have sleep: dial, adalin, soneryl, and all sorts of others may be used, but you may finally have to resort to morphine.

Conclusion

There are two points to remember: (1) in the initial stage the freeing of pressure on the spinal cord by laminectomy; (2) the unremitting nursing care of the whole body of the patient; and especially the daily toilet of the urinary tract, which of itself can prolong life for these unfortunate people.

After nearly seventeen years in charge of this Home for Paraplegics and after many years of direction in the management of these cases by the late Sir John Thomson-Walker, I feel that perhaps I may be forgiven for appearing didactic.

INTRAVENOUS ANAESTHESIA IN OBSTETRICS

BY

KENNETH M. ROBERTSON, M.D., M.R.C.P.

Honorary Physician, Royal Hants County Hospital, Winchester

In general practice, especially in times like these, obstetric operations have usually to be conducted with only the nurse or midwife as assistant. The difficulty and anxiety so often experienced with inhalation anaesthesia under these conditions led me, some four years ago, to a trial of intravenous anaesthesia as an alternative. It seemed to me that this method would add enormously to the patient's comfort, while at the same time it would very largely free the nurse, who, being relieved of the duties of anaesthetist, would be able to supply that extra pair of hands so invaluable.

Choice of Evipan

Evipan was chosen because it had been employed freely in all kinds of case. I used this drug throughout this series, having found no reason to change it.

I first tried evipan in cases needing repair of the perineum, and it gave complete satisfaction. I then employed it in low-forceps operations. I have given it in over 50 cases, and only once have I had to reinforce anaesthesia with open ether. The ideal case is that in which the head is on the perineum, when, with the aid of a small pair of forceps, such as those used and described by Wrigley, labour can safely be shortened. It was in just such a case that the unpleasantness and inconvenience of open ether or chloroform seemed often to outweigh the relief and advantages to patient and practitioner alike.

Some of the more difficult obstetric operations have also been carried out with evipan, with complete satisfaction so far as anaesthesia is concerned. One patient, a primi-

para, was delivered of a breech with legs extended, a leg having to be brought down. The child did very well, and the mother suffered no undue shock. In 3 cases persistent occipito-posterior positions have been manually rotated and delivery made with forceps, without undue hurry being experienced, and neither mother nor child appeared to suffer in any way.

In 6 cases the head was found to be unexpectedly "tight," and considerable traction was required to deliver the child. In 4 of these a perineal tear resulted, but this was repaired without any additional anaesthetic.

Evipan has been given, in rather smaller dose, to 7 patients just before the birth of the head, when forceps were not used. In one case trouble was experienced with the child after delivery—there being some delay in respiration. In the other 6 cases the children cried at once and there were no neonatal complications. In no case was there any excessive post-partum bleeding, and the placenta always appeared to separate quickly and easily.

Description of Technique

The technique which is now adopted has been modified with increasing experience, and I hope that the following brief description may be of value to others.

Having decided to deliver the patient, she is placed in the left lateral position and obstetric aid straps are applied. The type used has been that described by C. J. Penny (1933): one strap encircles the abdomen and is affixed to the head of the bed; the other holds the patient's hips flexed and passes over her neck. The buttocks and perineum are then thoroughly swabbed with dettol cream, and a swab covered liberally with dettol cream is left in the vagina.

The operator, gowned and masked and with bare washed hands, is now ready to administer the evipan. A prop is placed between the patient's jaws, and the nurse, standing by her head, helps in steadying the arm: a firm grip above the elbow will make the veins in the antecubital fossa more obvious. In every case 10 c.cm. of the 10% solution of evipan has been used. The first 3 or 4 c.cm. is injected quite quickly, and after a pause the remainder of the dose is given rather more leisurely —about a minute being taken over the whole procedure. In all my cases I have had the help of only the nurse or midwife; she remains at the patient's head, holding the chin well forward, and from the same position she is able later to support the patient's right leg by taking hold of the strap.

The operator now re-washes his hands and dons sterile gloves. The dettol cream swab is extracted from the vagina and is used for one last application to perineum and buttocks. Sterile towels are then used to cover exposed areas, after which a catheter is passed, the receiver being held by the nurse, who has it ready beside her. At this stage the forceps are applied to the child's head and the extraction is carried out in the ordinary way. When there has been the need for earlier sedation by chloral and bromide, or morphine, a very complete anaesthesia has been experienced, with a patient perfectly still. In one or two cases in which there has been no previous medication slight movement of the legs has been experienced, and it is for this reason that the obstetric straps are advised; for with them I have never been in any way inconvenienced by this tendency to move.

As has already been said, the children give no trouble; the third stage is passed rapidly, and the patient is usually recovering consciousness by the time one is ready to leave her. One of the ergot preparations is injected after the birth of the placenta, and it is always my practice to record the systolic blood pressure before leaving the patient. Readings of under 100 mm. Hg (which have not been met with in this series) should be taken as a warning of incipient shock and should be countered by the usual methods.

During the past six months this method of anaesthesia has been adopted by Dr. C. J. Penny, honorary obstetrician to the Royal Hampshire County Hospital. He tells me that he has used it in over 20 cases, and that it has been uniformly satisfactory.

Summary

The advantages of intravenous anaesthesia in the easier obstetric operations are discussed.

In over 50 cases in which evipan sodium in 1-gramme doses has been used it has given entire satisfaction, and there have been no complications in the progress of mother or child.

A brief account of the technique is given.

EFFECT OF BENZEDRINE ON THE OCULOGYRIC CRISES OF PARKINSONISM

BY

H. LOVELL HOFFMAN, M.B., M.R.C.P., B.Ch

Honorary Medical Registrar, Royal United Hospital, Bath; Acting Surgeon Commander, R.N.V.R.

In the last few years several articles have appeared in American medical journals reporting the beneficial results which may be expected when benzedrine is administered in conjunction with stramonium or hyoscine to cases of post-encephalitic Parkinsonism (Solomon, Mitchell, and Prinzmetal, 1937; Finkelman and Shapiro, 1937; Matthews, 1938; Davis and Stewart, 1938). Of the symptoms discussed it would appear that oculogyric crises react best to this treatment—in fact, three of the four articles referred to claim that this symptom was relieved in every case in which it occurred.

The investigation described below was carried out on patients at the National Hospital for Nervous Diseases, Queen Square, and at the Royal United Hospital, Bath, in an attempt to reproduce these uniformly good results. It is impossible to control an investigation of this type accurately, certain criticisms of the dosage, and the shortness of the period of observation in some cases, being bound to arise. It is felt, however, that by concentrating on an isolated symptom, such as the oculogyric crisis, which can be recorded by the patient, a more accurate impression of the effect of benzedrine on post-encephalitic Parkinsonism will be obtained than by considering rigidity, tremor, or sleep disturbance, which are obviously more difficult to assess.

Seventeen patients were observed while under treatment with stramonium, hyoscine, or some similar drug, and a record was kept of their oculogyric attacks over periods ranging from two to twelve weeks. Benzedrine was then given in various doses up to 30 mg. a day in addition to the previous treatment, and the attacks were again recorded over similar periods. In two cases benzedrine was given alone.

In the table the average number of attacks per week is stated, as it is considered that this method will give the most accurate comparison between the cases. It should be realized, however, that in patients showing a small number

of attacks this figure will not give such a true indication of the response to treatment as in those with a larger weekly average.

Summary of Results

The results of the 17 cases treated were as follows: good, 4 (23.5%); moderate, 5 (29.4%); poor, 8 (47.0%).

Table of Results

No	Sex and Age	Treatment	Average No. of Attacks per Week	Remarks	Result
1	M. 20	Extr. stramon. sic. 0.25 mg., q.d.s.	3.0		
		Original treatment + benzedrine 10 mg. b.d.	1.4	No improvement in other symptoms	Moderate
		Original treatment only	2.5	Stated that he missed benzedrine	Relapse when benzedrine stopped
2	F. 31	Placebo	1.3		
		Tr. stramon. ℥xxx, tr. nucis vom. ℥x	0.75		
		Above treatment + benzedrine 10 mg. b.d.	1.25	Attacks of shorter duration	Nil
		Benzedrine increased to 15 mg. mane, 10 mg. midday	1.0		Increase in attacks when benzedrine stopped
		Tr. stramon. and tr. nucis vom. only	5.0		
3	M. 35	Extr. stramon. sic. 0.25 mg. b.d.	1.83	B.P. 165/105	
		Original treatment + benzedrine 5 mg. b.d.	1.33	Dizziness if benzedrine taken on empty stomach. Thought he was much improved	
		Original treatment only	1.33	Said there was not much difference when benzedrine stopped	Nil
4	F. 19	Tr. stramon. ℥xxx, ac. hydrobrom. dil. t.d.s.	1.0		Good
		Original treatment + benzedrine 10 mg. b.d.	0.25	General improvement	Some improvement maintained when benzedrine stopped
		Original treatment only	0.5	Said she missed benzedrine	
5	M. 22	Hyosc. hydrobrom. gr. 1/100, atropin. sulph. gr. 1/250, tr. stramon. ℥xxv, t.d.s., luminal gr. 1/2 b.d.	2.0		Good
		Original treatment + benzedrine 10 mg. b.d.	1.25	Said benzedrine improved symptoms, but did not miss it when it was stopped	Improvement maintained when benzedrine stopped
		Original treatment only	1.5		
6	F. 22	Hyosc. hydrobrom. gr. 1/100 t.d.s.	0.67	B.P. 150/75	
		Original treatment + benzedrine 10 mg. b.d.	1/1.33	Did not take benzedrine regularly. Morning headache while taking it	Nil
		Original treatment only	0.67		
7	M. 23	Tr. stramon. ℥xlv t.d.s.	1.5	Attacks lasted 1 hour each	Moderate
		Original treatment + benzedrine 5 mg. b.d.	1.1	The majority of attacks lasted 1/2 hour each	Improvement maintained when benzedrine stopped
		Original treatment only	1.0	Said tremor was worse without benzedrine	
8	F. 27	Extr. stramon. sic. 0.25 mg. t.d.s.	2.5		
		Original treatment + benzedrine 5 mg. b.d.	1.5		Ditto
		Original treatment only	1.62		
9	M. 27	Tr. stramon. ℥lx, hyosc. hydrobrom. gr. 1/100, t.d.s.	2.0		Moderate
		Original treatment + benzedrine 10 mg. b.d.	1.25		Improvement on benzedrine and stramon. and hyosc.
		Benzedrine increased to 15 mg. mane, 10 mg. midday	1.5		Worse on benzedrine alone
		Benzedrine 15 mg. mane, 10 mg. midday, given alone	3.0		Improvement maintained when benzedrine stopped
		Original treatment + benzedrine 15 mg. mane, 10 mg. midday	2.0	No attacks for 14 days, then 4 attacks in 14 days	
		Original treatment only	0.75		

Table of Results (continued)

		Original treatment + benzedrine 5 mg. b.d.	3.4	Still sleepless	
16	F. 22	Acid. hydrobrom. dil. ℥v, tr. lobelia ℥v, tr. stramon. ℥xxx t.d.s., tab. luminal gr. 1/2 nocte	6.5		
		Original treatment + benzedrine 10 mg. b.d.	6.0		Nil
		Original treatment + benzedrine 15 mg. mane, 10 mg. midday	7.25		
		Original treatment only	6.0		
17	M. 22	Hyosc. gr. 1/100 b.d.	1.0		
		Original treatment + benzedrine 5 mg. b.d.	0.75	Palpitation. Pulse 136. B.P. 125/70. No cardiac enlargement, but had a generalized systolic murmur and accentuated pulmonary second sound. Tachycardia persisted some months. Signs suggested mitral regurgitation	
		Original treatment + benzedrine 10 mg. b.d.	0.75		
		Original treatment — benzedrine 10 mg. mane, 15 mg. midday	0.75		Nil
		Original treatment — benzedrine 15 mg. b.d.	1.0		

This shows some degree of improvement in 53% of cases. In Cases 1, 2, 11, and 13 the attacks increased when benzedrine was stopped. In Cases 4, 5, 7, 8, and 9 some improvement was maintained when benzedrine was

stopped. In Cases 9 and 11 benzedrine was given alone: Case 9 was worse, but improved when the treatment was combined with stramonium and hyoscine; Case 11 improved but a better result was obtained when belladonna and stramonium were given as well. Of the cases not improved, one (Case 14) gave a history of head injury and showed a strongly positive Wassermann reaction.

Complications.—In 2 cases of mild hypertension one patient complained of dizziness (Case 3) and one of headache (Case 6). In 2 cases of mitral disease one patient complained of pain in the chest (Case 11) and the other (Case 17) developed a persistent tachycardia which resisted treatment for a considerable time. Only one patient complained of sleeplessness.

Discussion

These results confirm the general impression that in the oculogyric crisis of Parkinsonism benzedrine acts better if combined with drugs such as stramonium or hyoscine. It is interesting to note that 5 patients maintained their improvement even when the drug was stopped and they returned to their original treatment. This, of course, may have been merely coincidence.

In considering the complications which occurred, it would appear necessary to exercise caution in those cases which show signs of hypertension or heart disease, as it will be noted that certain symptoms, including a prolonged tachycardia, occurred in such cases.

The results obtained by American authors are summarized as follows:

Author	Dosage of Benzedrine	Percentage of Cases Improved	No. of Cases Treated
Solomon, Mitchell, and Prinzmetal (1937)	10-20 mg. b.d, or t.d.s. (gave up to 160 mg. p.d.)	100%	8
Finkelman and Shapiro (1937)	20-30 mg. p.d.	100%	7
Matthews (1938)	15-90 mg. p.d.	Improvement reported	?
Davis and Stewart (1938) ..	40-60 mg. p.d.	100%	23

It will be seen that comparison can only be made with those cases described by Finkelman and Shapiro, who gave doses of benzedrine similar to those employed in my own series. I was unable to reproduce their uniformly good results, having had 53% successes as against the 100% which they reported. The remaining three groups of American workers used much larger doses, and I cannot from personal experience say if correspondingly good results would have been obtained had I given similar amounts of benzedrine in my cases.

Conclusions

Benzedrine, even in small doses, may be expected to give relief to about 50% of patients with oculogyric crises if administered with drugs of the belladonna group. Larger doses are worthy of trial if a careful watch is kept on patients with cardiac disease or hypertension.

My thanks are due to the honorary staff of the National Hospital, Queen Square, for allowing me to publish cases which I treated while assistant medical registrar to that hospital, and to Dr. R. G. Gordon of the Royal United Hospital, Bath, for his permission to include Case 17. I also wish to thank Messrs. Menley and James, who kindly supplied the benzedrine used in the investigation.

Clinical Memoranda

Treatment of Varicose Ulcer with Eczema

To-day the standard treatment of varicose ulcers is by "elastoplast." There are, however, a certain number of cases that are intractable; they appear to be those complicated by eczema. The skin is degenerated, being shiny, purplish, and scaly. Here are four case histories, the first three being consecutive.

CASE REPORTS

Case 1.—A woman aged 45 had "white leg" following pregnancy seventeen years previously. An ulcer appeared two years later, and persisted until June, 1939, when treatment by elastoplast was started. It was 3 in. by 4 in. in area, and was situated about 2 in. above the internal malleolus. After a year the ulcer measured 2 in. by 1 in. Further treatment failed to reduce its size, and another smaller but very painful ulcer, about one-half inch across, appeared. The whole leg was the seat of eczema by now. Treatment by reversed elastoplast was tried without success. In despair a "viscoplast" bandage (a bandage impregnated with Unna's paste) was applied in three thicknesses. It was painful at first, but after a few days the pain ceased. About this time the patient was confined to bed for two weeks on account of laryngeal spasm. A certain amount of discharge occurred: this was absorbed by packing with wool. On removal three weeks later the ulcer had almost disappeared, and a second application resulted in a complete cure. For the last six months she has worn a crêpe bandage. Apart from the two weeks in bed, which was a help, she has done her ordinary work as a farmer's wife.

Case 2.—A woman aged 64 had suffered from a varicose ulcer off and on for twenty-nine years. When she came for treatment it was the size of a shilling. Elastoplast was applied twice in five weeks, and resulted in great improvement, but she refused to have it applied again. Viscoplast was tried, with the result that the ulcer healed soundly—the first occasion since it appeared. She did her work all the time.

Case 3.—A woman aged 67 had a small painful ulcer over the internal malleolus, with degeneration of the surrounding skin. Here "viscoplast" was applied at the outset, causing much pain for the first few days. It was left in position for three weeks, when the ulcer was found to be soundly healed. She was able to do her housework after the first few days.

Case 4.—A man aged 65 had for six years the worst varicose eczema I have seen. An abscess had formed over the patella, possibly the result of septic absorption. "Elastoplast" was applied twice with some benefit, then followed two applications of "viscoplast," each kept on for three weeks. The man, a butcher, is on his feet a great deal, but directly the abscess over the patella had healed he carried on with his work. He now wears a crêpe bandage, and declares he is better than for years. The skin is still purplish, but is not ulcerated or scaly.

London, W.1. A. P. BERTWISTLE, F.R.C.S.Ed.

An award of the Dr. Jessie Macgregor Prize in Medical Science will be made in July to the applicant who presents the best record of original work in the science of medicine. Such work may be published or unpublished, but must not have been published earlier than three years prior to July, 1941. The value of the prize is not less than £50 and is open to medical women who are graduates in medicine of the University of Edinburgh, or who have taken the Scottish triple qualification, and who, before becoming qualified, have studied medicine for at least one year in Edinburgh. The successful applicant shall, within six months following the award, deliver a lecture to the medical profession in Edinburgh on the subject of the work for which the prize has been awarded, such lecture to be entitled "The Dr. Jessie Macgregor Lecture." Applications marked "Dr. Jessie Macgregor Prize" must reach the Convener of Trustees, Royal College of Physicians, Edinburgh, 2, not later than June 30.

Reviews

THE DIFFICULT CHILD

The Doctor and the Difficult Child. By William Moodie, M.D., F.R.C.P., D.P.M. (Pp. 214. $1.50, or 8s. 6d net.) New York: The Commonwealth Fund; London: Oxford University Press. 1940.

Dr. Moodie has written a book on the difficult child which is characterized by his usual lucidity and sound common sense. Published by the Commonwealth Fund of America, which has so generously supported child guidance in this country, this small volume sets out the principles and practice of child psychiatry in simple terms and without any noticeable bias towards any of the extreme schools of modern psychology. The first part deals with general principles. The difficulties presented by children are very varied, and only long experience will ensure that the significance of these is properly evaluated. The child and his parent must be regarded as a unit, although the child is also an individual. He demands, and has the right to, love and security and understanding: and if the parent cannot give these then it may be the parent who requires treatment. Dr. Moodie is one of those who believe that many of the problems of childhood are much less complicated than some would have us believe, and that adjustment of the environment is often the main requisite, with some guidance of parent and/or child on how to meet the situation, but he does not neglect the less common case when there is a profound disturbance of the child's own emotional life which can only be resolved by careful treatment of the child himself.

The second part of the book deals with specific problems such as stealing, lying, sex misdemeanours, truancy, and so on in the emotional field. Psychoses in children and mental deficiency are briefly dealt with, and the very important subject of educational backwardness is more adequately presented. Brief case histories are given to illustrate the various subjects touched upon, and this prevents the brevity of the presentation from resulting in dullness. This is a book which can be confidently recommended to both medical and lay readers: they will learn from it all that needs to be known about the difficult child by those who do not profess to be experts.

ABDOMINAL OPERATIONS

Abdominal Operations. By Rodney Maingot, F.R.C.S. Volumes I and II. (Pp. 1,385; illustrated. £5 the set.) New York and London: D. Appleton-Century Company. 1941.

Except that the covers are green instead of blue, this two-volume book is reminiscent in size, shape, and print of the last edition of Moynihan's classical two-volume contribution to abdominal surgery, published in 1926. Here, however, the resemblance ends, for the present book lacks the clarity of presentation and mastery of diction of the great Leeds surgeon. It is none the less a thoughtful and carefully prepared work, well written, and pleasing in many particulars, one of the chief of which is the illustrations. There are for the most part excellent wash drawings made by Miss Lariviere, and they also include some of Mr. Thornton Shiell's well-known work in the form of coloured plates of pathological specimens. Chapters on sternal puncture and post-operative chest complications are written by Drs. L. T. Bond and R. Sleigh Johnson respectively; otherwise the work is that of a single author, Mr. Rodney Maingot, who, however, freely intersperses throughout the text quotations in small print from important original contributions such as those of Wilkie on acute appendicular obstruction and Ernest Miles on cancer of the rectum. An index of quoted authors is not included, and the subject index is far from complete. Proof-reading might have been better; the legend to Fig. 93 on page 453 is "Stamm's gastrectomy," and should obviously be "Stamm's gastrostomy."

In certain discussions on treatment several operations are described, but no very clear lead is given as to which is the best of these and what the author's experience of the alternatives has been; thus in irreducible intussusception seven methods of treatment are mentioned, with the statement that all are associated with a high mortality, and the surgeon must obviously decide at the operating table which method will give the patient the best chance of recovery. But how is he to decide? If this work is to help the young surgeon confronted with such a problem some further comment is highly desirable, and Elliot-Smith's important paper (*Lancet*, 1935, 1, 992) on the outstanding value of lateral anastomosis in such cases might have been quoted with profit. We looked in vain for authoritative accounts of errors of rotation of the gut, of portal pylephlebitis, and of attempts at treatment of this condition by mesenteric venous ligature and the use of sulphonamides Disappointment in some directions, however, is largely compensated by full and interesting accounts of other abdominal lesions, and the account of gastric resection is perhaps one of the best parts of the book. Abdominal incisions and diseases of the vermiform appendix are well done, but we would like to have seen acute appendicular obstruction as a subheading to acute obstructive appendicitis, since it should surely be our object to recognize and treat the obstructive lesion before it becomes an inflammatory condition, as it invariably does if not dealt with very promptly. It is interesting to note that the author expresses strong belief in the occurrence of chronic appendicitis, and regards it as comparatively common. Prof. Grey Turner's important paper in *Chirurgica Scandinavica* (1932) might have been quoted on conservative resection of the rectum with preservation of the anal sphincter. We would also like to have seen the thorny subject of abdominal adhesions and their prevention discussed at some length, and some indication given as to the value of sulphonamide therapy administered by intraperitoneal and oral routes in inflammatory lesions. A complete chapter on anaesthesia for abdominal operations would be a useful contribution to a further edition.

Volume I deals with abdominal incisions, stomach and duodenum, spleen, pancreas, and the gall-bladder and bile ducts; Volume II with the liver, vermiform appendix, peritoneum, mesentery and omentum, external abdominal hernia, the intestines, and post-operative chest complications. There is, notwithstanding the points we have raised, much valuable material in this book, which should make its appeal to the thoughtful abdominal surgeon.

LOCAL GOVERNMENT ADMINISTRATION

The Municipal Year Book and Encyclopaedia of Local Government Administration, 1941. Edited by James Forbes. With a preface by the Right Hon. Malcolm MacDonald, M.P., late Minister of Health. (Pp. 1,443. 40s. net.) London: The Municipal Journal, Limited. 1941.

There is something very buxom and comforting about the appearance of the *Municipal Year Book* for 1941. It is as ample as ever—weighs four and a half pounds and has fourteen hundred pages packed with information about the various aspects of local government. It is all so normal, so traditionally English. One feels that whatever may change in British society, municipal institutions will remain. The town clerk is six hundred years old and is

support for the Jacksons' prejudice against tobacco and alcohol, it is hard to believe that the aetiology is as simple as this. The subject has been studied by StClair Thomson,[6] who weighed and compared all the many possible predisposing causes. He concluded that there was no definite proof in favour of any of them, and this conclusion still holds good. All forms of chronic irritation, including uncommon ones such as keloid scars and the results of poisoning by mustard gas, seem at times to enter the sequence of cause and effect. But statistical research is subject to so many errors requiring an unknown amount of correction that it is difficult through this method to obtain any exact or detailed information.

PLASMA PROTHROMBIN AND VITAMIN K

In a series of annotations we have kept readers informed about the rapid growth of knowledge of plasma prothrombin and vitamin K and their relation to haemorrhage in jaundice and the newly born, and the review by Brinkhous[7] which has lately appeared leaves very little new to say. The emphasis is on the physiology and biochemistry of prothrombin, and its exact role in blood clotting, which is still not clear. Prothrombin can be isolated in a fairly pure state, but the methods of extraction from plasma are very incomplete and cannot be used as a basis for quantitative estimation. Prothrombin is therefore determined indirectly by its power to form thrombin, which initiates the coagulation reaction. Brinkhous prefers the two-phase method of determining prothrombin, which has been used in his laboratory and which corresponds with the actual clotting process. The prothrombin is first converted into thrombin, and the amount of thrombin is then estimated by its ability to coagulate a fibrinogen solution. The clinical pathologist usually estimates prothrombin by the accelerated clotting test (Quick), which depends on the speed of clotting of plasma or blood when an excess of thromboplastin is added; or by Dam's test, which depends on the amount of thromboplastin necessary to produce a standard clotting time. Both these methods work fairly well in practice, but they assume that the prothrombin conversion time is a constant. This is certainly not true of different species, and it is almost certainly not true of members of the same species. For example, there are marked and constant differences in the plasma prothrombin level of infants as obtained by the one-stage and two-stage methods. Dam's test involves more assumptions, and the values obtained seem to be related less intimately to the plasma prothrombin level than in Quick's test or its various modifications. The important point for the clinician to remember is that, whereas a prolonged prothrombin time always spells trouble, a normal prothrombin time does not necessarily mean security from cholaemic bleeding. The clinical pathologist will continue to look for methods of making the tests more accurate and simple. Hobson and Witts[8] have suggested an artificial thromboplastin composed of Russell-viper venom and lecithin, while Souter, Kark, and Taylor[9] use brain emulsion which has been dried by the lyophile technique. This method has leaped into popularity as a result of its use for drying serum and plasma for transfusion, and there seems no reason why some of the troublesome biological reagents for the two-stage prothrombin test should not be similarly prepared.

Brinkhous describes four forms of vitamin K, which are all naphthoquinone derivatives. Vitamin K_1 comes from alfalfa extracts, vitamin K_2 from putrefying fish meal, and thiocol or K_3 from bacteria, while the synthetic vitamin K_4, which is the most potent variant and the one now used in therapeutics, is 2-methyl-1:4-naphthoquinone. Much work still remains to be done in determining the most appropriate form and route of administration in man, the dosage, and the speed of action. Vitamin K_4 is insoluble in water, but it can be given parenterally dissolved in oil[10] or as a compound with sodium bisulphite, which is water-soluble.[11] The parenteral route is probably the best, as it avoids the difficulty of absorption by mouth and the need to give bile in addition. The methods of prophylaxis and treatment of the haemorrhage of the newly born also need more experience before treatment can be standardized, and though the importance of the whole-blood injections may be diminished, it is not yet certain that they can safely be omitted if bleeding occurs.

HORMONES AND PSYCHIATRIC DISTURBANCES

The relation between the endocrine glands and the psychoneuroses and psychoses is being approached from two standpoints—that of the endocrinologist and that of the psychiatrist. The endocrinologist cannot fail to notice the association of psychoneurotic symptoms with primary endocrine disorders or adjustments, and the abolition of such symptoms with appropriate endocrine therapy. This is obvious at the climacteric in the female, and in such endocrine disorders as hyperthyroidism, myxoedema, virilism, Addison's disease, and Fröhlich's syndrome. The existence of a male climacteric is not universally accepted, but where symptoms analogous to those of the female climacteric are found the response to testosterone may be as dramatic as that which follows its use in the complete male castrate. In using the term "psychoneurosis" as associated with endocrine disorders one also includes changes in behaviour and personality. In the experience of the endocrinologist it is comparatively rare for a psychosis to result from an endocrine disease—so rare as to make one suspect, when the two are associated, that there was a previous constitutional predisposition to psychotic disorder. Nevertheless, in such conditions as thyrotoxicosis and myxoedema manic-depressive disorders do occur and sometimes respond to early and adequate correction of the endocrine disorder. Similar observations might be applied to the climacteric, but in view of the millions who pass through the climacteric without the slightest suggestion of psychotic disorder it seems unlikely that the climacteric can be more than a subsidiary factor in the development of a psychosis at this period. From another approach—namely, that of psychiatry—Mott was the first to point to the degeneration of the testis in dementia praecox. With increasing knowledge of endocrinology and the availability of specific sex hormones, the psychiatrist's interest has been quickened, and a spate of articles are beginning to appear in psychiatric journals, some less critical than

others. Some investigators undertake laborious biological assays of the excretion of oestrone, androsterone, gonadotrophin, etc., in the urine, in an endeavour to establish scientifically the existence of an underlying endocrine deficiency or hyperactivity. The fact that oestradiol and testosterone are secreted by the adrenals as well as by the gonads complicates the interpretation of results, but useful data should accumulate. A greater difficulty is that of cause and effect, as it is well known that hormone activity can be completely suppressed by psychic factors (for example, early amenorrhoea in anorexia nervosa), and, further, that degeneration from secondary avitaminosis occurs in endrocrine glands when psychogenic anorexia is present over a long period. Neustadt and Myerson[1] have undertaken urinary assays in various "neuropsychiatric disturbances," using calorimetric methods of assay. In an examination of thirty schizophrenics they find that the values for oestrone and androsterone "range from very low to very high," and the results do not warrant any conclusion. Comparing six patients with involutional melancholia with six normal controls, they find variations in hormone excretion in both groups are of similar order, and "we may tentatively conclude from our findings that hormonal regression, if present, is an accompanying and *not a pathogenic factor of the depressive psychosis in the* sixth decade of life." They also obtained negative results in hormone therapy of involutional psychoses. In male homosexuals (using a criterion of "overt homosexual conduct as the predominant and preferred sexual activity, with or without physical stigmata") Neustadt and Myerson found that "there is either a deficit of androgens combined with a normal amount or excess of oestrogens, or there is a normal amount of androgens combined with an excess of oestrogens," but "treatment of a few cases by testosterone injections produced no essential change in the homosexual feelings or conduct, although the urinary findings were changed." In psychogenic impotence associated with neurosis and not including psychotic cases, there was low excretion of androgens and oestrogens in eight of twenty cases, but there was no appreciable improvement in symptoms in the only two cases treated with testosterone. This is in accordance with other observers' failure to influence psychogenic impotence with testosterone. A surprising finding is "a very high hormone level of both androgens and oestrogens in five out of six male masturbators." Rubinstein, Shapiro, and Freeman[2] report the treatment of morbid sex craving in five females with 25 mg. of testosterone propionate injected thrice weekly, and claim good results in four. It is true that testosterone will, in certain circumstances, neutralize the biological effects of oestradiol, which latter may experimentally stimulate sex behaviour in the female; but, on the other hand, it has also been found that testosterone produces hypertrophy of the clitoris and heightened erotic sensitivity in that region in some cases. Hemphill and Reiss[3] investigated the state of endocrine function in thirty cases of involutional melancholia occurring at the menopause. They find symptoms of ovarian, thyroid, and adrenal dysfunction in the majority, but emphasize the complexity of the problem. Treatment with follicular hormone and corticotrophic hormone appeared to give promising results in some patients. The authors venture to suggest on clinical grounds, and from assay of gonadotrophic hormone in urine and results of therapy, that "disturbances of the activity of the anterior lobe of the pituitary are largely responsible for the protean characteristics of involutional melancholia." No one would deny that an interesting field of investigation is being opened up, but it is also obvious that great caution is called for in examining the results. It would be a mistake to ask too much of the science of endocrinology when applied to psychiatric problems.

OCULAR PALSY IN PITUITARY ADENOMA

It has been generally held that paralysis of the ocular nerves is not caused by pituitary adenoma, and that the nerves escape because they are protected by the carotid artery from lateral pressure by the tumour. Involvement of the ocular nerves does, however, occur, but the question often arises whether patients with ocular palsy are suffering from suprasellar tumours rather than from pituitary adenoma. Weinberger, Adler, and Grant,[1] in a review of the literature and a study of fourteen cases, conclude that not only are there signs of involvement of the outer wall of the cavernous sinus in a good many cases, but these signs may be the first or predominant feature. Pressure on the outer wall of the cavernous sinus shows itself clinically by pain along the first division of the fifth nerve and by various degrees of involvement of the third, fourth, and sixth. This syndrome, known as the sphenoidal fissure syndrome, was first described in relation to pituitary adenoma by Foix in 1922, though Bartholow discovered it in 1872 in connection with aneurysm of the cavernous sinus. De Lapersonne and Cantonnet used this syndrome as a basis for classifying pituitary adenomata into two groups —those with chiasmal signs, and those showing evidence of pressure on the external wall of the cavernous sinus. That visual symptoms are absent in many cases of pituitary adenoma is, of course, well known; Cushing estimated that they were absent in 20%. German,[2] in a review of fifty cases in Cushing's series of 327 pituitary adenomata, found evidence of nerve involvement (exclusive of unequal pupils) in twenty-four; in ten of these the first indication of pituitary adenoma was given by symptoms of pressure on the ocular division of the fifth nerve. It appears, then, that in a certain proportion of cases the adenoma expands chiefly sideways, resulting in a clinical picture different from that usually thought to be characteristic.

THE PSYCHOLOGY OF QUISLINGISM

Most of us have been surprised by the influence that Hitler has exerted not only over his own people but over individuals in countries not his own—those who have been willing to collaborate with the Nazis even at the expense of their compatriots. The outstanding, and to ordinary eyes despicable, Quisling phenomenon is open to a variety of explanations—"Every man has his price," and "Nothing succeeds like success." There is, too, the stuff of which revolutionaries are sometimes made, such as spite, injured pride, bitter feelings of inferiority, and sensations of frustration and impotence in the face of the prevailing order. No doubt many of Hitler's converts are psychopaths like Hitler himself, but without the energy which makes him look like a genius. They are, in fact, in Henderson's terminology, "aggressive" but not "creative" psychopaths. Although these explanations are satisfactory up to a point, the suspicion that they do not explain everything is shown in the frequent references to the so-called hypnotic powers of Hitler, not only over his own people but over his political visitors. It is recorded of Napoleon that he had a similar effect in engendering fanatical and childlike self-abnegation in some people. Tolstoy,[1] with the intuitive veracity of the first-class novelist, records how an elderly warrior, his face flushed and his eyes gleaming, led his troop through a river, drowning forty of them in the process, for no better reason than that Napoleon was looking on. "Quos Deus vult perdere, prius dementat." There

[1] Tolstoy, *War and Peace*, Book 9, Chap. 2

is no sense in such a performance; it is rather a kind of masochism. Those who to this day collect relics of Napoleon, and in a sense worship his memory, are examples *in vitro* of the same kind of abasement. Devotion of such sort deserves examination for its unconscious roots. Dr. Ernest Jones, in a recent analysis of the psychology of Quislingism,[1] has described the various attitudes of those who approved of Nazism—the passive acceptance of the slum-dweller, who thought it a matter of indifference who governed; the denial of Hitler's aggressiveness by the escapist, who asserted there would be no war; the partial admission of Hitler's aggressiveness by the appeaser, who thought it could be bought off; and the man who thought the aggressiveness quite justifiable and even advisable. Jones ascribes all these attitudes in their various degrees up to the fully developed acquiescence and co-operation of the Quisling to the unconscious attitude toward the father. There is fear of him, and of one's own dangerous impulses towards him. The Quisling way is to identify might with right, and to say that because these dangerous impulses are strong they must also be good. At the same time they are denied within the subject himself and projected on to the father, who thereby becomes good as well as powerful and with whom the potential Quisling identifies himself. The attitude is psychologically homosexual. However hypothetical these speculations may be, they emphasize what is clearly important—namely, the part played by guilty feelings in inhibiting resistance to Hitler. German propaganda has in this respect taken a leaf out of the book of some religions. It has known too well how to play on the existence of a sense of sin in the people of Western civilization—a sense which Freudians believe to be based on the forgotten unconscious conflicts of infancy and childhood.

HOSPITAL WORK AN "ESSENTIAL SERVICE"

The reservation of occupations, generally with some age limit attached, and the scheduling of essential services must, of necessity, be a rough-and-ready matter, and a changeable one, too, as the war develops. But now that men of older ages are being called up many faults in the reservation schedule become evident. No doubt when the Essential Services (General Purposes) Order was framed there was a disposition to say that so far as hospitals were concerned it was sufficient that doctors and nurses were in reserved occupations, but that was to leave out of account the many other employees—engineers and electricians, mechanics and stokers, ward-maids and lift attendants—who are essential to the running of a hospital. An immense variety of skilled work, the result either of technical instruction or of long experience, goes into hospital management. The treasurer of St. Bartholomew's has drawn attention in the *Times* to the case of a hospital with 600 beds where a depleted staff of two stokers are working seven days a week to keep the steam and hot-water supplies going, without which the treatment of patients would be impossible, and one of these men is shortly to be called up and there is no one to take his place. The age of exemption of hospital secretaries and other whole-time paid officers has lately been raised, and the fears expressed in many quarters that hospitals might thus be left without adequate staff to administer them are only partially allayed by the latest Ministry of Health circular (No. 2390) on the subject. The Ministry states that all hospitals, if they have not already done so, should take steps immediately to obtain and train substitutes for any staff who are likely to be called up. Application may be made for deferment for a short period of any officer for whose replacement adequate arrangements have not been made, but before recommending deferment the Ministry will have to be satisfied that the duties cannot be performed by a woman or an older man of suitable attainments, or that efforts to obtain such a person have failed. As regards engineers, mechanics, stokers, etc., the circular points out that the age of reservation for such workers is lower in "protected" establishments than in "non-protected" ones, and the Ministry of Labour is prepared to consider applications for admission to the Register of Protected Establishments from hospitals employing at least one whole-time worker in any of these occupations with "dual age of reservation." So far so good, but in many instances it will not be so simple a matter, as the circular would appear to suggest, to train in a "short period" substitutes for the highly technical work of which a hospital secretary is in charge. Moreover, hospitals still remain unprotected against the competition of more highly paid employment. It is extraordinary that hospitals are not scheduled as an essential service, and safeguarded as much as an ambulance right of employees to leave their work. Hospitals are to-day in the front line; those in the cities are casualty clearing stations. They should be recognized as an essential service, and safeguarded as much as an ambulance service in the battle zone.

THE PHOENIX NUMBER

The letter of congratulation from a brother editor printed in our correspondence columns this week gives an opportunity to thank many readers and contributors for their kind messages and to say a few words by way of explanation. The "Notice to Readers" on page 755 of the *Journal* of May 17 was necessarily ambiguous, because one of the two events briefly chronicled was very recent and time has to elapse before explicit mention of such things may be made in public. The damage to B.M.A. House occurred during a heavy air raid on London in April. The dislocation of our printing arrangements by enemy action was some three weeks later. Nobody was hurt in these "incidents," but much valuable property was destroyed or severely damaged, and the second misfortune threatened to interrupt publication of the *Journal*. Prompt and effective action restored the printing front and established new lines of communication; so that the issue dated May 17, 1941, appeared without any delay, after being reset at great speed in a different type-face and passed for press under conditions imposing heavy strain upon all members of the Editorial, Advertisement, and Publishing Departments, and not least upon the indefatigable printers and proof-readers. Members of the Association who opened their *Journal* that week-end at the usual time may now be told that something not far short of a miracle had happened in the preceding four days, and that their thanks for this have to be spread over a large number of people who worked together for a common purpose. Fortunately, not many MSS. have been lost, and proofs of all matter standing in type were in safe keeping elsewhere when the enemy struck. Authors of articles or letters known to be missing have already supplied duplicate copies at our request.

The Royal Swedish Academy of Science has elected Sir Thomas Lewis, M.D., F.R.S., a Foreign Member in the Faculty of Medical Research.

Prof. J. A. Ryle, M.D., F.R.C.P., has been appointed Consultant Adviser in Medicine to the Minister of Health for the Emergency Hospital and Medical Services.

CHEST SURGERY IN WAR

This is one of a short series of articles based on lectures given at the British Postgraduate Medical School, Hammersmith

ANATOMY, PHYSIOLOGY, AND PATHOLOGY OF WOUNDS OF THE CHEST

BY

T. HOLMES SELLORS, D.M., M.Ch., F.R.C.S.

In injury to the chest, as also in the case of the head, it is not so much the damage to the container as the damage to the contents that matters. Actual damage to the enclosed viscera may have a profoundly adverse effect on the respiratory and circulatory systems, and to this may be added a series of secondary changes that result from the opening of the pleural cavity. These factors in themselves may be a grave menace to life, but even if they are successfully countered the question of the later development of infection has to be considered. Consequently a chest wound offers problems that are not found in many other parts of the body where the extent and effect of the destruction can be more or less estimated immediately.

Before entering into any discussion of anatomy and physiology it is well to have one precept in mind, and that is that the course and the effect of any missile after contact with the body are almost unpredictable. A well-known surgeon once stated that he was quite prepared to believe anyone's story about the behaviour of any missile on any human frame, and could add a few himself. The varying resistance of tissues, the angles of impact, and a whole host of factors make it imperative that no one should take the apparent track of a wound for granted when it comes to the question of diagnosis and treatment. Nor should it be forgotten that multiple injuries are only too common and that a small and apparently trivial wound may disastrously be overlooked in face of a more urgent and obvious lesion elsewhere.

Some Relevant Anatomical Points

In considering the gross anatomy of the chest there are some quite elementary points that are not perhaps always fully appreciated. The first point that strikes one when looking at the thoracic cage stripped of its coverings is its tapering or cone-shaped upper part. The squared appearance of the human torso depends on the shoulder girdle with its attached structures: in the region of the shoulders the actual thorax is deeply placed and is well covered by muscle layers, in contrast to the lower part, where ribs are easily palpable and the form of the thorax is quite apparent. The practical application of this feature lies in the fact that a missile traversing the upper part of the chest will pass through thick muscle layers which tend to close on the track and prevent communication of the pleural sac with the open air. On the other hand, penetration through the lower part of the chest is apt to leave the pleural cavity open and produce the dangerous form of "sucking" wound.

Among other points that may be emphasized is the height to which the diaphragm rises into the chest. This "doming" upwards of the muscle infringes considerably on the long axis of the thorax and leaves at the periphery the deep costo-phrenic sinus, which, it should be noted, is deeper behind than before. A penetrating wound of the lower chest will frequently puncture the diaphragm after injuring the lung fringe and produce varying lesions of the upper abdominal contents. The blood supply of the diaphragm is more extensive than might be supposed for such a thin sheet of muscle, and this should be remembered if incision through its fibres is practised.

A cross-section of the chest shows that the vertebral column projects far forward into the cavity, so that the distance between the sternum and the spine is relatively small (a matter of some 4 to 4½ inches), but on each side lies a large paravertebral gutter which accommodates much of the lung tissue. It is in these areas that fluid tends to accumulate in the pleural cavities, and that aspiration or drainage of the free pleural sac will be most effective.

The obliquity of the ribs is a feature that makes orientation and location in the chest much more difficult than if the thorax was a conveniently arranged system of transverse segments. A study of the normal antero-posterior radiograph illustrates the differences in level between the anterior ends of the ribs and their corresponding vertebrae. For example, the third costal cartilage lies in the same plane as the seventh thoracic vertebra, though clearly there will be individual variations according to whether the subject has a long flat chest or one of the barrel emphysematous type.

At this point it is not out of place to stress the importance of radiography, and indeed the absolute necessity for antero-posterior films in two planes, for the location of foreign bodies and other abnormalities. The ordinary antero-posterior view may reveal a foreign body lying close to the heart, but it requires a lateral film to show whether the abnormal shadow lies outside the chest or within it.

The anatomy of the ribs and intercostal spaces is important in view of the relationship of the associated vessels. The intercostal space is for all practical purposes a clear and safe area as regards the risk of haemorrhage—a feature that is taken advantage of in aspiration of the chest or when a trocar and cannula are inserted into the pleural cavity. The segmental vessels and nerve are under cover of the lower border of the corresponding rib, and will be injured only if the bone is broken. If it is uncertain whether active intrathoracic haemorrhage is coming from lung and/or chest wall the fact that ribs are intact exonerates the intercostal vessels, but if they are fractured arterial bleeding is a possibility.

Effects of Various Types of Missile

As has already been stated, the effect of a penetrating wound of the chest is variable, but there are certain general tendencies which may be described briefly. A *bullet* produces a small-punctured entry wound, and by virtue of its high velocity drills a clean hole with a minimum of surrounding tissue damage. If it passes through an intercostal space on both sides of the chest it does not make an unduly large exit wound. If, however, a rib is touched an explosive effect is produced and bone is shattered and driven onwards. This impact reduces the velocity and may turn the bullet sideways or even reverse it. The wound track is consequently more extensive and the damage to soft tissues correspondingly increased.

Fragments of bomb are jagged and acquire a tremendous spin, though their velocity is lower than that of a bullet. The effect on the tissues is extreme laceration even though the entry wound may in some instances be small. Pieces of cloth, dirt, and so on are apt to be carried in with the metal and are potential sources of infection, particularly as torn

tissue and blood constitute a fertile soil for bacterial propagation. As against this last statement I must admit that most of the fragments that I have removed from air-raid victims have proved sterile on culture. The lower velocity of this type of missile accounts for so many fragments being retained, and it is interesting to note how often their track ends subcutaneously. Presumably the elastic skin yields at what would otherwise have been the site of exit and does not break. I have seen the same effect inside the chest on several occasions when a fragment has punched a hole in the far side of the chest wall and recoiled within the meshes of the lung tissue, from which it was removed.

Crush injuries may be held to cover damage from falling masses of masonry, direct compression, and the like, and are often responsible for gross and fatal visceral damage without any penetrating wound. Ribs are commonly fractured, several adjacent ones giving way close to the posterior angle. If the bone also breaks anteriorly a whole section of chest wall becomes functionally loose and may be driven in—"stove-in chest"—and may act paradoxically on respiration. Within the chest, lung may be avulsed from its root, and rupture of the heart and great vessels be found.

The effects of "*blast*" have attained some prominence recently, but a full description and an explanation of the findings have not yet been achieved. It would appear, however, that numerous small haemorrhages and effusions occur throughout the alveolar and interstitial lung tissue. Free blood in the air tubes accounts for haemoptysis and also for patches of atelectasis. The distribution of the lesions is erratic, but it is probable that the peripheral areas are most affected, as might be expected when the direct violence of the explosive wave is inflicted on the chest wall. Sometimes it is in the lung fringes that the lesion is well demonstrated, and this may be explained by nipping of the soft tissue between the lower ribs and the diaphragm, which is driven up by the impact on the abdominal wall.

Physiological Considerations

The essential point of the normal physio-mechanics of the chest lies in the fact that two elastic lungs are pulling like evenly balanced springs on each side of the mediastinum. The lungs in turn are held out against the chest wall in a state of tension by the subatmospheric or "negative" pressure in the pleural sacs. If one pleural cavity is violated the underlying lung is released and recoils towards its point of fixation at the hilum. From this point a number of changes in the function of respiration take place.

With the formation of a pneumothorax the balance of the lung pull on the mediastinum is upset and the heart becomes drawn towards the unaffected side, whose tractive force is undisturbed. Inspiration, with general expansion of the chest wall, increases the tension of the sound lung and draws the mediastinum even more towards itself. The result is that with each act of respiration the mediastinum swings to-and-fro or "flutters." The effect of inspiration is to draw air into the unaffected lung, but as it does so it rushes past the bifurcation of the trachea and abstracts some gases out of the collapsed lung. It also means that this lung becomes reduced in size. With expiration the reverse effect occurs and some gases are forced into the collapsed lung, which thus moves paradoxically on respiration.

The movement of gases from lung to lung—the "Pendelluft" of Brauer—results in a steady increase in the CO_2 content and diminution of oxygen, with consequent inefficient and imperfect ventilation of the sound side. The sum of all these factors, if they occur to any marked extent, means that there is actual loss of ventilating surface by collapse of one lung, imperfect exchange of gases, and stimulation of the respiratory centre, besides the effects produced on the circulation by the to-and-fro movement of the heart and great vessels and interference with the venous return.

Puncture of the chest wall or lung may lead to an open pneumothorax, but if the opening is not valvular little harm will result. But, unfortunately, in traumatic surgery it often happens that a ragged external wound through the parietes constitutes a valve and admits more air than can be expelled. Air bubbling and frothing through blood at the skin wound indicates the "sucking" wound that is potentially so dangerous to the respiratory economy. Within the free pleural sac air accumulates steadily—a feature that is made worse by bouts of coughing, which are an almost inevitable concomitant of thoracic injury—and a state of intrathoracic pressure or tension is produced. *Tension pneumothorax* or pressure caused by a haemothorax is a common occurrence in thoracic surgery: the mediastinum is pushed over and encroaches on the ventilation capacity of the opposite lung.

For recognition of this phenomenon there is a physical sign that is often overlooked—namely, the position of the trachea in the neck. The tube is easily palpable in the suprasternal notch, and any deviation is readily apparent. The sign is valuable, since the apex beat and cardiac dullness are sometimes obscured by pleural fluid and are difficult to assess in a patient covered with dressings and bandages. The early recognition of a tension pneumothorax is of the utmost importance, since its neglect may lead to death from direct mechanical embarrassment, whereas its rapid relief could be obtained by putting a needle into the pleural cavity and letting the air escape.

It should also be remembered how tension phenomena can give rise to misleading signs and symptoms. The patient is cyanosed and distressed, and has a persistent cough. Where fluid is present the chest is dull, and on auscultation distant but definite bronchial breath sounds and rales are heard. The diagnosis of pneumonia may be made, but the audible breath sounds are conducted through fluid from a lung completely collapsed on to its root and the rales are transmitted from the opposite side, where the ineffective cough has been unable to expel mucus and secretions. There is no zone of partially collapsed lung to act as a damper between the air current in the bronchi and the chest wall to which the stethoscope is applied. To make an error in diagnosis as described may seem unnecessary, but in a very distressed and mutilated patient it is not always easy to practise the thorough and complete examination which would lead to the recognition of the true state of affairs. One can only emphasize the importance of remembering the possibility of "tension" occurring and deciding whether or not the trachea is in the midline.

Subcutaneous Emphysema

This is a common accompaniment of thoracic injury. The air usually comes from torn lung and is expelled through a breach in the chest wall, but does not escape adequately through an external skin wound even if one is present. The axilla and clavicular fossae demonstrate the typical crackling sensation, and in a severe case the whole head and neck may blow up, making the patient unrecognizable and the eyelids so swollen that he is unable to see. The condition is always more alarming than dangerous, and when it occurs in a crush injury without a surface wound it suggests damage to lung by broken rib fragments.

Haemothorax

The possible origins of blood in the pleural cavity are threefold: the intercostal or internal mammary vessels may be torn, pulmonary vessels may be ruptured, or the heart and great vessels may have been damaged. Clinically it is important to decide whether the bleeding is active or whether it has undergone spontaneous arrest. Section of an intercostal artery is likely to lead to uncontrolled haemorrhage and may therefore require urgent attention but pulmonary haemorrhage, unless rapidly fatal, tends to check itself. The reason for this latter lies in a balance between two groups of opposing factors. On the one hand, vessels in the lung have a wide lumen and the capacity of the pleural sac to receive blood is considerable but as against these features there are the potent influences of the relatively low pressure in the pulmonary circulation and the tendency of the lung to retract and so reduce the actual size of the wound in itself. To put it in another way, blood and air in the pleural sac form a pad which acts against the bleeding area. A haemothorax of several pints capacity is not incompatible with life, though prompt blood transfusions have certainly saved many lives

Blood in a haemothorax has one most unusual character in that it tends to remain fluid in a large number of cases. Infection and tissue laceration may produce massive clotting, but in many instances the effusion shows little if any clot and can be aspirated efficiently through a needle. I have on a number of occasions estimated the haemoglobin and fibrinogen content of both the circulating and the free pleural blood within a few hours of injury. The haemothorax fluid shows on an average a reduction of 35 to 50% haemoglobin and an almost complete absence of fibrinogen. The inference is that the movements of the heart and lungs have whipped up and defibrinated the blood as it wells into the pleural cavity. To account for the reduced haemoglobin figure it is suggested that the blood is diluted by a serous effusion poured out from the pleural endothelium in response to the irritation by blood The amount of clot, if any should be present, is so small that it seems improbable that a concentration of red cells in it would account for the low haemoglobin figure.

Massive Collapse

Massive collapse or pulmonary atelectasis is a feature that is quite often encountered, particularly with a crush type of injury. At first sight it may seem difficult to understand how an injury to one side of the chest can cause collapse on the opposite side, but the present conception of atelectasis as being basically caused by obstruction to a bronchus makes the explanation fairly straightforward Blood or mucus in the bronchial tree may not be removed effectively when the expulsive cough reflex is reduced by shock or pain. The foreign matter obstructs an air tube and as a result of this the gases distal to the block are rapidly absorbed into the blood stream. The alveoli become emptied and their walls fall together so that the affected area of lung is represented by a wedge of bronchi, vessels, and airless connective tissue. This elastic mass now affects the surrounding structures and draws them toward itself. The mediastinum is pulled over, the diaphragm elevated, and the chest wall retracted, and the adjacent lung develops compensatory emphysema. If the atelectatic area fails to re-expand, as it does in some cases, the pull of the elastic fibres is finally directed on the only structures which are left for it to affect—the enclosed bronchial elements. In the early stages the cartilaginous bronchial walls tend to resist the external traction, but the continued centrifugal pull finally results in their stretching and becoming dilated. In short, in any case of persistent collapse bronchiectasis will inevitably follow, and it is a question of later secondary infection which determines whether or not the classical signs of infective bronchiectasis will develop.

Pathological Changes

The pathological changes in traumatized lung are very much what would be expected, laceration and haematoma formation being the principal features. The extensive blood supply of the lung accounts for the fact that many badly torn fragments remain viable though their liability to later infection is considerable. A haematoma of the lung presents as a tense firm swelling of rubber-like consistence and of a purple or violet colour, with the visceral pleura stretched almost to breaking-point over its surface. Extravasation into alveoli produces a condition of consolidation which is demonstrated clinically by stained sputum, which later becomes purulent as the condition resolves. The detailed effects of infection on the lungs and pleura will not be discussed here, though their role in the subsequent fate of the patient is clearly of the utmost importance.

Distant Reflex Complications of Chest Injuries

These complications are often considerable though some of the effects may be attributed to damage inflicted elsewhere in the body. There are, however, certain features associated with what appears to be chest injury alone, and of these retention of urine is the most common and most easily remedied. Acute dilatation of the stomach is apt to be overlooked in its early stages and, if untreated, may cause considerable and serious trouble. Among these abdominal complications may also be mentioned "blast," in which multiple and diffuse haemorrhages in the mesentery and under the bowel peritoneum may result in a fatal peritonitis: I have encountered two such cases accompanying a penetrating wound of the chest.

DANGEROUS DRUGS IN INSTITUTIONS

The Home Office has issued a new Order, to be known as the Dangerous Drugs (Approved Institutions) No. 25 Order (1941), approving certain institutions where persons in charge of laboratories may be in possession of and supply drugs and/or preparations to which the Dangerous Drugs Act, 1920, applies. The institutions named in Schedule A are as follows:

All Universities (including Colleges of Universities) of Great Britain.

The University College, Nottingham.

The University College, Southampton.

The University College of the South West of England, Exeter.

The University College, Glasgow (The Glasgow Royal Technical College).

All Medical Schools recognized by any of the licensing bodies specified in Schedule A of the Medical Act, 1858, as amended by any subsequent Act.

Royal College of Surgeons of England.

The National Institute of Medical Research.

The Royal Veterinary College, London.

The Royal (Dick) Veterinary College, Edinburgh.

The Glasgow Veterinary College.

The School of Pharmacy of the Pharmaceutical Society of Great Britain.

Institute of Chemistry of Great Britain and Ireland.

Approval under the Order will remain in force only so long as the Home Secretary is satisfied that the following conditions are complied with:

The person in charge of the laboratory: (1) shall keep all supplies of the drugs and preparations under lock and key and in his own charge, and shall only issue to persons working in the laboratory such quantities as shall be immediately required in the course of research or instruction; and (2) shall keep records of all amounts of drugs and preparations purchased by him in the forms prescribed in the First Schedule to the Raw Opium Regulations, 1937, and in the Second Schedule to the Dangerous Drugs Regulations, 1937, and shall furnish to the Secretary of State whenever required a copy of these records together with a statement of the amounts of each of the drugs and preparations remaining in his possession.

NATIONAL FLOUR FOR BREAD

M.R.C. SPECIFICATIONS

The following is the text of the Medical Research Council's second memorandum on bread, which sets out the specifications for nationa' flour.

The Accessory Food Factors Committee of the Lister Institute and the Medical Research Council, in a memorandum issued in the summer of 1940, recommended the adoption for bread of a flour of 80 to 85% extraction of the wheat, in the following terms:

> " Flour for the bread of the people should contain the germ of the wheat grain, as much as possible of the aleuron layer, and the finer portions of the bran. Instead of flour consisting of about 70% of the wheat grain, as it does at present, the percentage extracted should be at least 80 to 85%."

Since this recommendation was made the Ministry of Food has decided to make generally available to the public bread baked from flour of 85% extraction. In the original memorandum the nutritional considerations on which the recommendation was based were set out. It now seems desirable to restate them, incorporating the results of further research and defining more exactly the character of the particular 85% extraction flour recommended by the committee.

Special Nutritive Properties of the Flour Selected

The degree of extraction was fixed at 85% in order to secure a flour which should contain: (a) As much as possible of the B vitamins, including riboflavin and nicotinic acid and especially of vitamin B_1 present in the whole wheat. (b) As much protein as possible, including a high proportion of that situated in the outer layers of the grain. This protein is known to possess a higher nutritive value than that contained in white flour. (c) As little bran as possible, so that there should be no risk of loss of nutritive value due to presence of much indigestible material. Wartime diets already contain much vegetable food, with relatively large amounts of roughage; it is undesirable to increase this further.

Production of Flour of 85% Extraction

Flour of 85% extraction can in practice be obtained by two general methods: (i) by rearrangement of the milling machinery to produce a flour containing 85% of the wheat, or (ii) by addition to the white flour (73% extraction), obtained in the ordinary milling processes, of combinations of the other fractions of the wheat.

The consideration which has influenced the final choice of the flour to be adopted has been the need to combine two qualities: first, the best nutritive value; and, secondly, the production of a loaf as little removed as possible in colour, texture, and flavour from that of ordinary white bread. Two flours, prepared respectively by the above methods (i) and (ii), were chosen as possessing equal nutritive value, the first, however, being preferable as fulfilling the second condition most perfectly. Flour (i) was selected as the best for the following reasons:

(a) Of all flours obtained at the same level of extraction by different methods from the same grist, it had the highest vitamin B_1 content, and in this respect closely approached that usually accepted for wholemeal bread.

(b) It had the lowest fibre content compared with other flours extracted at this level from the same grist.

(c) Of all the breads tested, baked from 85% flour, it yielded the one which resembled white bread most closely in flavour and texture.

(d) The colour of the bread was pale brown and was not unattractive.

(e) On technical and on aesthetic grounds the loaf baked from it was considered excellent.

Definitions Proposed for the Selected Flours

Flour (i).—This straight-run flour may be defined as a flour containing 85% by weight of the clean wheat, in which is included (a) the maximum amount of the germ and of the aleuron layer, and (b) the minimum of the pericarp, as shown by its low fibre content.

Flour (ii).—May be defined as (a) containing 85% of the weight of the clean wheat grain, in which is included all the white flour, all the reduction roll tails, mill finish and purifier tails, and sufficient fine bran to bring the amount of the mixture up to 85% of the clean wheat; (b) containing 85% of the clean wheat and excluding 15% consisting of the bran and pollards.

Analyses of samples of flours (i) and (ii) are set out in the table below, with those of white flour of 73% extraction and of wholemeal flour, all four materials being derived from the same grist (water content being 15%).

Flour	Fibre %	Ash %	Protein %	Vitamin B_1 I.U. per gm. (Thiochrome Method)	Calcium mg./100 gm.	Phosphorus mg./100 gm.	
						Total	As Phytic Acid
i (85%)	0.60	0.90	11.4	1.2	27	203	123
ii (85%)	0.85	0.94	11.5	1.15	27	211	123
White (73%) ..	0 to 0.20	0.46	10.6	0.35	15	101	33
Wholemeal (100%)	1.8	1.51	11.9	1.4	36	343	236

Samples of flours (i) and (ii), obtained from the same grist, were found to be similar in content of protein, ash, and vitamin B_1, which in both cases was over 1 I.U. per gramme (thiochrome method). The fibre content of both flours was less than 0.9%, that of flour (i) being lower than that of flour (ii) by about 20%. The lower the fibre content the better is the flour and the more efficient is the milling.

Keeping Properties.—No exact evidence is as yet available regarding the keeping properties of the particular types of flour selected, but from the experience gained of other brown and wholemeal flours there is little doubt that this flour of 85% extraction could be kept in good state under reasonable conditions of storage for four to six weeks or longer.

Recommendation I.—The Accessory Food Factors Committee at its meeting on January 23, 1941, recommended that a flour of 85% extraction, similar to flour (i), should be adopted. Since modification of ordinary milling machinery would be required for production of flour (i), and this would take time, it was further recommended that a flour of 85% extraction, similar to flour (ii), should be adopted in the meantime, as this could be produced without any delay. The flour should not contain less than 1 I.U. of vitamin B_1 per gramme, and the fibre should be less than 0.9% (assuming a water content of 15%).

Addition of Salts to Flour

Calcium Salts.—It is known that the intake of calcium salts in the diets of this country, especially among the poorer classes, is often below the minimum accepted by nutrition experts as necessary for satisfactory growth of bones and teeth in growing children and for maintenance of the bones in adults. The addition of calcium salts to bread was recommended in the previous memorandum issued by the Medical Research Council. It is now possible to add details concerning the amounts required. Wholemeal bread and bread made from flour of 85% extraction contain more calcium than white bread and also more phosphorus. A large proportion of the phosphorus, however, is present in a combination (phytic acid) in which it is not directly available to the organism and at the same time diminishes the availability of the calcium present in the bread and in the rest of the diet. Recent tests made on human subjects for the Medical Research Council have shown that to maintain a sufficient supply of calcium salts for health more calcium salts must be added to the diet. The most convenient way to do this is to add calcium carbonate to the wheat flour used for bread. As a result of the above test on human subjects it has been calculated that additions are needed of 65 mg. of calcium per 100 grammes of white flour (7 oz. of $CaCO_3$ as creta praeparata B.P. per 280 lb. sack) and of 130 mg. of calcium per 100 grammes of flour of 85% extraction (14 oz. of $CaCO_3$ per sack). In the case of the 85% extraction flour the extra 7 oz. per sack is required to neutralize the effect of the extra phytic acid contained in flour of this degree of extraction. It has long been a practice in baking to add similar amounts of substances known as " improvers " (e.g., acid calcium phosphate 12 oz. per sack, or up to 1½ lb. per sack in case of certain self-raising flours at present on the market). The addition of the recommended amounts of calcium carbonate to flour has no effect on the vitamin B_1 content of the flour or on its baking properties.

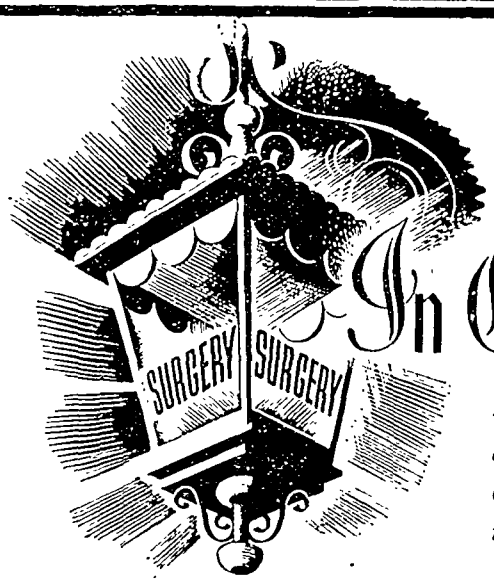
Recommendation II.—It is recommended that calcium carbonate (as creta praeparata B.P.) should be added to the wheat flour from which white bread is made in the proportions of 7 oz. per sack (280 lb.) of white flour and of 14 oz. per sack of 85% extraction flour.

Iron Salts.—The desirability of adding iron in some form to flour has been considered, the reason being that anaemia due to insufficient iron in the diet is common in this country and could easily and cheaply be prevented by the administration of simple ferrous salts. A study of the available data on this subject has, however, led to the conclusion that the presence of added iron salts in flour might cause destruction of some of the other nutrients present. It is therefore not recommended that any such additions be made until further knowledge on this point is available.

'NOVALGIN'

TRADE MARK BRAND OF NYNALGIN

Eliminates



PAIN

'NOVALGIN' is a pyrazolon derivative available for oral and parenteral administration. It is well tolerated and effective in many different types of pain.

'NOVALGIN' HAS A CONSIDERABLY STRONGER ANALGESIC ACTION THAN THE SALICYLATES

BAYER

BAYER PRODUCTS LIMITED, AFRICA HOUSE, KINGSWAY, LONDON, W.C.2

In General Practice

—cases are encountered daily which call for the prescription of one or other of the following British-made drugs:

★ DAGENAN—M & B 693 ★
For pneumococcal, gonococcal and meningococcal infections.

★ THIAZAMIDE
For cases which prove intolerant of "M & B 693."

★ SOLUSEPTASINE
For parenteral administration in streptococcal infections.

★ SONERYL
For insomnia.

★ GARDENAL
For epilepsy.

★ MYOCRISIN
For rheumatoid arthritis.

★ THEOGARDENAL
For high blood pressure.

★ PROSEPTASINE
For oral administration in mild streptococcal infections.

★ SOLUSEPTASINE Ointment
For topical application in bacterial skin infections.

★ SONALGIN
For insomnia associated with pain.

★ RUTONAL
For epilepsy.

★ S.V.C.
For Trichomonal vaginitis.

"*Improvers.*"—The addition of certain "improvers" to bread baked from flour of high extraction facilitates the work of the baker and results in a more attractive loaf. Such evidence as is available does not justify at this stage the prohibition of their use in the baking industry, and the question has therefore been left open.

THE FUTURE OF PHARMACOLOGY

DIXON MEMORIAL LECTURE

The third W. E. Dixon Memorial Lecture was delivered before the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on May 13 by Prof. J. A. GUNN, who took as his subject "The Future of Pharmacology." Sir William Willcox presided.

Prof. Gunn began with a reference to W. E. Dixon, whose researches, he said, were characterized by a wide range rather than deep exploration in a limited field. Dixon was interested in the scope and function of pharmacology, its place in the medical curriculum, and the facilities afforded to it. In one of his last public lectures, in Capetown in 1929, he expressed dissatisfaction with the position of pharmacology, and claimed that it should be a separate discipline in both research and teaching in medical schools.

Was pharmacology still, as Dixon believed, the most neglected branch of medicine? Pharmacological research might be said to have begun, in sufficient volume to matter, about 1870, at a time when the medicinal use of the substances in the *materia medica* was based upon tradition and empiricism. It was right that pharmacological inquiry should devote itself to the examination of the credentials of this heritage of drugs. Chairs of pharmacology and laboratories were established. The search for new remedies was exciting and gave pharmacology a new standing. Many new plants had been investigated, but the most significant change had been the far greater volume of research on new artificial compounds. The preliminary qualitative investigation of the pharmacological action of a plant might be made with simple apparatus and without any high degree of skill; but when it came to the modern search for new remedies, which usually entailed the preparation of a large number of compounds, the conditions were different. The synthetic pharmacologist could never guarantee that any of the new compounds would have new pharmacological properties or therapeutic value, and thus, although it seemed an obvious solution of the quest for new remedies to secure co-operation between the academic pharmacologist and the academic chemist, in fact this had seldom materialized. It might be suggested that the pharmacological laboratory should possess its own chemical annex and synthesize its own compounds, but this would mean duplication of departments, at which universities might look askance. It was not sufficiently realized that the search for new remedies and new synthetic compounds involved chemical synthesis on a large scale. The field must be extensive even if it need not be ploughed deeply. For a university to take up work of this kind was not very practical. The value of the work was apt to be assessed simply by its success in producing a new remedy.

General and Particular Study in Pharmacology

Prof. Gunn next turned to the relations of pharmacology and physiology. Physiology concerned itself with the normal function of living organisms or tissues; pharmacology with the modification of function produced by chemical agents. The methods used in both were the same, and the subjects were so closely allied that it might seem unnecessary or unwise to separate them; but the primary aims were so different that it was well for the two to be regarded as separate disciplines. For convenience and with a certain amount of justification, pharmacological investigation of substances could be divided into two stages: the study of the general pharmacological action indicating which particular organs were acted upon, and the more intensive and qualitative analysis of substances which appeared to show any kind of therapeutic interest. This distinction between general and particular pharmacology was important. There were certain drawbacks to general pharmacology. It meant a wide range of experiment rather than an intensive study of one system. For general pharmacology the pharmacist required a wide training in physiological technique. The primary survey was sometimes despised as superficial, but the superficial analysis was essential, and not necessarily easier than the analysis of what lay beneath. The worker in general pharmacology had to go from one type of experiment to another, relying on his experience and judgment to decide how far it was economical to pursue the experiment in depth. He must have a competent knowledge of physiology, and use methods which, if not the most elaborate, were at least not obsolete. At the end of his labour he might find that the compound which he had investigated showed no kind of physiological interest nor promised any therapeutic value—that is to say, a value superior to that of the known remedies, and as the number of remedies increased it was becoming more difficult to find one which was better than those in use.

On the other hand, research in particular pharmacology offered certain obvious advantages. If a worker confined himself to the action of one particular system of drugs, he required only one set of apparatus and he could limit his reading; as a consequence, pharmacological research workers usually showed a preference for particular research. This resulted in early specialization, which was a mistake. Beginners were apt to be influenced by the glamour of some great physiologist who had pursued investigation in depth, forgetting that he started with a wide range of technique, and only proceeded to deep investigation when he recognized that the conditions were ripe for it. Again, specialized pharmacology soon lost touch with therapeutics.

The Commercial Pharmacological Laboratory

A development which was beginning in Dixon's time but had acquired increasing momentum since was the establishment of commercial pharmacological laboratories. This was a significant development whereby the future of academic laboratories would probably be affected. It began in Germany, but other countries, especially Switzerland, the United States, and Great Britain, followed suit, and now there were in many countries pharmacological laboratories attached to drug factories which for staff, accommodation, equipment, and finance equalled or excelled the resources of the universities. Their primary object was to discover new remedies by the sale of which the manufacturer hoped to recoup himself. Many of the firms, however, engaged in research of a purely scientific kind, and some of these laboratories were doing important work in that direction. When one looked back to Dixon's complaint that practically all the new remedies came from abroad and that British pharmacology was much behind other countries, he thought this was becoming less true so far as commercial laboratories were concerned. There were possible drawbacks to the introduction of drugs from the commercial side, but the therapeutic value of a drug was not in the least influenced by the motives which inspired its discovery. He mentioned the advantages of commercial laboratories—their larger staff of chemists, their ability to get the necessary products from some other branch of the manufacture, their possession of plant which made them able to produce on a larger scale than the laboratories attached to universities. It was significant that most of the newer remedies had come in the first instance from commercial laboratories.

Finally the lecturer turned to the position of pharmacology in the curriculum and the desirability of a special examination in the subject. The scope of pharmacology was sufficiently wide and its outlook sufficiently idealistic for it to be regarded as a separate discipline. Unless this was done and proper arrangements made, it was unlikely that medical students would be adequately instructed in the kinds and uses of drugs.

The first campaign directed wholly against gonorrhœa to be held in a major city in the United States was recently launched by medical and health groups in Rochester, New York. Among the agencies taking part in the campaign are the County Medical Society, the State Department of Health, the Tuberculosis and Health Association, the Rochester Pharmaceutical Association, and the University of Rochester Medical School.

DESTRUCTION AT THE ROYAL COLLEGE OF SURGEONS

Disaster due to enemy action has befallen the priceless collections of the Royal College of Surgeons of England. During a recent raid a heavy bomb fell directly on the Museum of the College in Portugal Street and fire completed the destruction. Although the Lincoln's Inn Fields façade is still erect and seems to have suffered nothing but broken windows, a scene of heartbreaking desolation awaits one in the entrance hall. The famous lecture theatre is a charred ruin, its pilasters just recognizable. The main block of the Library remains, with books still on the shelves. The principal treasures of the Library had been taken away before the end of last year after some damage in an earlier raid, and the same is true of the equipment of the Bernhard Baron research laboratories on the uppermost floor. But the Museum, the greatest treasure of the College, containing possessions such as no national collection could boast, is a heap of rubble amid which the bones of some amphibian or other indestructible curiosity grotesquely project. Many of the specimens had been placed in tunnels below the building, but the fall of the heavy girders of the main structure broke the thick floor and enabled the fire to sweep the basements. Until the work of excavation has proceeded further no exact assessment of the loss can be made, especially as the College records and catalogues, which are always in a state of revision, were also destroyed.

Loss of the Hunterian Collection

Hunter's world-famous collection, which formed the basis of the Museum, may be said to have disappeared. The fraction which remains only serves to emphasize the greatness of the loss. Of the collections illustrating human anatomy not more than twenty specimens have been saved. Large numbers of specimens of human osteology, including anthropological material, have perished. Of 5,200 mammalian specimens illustrating comparative osteology, perhaps twenty or thirty survive, but hardly any of the 3,000 avian specimens or the large amount of amphibian, reptilian, and aquatic material have escaped destruction. Rooms IV and V, built in the middle of the last century, and housing physiological specimens and comparative anatomy, were blasted away. A loss most grievous is the anthropoid room. Specimens brought from the other side of the globe by Sir Joseph Banks and Captain Cook have also gone. The fine collection of primitive Tasmanian skulls and of Australian skulls and skeletons, the original Gibraltar fossil cranium, and the mummy room, containing one of the best collections of mummified material in existence, are no more. The great bulk of the teratological collection (monsters and malformations), numbering over 200, the collection of calculi and concretions, over 500, the collection of trephined skulls, the Onodi collection, and the Cheatle collection of temporal bones are destroyed. The collection of invertebrates, numbering over 2,000, is a total loss. The entire Army Medical War Collection of pathological and other specimens has disappeared, with the exception of Henry Tonks's pictures and one or two specimens which had been moved away after the building was previously blasted. The room containing historical instruments no longer exists; a few of the instruments have been salvaged, but after the treatment to which they have been subjected they are not likely to be of much value or interest. The instruments used by Lister himself are still in a case in the hall. The artificial Roman leg, the old stethoscopes, the illustrations of the evolution of instruments have all gone, and so, it is believed, have Jenner's medicine chest and his silver lancet, and certainly Hunter's furniture.

Specimens that have been Saved

Turning to the brighter side of the picture, Rooms I and II, built in 1888, still stand, although roofless, and the human specimens they contain are almost intact. The Negus laryngological collection has been saved, except for one large wax specimen, and the collection of the Odontological Section of the Royal Society of Medicine, containing about 5,000 specimens, of which the College was the custodian, has also been preserved. Of the anthropological material, a good many of the Nubian specimens still exist, along with the Mount Carmel fossil material. Paget's classical skeletons have been preserved, also the specimens illustrating the comparative anatomy of the brain. The histological section, containing some 12,000 specimens around a nucleus of 200 of Hunter's, is still in existence, and the salvage includes Hunter's great auk, the dodo, and the moa, also specimens illustrating Hunter's experiments on growth, which were in the basement under sandbags. One cares less about the survival of some of the College curiosities, such as the skeleton of the consort of Richard Cœur de Lion and others whose authenticity is by no means beyond doubt, and the Sicilian dwarf and the Irish giant have not much scientific interest. The College statue of Hunter, which was a prized possession, had been bricked up, and has been preserved uninjured—at least the brick erection still stands foursquare amid the surrounding ruins.

An appeal will be made in due course to the members of the medical profession to contribute specimens to a new collection, but the treasures of historical interest can never be replaced. The patient acquisition and labour of a couple of centuries are brought to nothing in a night by an act of such purposeless vandalism as makes one aghast even amid the repeated insanities of war. The act seems to negative that upward thrust of evolution which the Museum so magnificently exemplified. Questions may be asked later why the policy of dispersing the exhibits was not adopted, but in the meanwhile we can only extend our sympathy to the President and Council of the College, and not less to the conservators and curators past and present, to whom the collection was a part of their very lives.

Nova et Vetera

SIR D'ARCY POWER'S LIBRARY

Before the sad news of Sir D'Arcy Power's death reached them many people had heard with regret that Messrs. Sotheby were to disperse the large and valuable collection of medical books which one of the most honoured Nestors of the profession amassed with taste and discernment over the greater part of his long lifetime. The sale opens on Monday, June 9, at 11 a.m.

William Harvey is well represented: it is true there is no copy of the most desirable of all his works, the *De Motu Cordis*, in its original edition, but there are two copies of the first edition in English (1653, Francis Leach for Richard Lowndes). The *De Generatione* is here in the 1651 Amsterdam edition, as well as in the first English edition (1653, James Young for Octavian Pulleyn) and in the Hague edition of 1680. There are two copies of R. Banister's *Treatise of One Hundred and Thirteene Diseases of the Eyes* (1622, Felix Kyngston for Thomas Mann); also an earlier (1586) *Briefe Treatise touching the preservation of the eie sight, by Walter Bayley*, Physician to Queen Elizabeth; this is an especially desirable copy, as it is inscribed by the author to his "lovinge frynde mr John Pophame," who was Attorney-General and treasurer of the Middle Temple. John Browne's *Adenochoiradelogia* is subtitled "an Anatomick-Chirurgical Treatise of Glandules and Strumaes," 1684; it is represented by the first edition and also by another of the same year. With the latter is catalogued Beckett's *Free and Impartial Enquiry into the Antiquity and Efficacy of Touching for the Cure of the King's Evil*, 1722. J. Bulwer's *Philocophus*, or *The Deafe and Dumbe Mans Friend*, 1648, is being offered with some others as one lot. Older than these are J. Goeurot's *Regiment of Life*, black letter, 1550; Alexis of Piedmont's *Secretes*, translated by W. Warde, 1568; Francis Arceus's *Most Excellent and Compendious Method of Curing Woundes*, 1588, with a picture of a surgical boot of surprisingly modern appearance. Andrew Borde's *Breviarie of Health* is listed in three editions—1575, 1587, and 1598. William Clowes is represented by his *Briefe and Necessarie Treatise*, 1585, about syphilis and its treatment by inunction; Paulus of Aegineta by his *Opus Divinum* of 1532. There is also a second edition of W. Bullein's *Bulwarke of Defence Against all Sicknesse*, 1579, which is noteworthy as it has a contemporary calf binding. The *Regimen Sanitatis Salerni* and others of that school are present in more than a score of editions and commentaries, the most desirable, perhaps, being

that of 1480, and an Italian MS. in Latin, also of the fifteenth century; Thomas Paynell's translation into English, 1557, is among those offered. T. Gale's *Workes of Chirurgerie*, 1586, and Roesslin's *Byrth of Mankind*, edited by Thomas Raynold, 1552, have their title pages reproduced in the catalogue. T. Vicary's *Englishe-mans Treasure*, 1586, has bound in with it William Turner's *Rare treasor of the English Bathes*, gathered and set forth by William Bremer, black letter. Another very desirable volume is the first edition of Bartholomew Traheron's translation into English of John Vigo's *Most Excellent Workes of Chirurgerye*, 1543, "wyth the Kynges moste gratious privilege for seven yeares" Mention should also be made of the *Orders and Ordinances for the better Government of the Hospitall of Bartholomew the Lesse*, 1580; and of the *Statutes of 32 Henry VIII*, black letter, 1540, containing "an Act concerning the privileges of phisicions, and an act concernyng Barbours and Surgeons to be of one companie." There are other rare medical books in the collection, which contains also many books not of medical interest and will take a day and a half to pass completely through the hands of the auctioneers *Ekru, fugaces . . .*

Correspondence

Rehabilitation of the Injured

SIR,—The correspondence in your columns following my article on rehabilitation of the injured (April 5) has raised several points to which I feel prompted to reply.

Both Mr. Griffiths and Mr. Butterworth rightly stress the importance of correct psychological approach, and the former raises the question as to whether the methods I described of measuring and recording efficiency in affected muscle groups might not, by focusing the patient's attention on his injured part, induce an introspective state of mind unfavourable to recovery. I have never found any such effect in normally balanced patients—in fact they react in the opposite direction by deriving encouragement and initiative from the evidence of improvement shown in their muscle efficiency charts. In some cases this improvement has been so gradual that the patient would otherwise have been unable to appreciate it from week to week, and these charts have then fulfilled a most useful purpose by preventing those doubts and fears which so often appear in the late stages of serious injury and destroy the patient's will to recover. It is the absence of improvement, either imagined or real, and not the measurement of it, that depresses the patient and causes him to develop psychoneurotic tendencies about his disability. There is another type of case in which the psychoneurosis is a thing apart, quite independent of any physical disability that may or may not exist. These cases are not affected either one way or the other by purely physical methods of treatment and are not suitable for the type of rehabilitation centre I described.

Dame Georgiana Buller raises two very interesting points. She advocates a more comprehensive use of the term "rehabilitation" to include vocational training on the grounds that this is "economic rehabilitation," whereas what we as surgeons are concerned with is physical rehabilitation. There is also a third variety—namely, psychological rehabilitation. It may be desirable to have a general term to cover all three processes, but it is equally desirable to be able to refer to each of them in quite specific terms. Psychological rehabilitation is the province of the psychiatrist; physical rehabilitation is the province of the traumatic surgeon; and vocational training is a matter primarily for workers outside the medical profession.

Dame Georgiana Buller would favour the creation of institutions where all these activities can be carried out under one roof, but I am convinced that this would be a mistaken policy. No seriously injured miner would ever go back to work in a pit if he were presented with any alternative method of earning a living, especially if, as in the example quoted by Dame Georgiana Buller, this also increased his earning power. If his failure to recover held out the prospect of being transferred to another section of the centre where he could be taught to make a living in more pleasant and easy paths, the recovery rate would fall to zero. Very few people become miners from choice, and I imagine the same applies to other industries in which the work is arduous and dangerous and in which there are periodic slumps which affect the workman's security of employment.

The whole success of vocational training depends not simply on learning a new job but on being able to get it afterwards. Otherwise vocational training ceases to be "economic rehabilitation." The best way to ensure that there is always a sufficient number of these jobs to go round is to see to it that there are as few cripples as possible in need of vocational training. This can best be done, as Mr. Watson-Jones so clearly points out, by providing the facilities for complete physical rehabilitation wherever fractures are treated—and the time to do it is now.—I am, etc.,

Mansfield, Notts, May 22. E. A. NICOLL.

Treatment of Peripheral Nerve Injuries

SIR,—In a recent discussion on peripheral nerve injuries at a meeting of the Orthopaedic Section of the Royal Society of Medicine many interesting points were brought up, and among them was the highly satisfactory announcement that in England at least such cases are segregated for treatment in special hospitals. Surely a similar segregation should also be carried out in Scotland. Rowley Bristow said it was necessary for the older surgeons to cast their minds back for some twenty years in order that some elementary mistakes might be avoided. As things are at present much of that experience is not being made use of, as many of the cases are subjected to operation in hospitals which have not the equipment to deal with them. The results are seen in the Ministry of Pensions hospitals. Doubtless few of the hospitals are supplied with a faradic battery or a condenser discharge apparatus suitable for use at operation, and so valuable information is not available at an important stage. The finer muscular movements and sensations are difficult enough to achieve in median and ulnar lesions without adding to these difficulties by delay and doubtful treatment.

In the last war a very thorough training was considered necessary before a young surgeon did any major orthopaedic surgery At Bangour, the Edinburgh hospital, there was the opportunity of the teaching of Sir Harold Stiles, and many long weary hours were spent assisting a splendid team of American surgeons before the personal conduct of an operation was permitted. It is not suggested that such a training is necessary, but if segregation cannot be achieved in Scotland then it is necessary that in the interests of the patient and therefore of the country some form of supervision should be instituted to ensure a uniformly high standard of work.

I believe, however, that all nerve cases should be admitted to orthopaedic hospitals near their own homes before any treatment is carried out—in fact, as soon as diagnosed. I say *any* treatment, because even bad splintage of a few weeks' duration may irreparably damage joints such as the metacarpophalangeal joints of the hand. Following the period of in-patient treatment an adequate after-care scheme will be necessary in which the cases are followed by those concerned in their hospital treatment with physiotherapeutic measures and occupational therapy where possible.

It was an interesting commentary on the vulnerability of peripheral nerves in air raids as compared with war wounds to hear from one of the surgical directors that there were only 0.7% of nerve injuries over a considerable number of casualties in a recent air raid. If this percentage should prove to be correct, then the evolution of a scheme for segregation of cases should present few difficulties.—I am, etc.,

Edinburgh, May 14. WALTER MERCER.

Stirrup Pump Solution: A Warning

SIR,—It has come to my knowledge that solutions of zinc chloride are being sold to the public for attacking incendiary bombs through the stirrup hand-pump. I am informed that these solutions contain about 70% of zinc chloride. It would seem right to issue a warning concerning the use of such solutions, especially in confined spaces. Zinc chloride in the above strength is a corrosive poison, and if some of it got into the eye it would be extremely painful; it would produce temporary blindness, thus immediately incapacitating the operator of the pump; and even if effectual treatment was applied at once permanent damage would be likely to result. I am further informed that when these solutions are brought into contact with burning magnesium, fumes of hydrochloric acid and zinc chloride are evolved. If such fumes are inhaled there may be serious effects in the respiratory passages.

Finally, if such solutions come into contact with the skin and are not washed off they may cause skin lesions.

I am not in a position to express any opinion as to whether such solutions are greatly superior to water in dealing with incendiaries and the fires caused thereby, but I do express the opinion that unless this be so, the possible dangers involved from their use are such that it would appear to be most undesirable to permit the public to have unrestricted use of them.—I am, etc.,

London, W.2, May 19. G. ROCHE LYNCH.

Coventry Revisited

SIR,—After an interval of five months Coventry was again subjected to heavy air raids in April of this year, and the question might be asked, Did the A.R.P. services do better work because of what was learned during the previous devastating raid?

In the raid of November, 1940, the main difficulty of doing any sort of first-aid treatment arose from the fact that the supply of running water, gas, and electric light to the posts failed, and the substitutes for these essential services were not immediately available. Obviously it was necessary to remedy this. After the experience of the November raid a large tank of water, frequently changed, was kept at the post where I am stationed, and it was hoped that the supply thus kept ready would suffice for any one night. In April of this year, when the wardens' whistles were heard, denoting that incendiaries had fallen (a good signal to get busy), the nurse ordered all hot-water bottles to be filled with very hot water, instruments to be boiled, dressings arranged, beds made up, etc. Our preparations were complete before the first casualty arrived, and shortly afterwards the gas supply failed. Lamps were also lit, so that, if the electric light had failed, there would have been little mental shock to the casualties and no pause in the work of dealing with them.

We had, I think, learned something about the better disposal of casualties within the post. Obviously badly wounded and shocked cases were screened off and placed close to radiators, but a first-aid post is not a hospital, and screens are few. We were, however, fortunate in getting two excellent cases early in the evening—an old man and his daughter. They had been buried by debris. They were filthy dirty, but their only complaint was that they both had lost their false teeth. We put them at the side of the ward, facing the entrance, and gave them tea, and until they went to sleep they welcomed every new casualty with a broad edentulous grin, which seemed to say: "Come and join the party. You'll be all right now."

One thing we have still not learned. We have not learned how to remove clothes quickly and painlessly. It is no easy matter to remove a heavy leather overcoat from a man who complains of, say, a pain in his arm. It seems hardly justifiable, and not easy, to cut to pieces a heavy leather coat, possibly to find that the only injury is a mere contusion.—I am, etc.,

Coventry, May 10. NOËL R. HOLMES.

Obscure Nervous Effects of Air Raids

SIR,—The correspondence that has followed upon my letter (April 12, p. 573) stimulates me to venture on some further remarks on the above subject. For to the best of my belief the explanations offered by Dr. H. Crichton-Miller (April 26, p. 647) and Dr. Clifford Allen (May 10, p. 727) do not by any means cover all the cases that I had in mind. They appear to be of the view that the cases of stupor and extreme distress, which I mentioned in my letter, are predominantly or entirely due to physical effects of air raids. I have a certain amount of reason to question this.

Actual studies in a London district and in a coast town, extending over some three months in each case, have shown that depressed morale is not always directly associated with the amount of bombs. There is a tendency for those who are living immediately around an incident to stay put, wherever houses are habitable, better than those living further away from an incident or incidents. There is a tendency for those who have *nearly* been hit to feel that they have had their turn, whereas those who have only seen or heard of others nearly hit feel all the more insecure and that "it's our turn next." This type of reaction can be measured by studies of evacuation, especially of adults from undamaged houses. We hope in the near future to publish a very detailed study of this sort which we have made, where we have related every bomb to the corresponding households, found out how the households have split up or stayed put, attempted to measure the effects on habits, opinions, and morale of those who have stayed through the numerous bombardments.

All this suggests to me—and this is confirmed by a good deal of other research that we (Mass-Observation) have done in the morale field—that it is often those not so directly or physically affected by air raids who are most upset by them. And there do not seem to be as yet any data to justify generalizations such as those made by Dr. Crichton-Miller. I feel that his letter was rather in line with the general medical attitude that stimulated me in the first place to draw attention to this matter. There seems to be a distinct, perhaps unconscious, tendency to gloss over the serious psychological effects that air raids have on people, and to insist that the neurotic effects are negligible.

I have spent practically the whole of the past eight months with a unit of investigators in all the "blitztowns" except Belfast. Apart altogether from the cases of stupor and lethargy I mentioned in my previous letter, I have seen many cases of distress, shock, mild hysteria, and several instances of personal panic. The great majority of people behave with their normal calm and common sense, of course. But no one who has spent any time objectively studying behaviour in the "blitztowns" and getting right in among the mass of the people could shut their eyes—however hard they try—to the very considerable effect that continuous raiding has on people's nervous system, irrespective altogether of the physical impacts. I suspect that the most upsetting factor is *uncertainty*, the intensive insecurity of living in a "blitztown." First, you never know what night the raid is going to come. Secondly, you never know which 'plane noise or other noise is the noise which may mean your end. Too many generalizations have been made from a purely London experience. London is a different story; it is so huge and anonymous. I know from personal experience that it is ten times more unpleasant to be blitzed in a place the size of Coventry or Bristol, where every bomb is personal and every piece of damage is a disaster to one's own town, instead of this great agglomeration of towns which is called London. In London, moreover, those with nervous tendencies have had an invaluable line of retreat, lacking in practically every other city. They have been able to bury themselves underground in the Tubes. The Tubes have provided a safety valve for those who might otherwise have behaved "badly."

There is one other point. The unplanned evacuation which has marked the blitz situation is in itself largely a nervous reaction and one with serious consequences. But the very fact of evacuation relieves the tensions and anxieties which are felt of people stay put. If bombs fall on or near villages to which people already blitzed in a town have evacuated themselves, or if some other highly disturbing circumstances arise, then these people, who have already fallen back as far as they can along the line of physical retreat, may be forced along a further line of psychological retreat. And I think this explains some of the cases I mentioned in my first letter. As I said then, and repeat again, I am only an amateur on this matter. But I do want to insist that there *may* be a genuine problem here, and that if I am right in saying that there is a problem, then it is one which is being neglected. Unfortunately, there is little sign in the correspondence on the subject that anyone intends to do anything else but go on neglecting it. Perhaps the statements on the perfection of our own morale have lulled the medical profession into complacency on this subject? But I hope not.—I am, etc.,

London, W.11, May 14. TOM HARRISSON.

Gas Masks and CO

SIR,—In the article on the diagnosis and treatment of gas casualties in the issue of May 10, should not the first sentence of the concluding paragraph, which reads at present—"The gas-mask, if properly adjusted and in time, gives full protection to the lungs and eyes against all these gases"—have added to it the words, "except carbon-monoxide"?—I am, etc.,

Oxford, May 14. A. G. SANDERS.

Treatment of Burns

SIR,—I heartily agree with Dr. John Gordon (May 17, p. 763) that first-aid posts should use only innocuous substances such as sod. bic. compresses. As medical officer in charge of a first-aid post in my district I have instructed the sister that all cases, no matter how severe the burn should be treated with sod. bic.

The procedure adopted is to clean the burn as best we can (without an anaesthetic). We prick all blisters and wash away all debris (it is surprising how dirty the burns are that we have to treat at first-aid posts); we use an ordinary eye irrigator for this purpose, and again use a sod. bic. solution. A compress of sod. bic. (two to three layers of ordinary white gauze) is then applied and lightly bandaged. A mild sedative such as sod. phenobarb. 1/2 grain is usually given in first and second degree burns (I find there is usually some degree of shock present). In the worst burns with severe shock I give morphine 1/4 grain. All our cases, no matter how trivial are referred to hospital for further treatment.

At one time we used only lot. ac. tannic. or "tannafax" but I found that the personnel (all first-aid workers) were not quite experienced in this form of treatment, and the sod. bic. compress is now the only method of treatment adopted.—I am, etc.,

LOUIS SHELDON,
Medical Officer in Charge, First-aid Post.

Willesden, May 16.

Diphtheria Immunization

SIR,—Surely enough evidence has been collected by now to come to the conclusion that the Schick test is for all practical purposes a reliable guide to a person's susceptibility to clinical diphtheria. I think Dr. Tudor Lewis has elucidated this point well in his recent excellent book on *Diphtheria Immunization*. Some public bodies do not seem to have realized this yet. Only quite recently I had a letter from my boy's public school asking me whether I would agree for my boy, aged 17, to be immunized against diphtheria by two inoculations. There was no mention whatsoever of the Schick test. Actually my boy was inoculated against diphtheria at the age of 5, and was Schick-negative four months afterwards. I took the trouble to Schick-test him again now and found that he was negative. It would have been a waste of time and material to have had him inoculated again now.

I have come to the conclusion that it is worth while to perform a primary Schick test on all children over 5 years of age. I always take the precaution of repeating the Schick test in four months' time on all children under 10 years of age who happen to be Schick-negative in the first place. Having had an opportunity of immunizing a large number of children since January last, I have kept to one definite method and hope to publish my results as soon as I have completed a sufficient number. This may help the medical profession to come to one general standard for diphtheria immunization.—I am, etc.,

H. W. SWANN,
Medical Officer for Diphtheria Immunization for the Boroughs of Hackney and Islington.

May 19.

Sarcoidosis

SIR,—Dr. G. E. Lewis has described an interesting new case of uveo-parotitis (April 12, p. 552), but his conclusions call for comment. The case is described as one of Adie's syndrome, which it may well be, but there is no description of myotonic pupil reactions; the patient may, of course, have been an atypical example of the syndrome, or in an atypical phase, but there may be another explanation for the pupil changes and tendon areflexia. Were the pupils fixed as a result of a previous attack of irido-cyclitis? In uveo-parotitis the formation of synechiae is very common and no reference to their presence or absence is made. Other unequivocal evidence of involvement of the *central* nervous system is lacking (the areflexia may have been of peripheral origin) and the claim for "visceralization" is too strong. Dr. Lewis describes the development of uveo-parotitis, with the usual histological changes, and quite rightly states that this syndrome is now generally recognized as part of a much more diffuse disorder, for which the term "sarcoidosis" is as good as any other at present. But to claim that no case of this condition ("sarcoidosis of Boeck") showing neurological signs or symptoms has previously been reported is a little surprising. Before the relationship between uveo-parotitis and Schaumann's disease (Schaumann was the first to show that Boeck's sarcoid of the skin was part of a widespread disorder) was realized, it was well known that facial palsy was one of the common signs of the former and that widespread polyneuritis, of varying degree, was not uncommon. Undoubtedly examples of involvement of the central nervous system have been admittedly rare, but Waldenstrom (*Acta med. Scand.*, 1937, 91, 53) reported a remarkable case in which typical uveo-parotitis was complicated by a gross cerebral and possibly spinal disorder; and there have been others, probably including some of those described as "encephalitis lethargica associated with parotitis."

As our knowledge of the clinical picture of sarcoidosis increases it is becoming evident that practically every tissue in the body may be involved, and there is no reason why the brain and spinal cord should be exceptions. On the other hand, I do not think Dr. Lewis's case is sufficiently strong to form the basis of a claim that sarcoidosis bears any relationship to Adie's syndrome.—I am, etc.,

Leeds, April 26. HUGH G. GARLAND.

Undergraduate Teaching in the Municipal Hospitals

SIR,—Mr. Somerville Hastings in his article on post-war medical education in London (May 3, p. 678) has rightly called attention to the opportunities for undergraduate teaching which exist in the municipal hospitals.

At the time when we were students these hospitals were used, as he states, solely for courses in "fevers" and a few attendances at a mental hospital. I feel sure that there would have been insuperable difficulties against extending the teaching at that time, and that the same situation continued until after the last war. But between 1919 and 1939 municipal hospitals improved out of all recognition both in equipment and in the standard of the personnel, with a resulting advance in the clinical work of the hospitals. Mr. Somerville Hastings dismisses in three lines the undergraduate teaching in municipal hospitals in 1939, and this certainly underestimates the position and the progress which was being made. My own hospital, St. Thomas's, is very fortunate in the municipal hospitals in the vicinity, but other teaching hospitals also were taking similar steps. For some time, perhaps not more than two or three years before the present war, we had been rapidly establishing contact with the municipal hospitals, and we were invariably met more than half-way, both by the staff of the hospitals and by Sir Frederick Menzies and Dr. Daley at County Hall. Members of the personnel of municipal hospitals have been placed on our hospital committees, and teaching facilities in these hospitals and arrangements for further developments were advancing steadily. By no means all the teaching was undertaken by the staff of St. Thomas's Hospital. A clinical round in a municipal hospital taken by the superintendent or a senior medical officer would attract, voluntarily, fifty or sixty students. This was partly a tribute to the teaching powers of the personnel, but it was also due to a realization by the students that they would see a type of clinical material which could not be sufficiently represented in a teaching hospital, a point to which Mr. Somerville Hastings rightly calls attention. But I would not entirely agree with him in comparing this material to the ordinary everyday cases of general practice. Unfortunately a knowledge of such everyday cases can be acquired only in general practice, and the Committee on Education of the B.M.A. failed to find any practical method by which this knowledge could be gained before qualification.

This evolution, which was proceeding throughout London, and no doubt elsewhere, with increasing momentum, was interrupted by the revolutionary episode of war. A large number of medical students were suddenly thrown into municipal hospitals that were scarcely prepared for them and had had little voice in the arrangements. Some temporary dyspepsia and anorexia may have resulted, but close contact has been established, and we may be sure that the advantages will outweigh the disadvantages. Nevertheless, even if nothing were learnt from this upheaval, the evolution which was already in progress before the war would undoubtedly continue. The municipal hospitals and the teaching hospitals both realize the

benefit which would accrue from such liaison, and have been moving together with friendship and good will.

Much more remains to be done, but I am sure that Mr. Somerville Hastings will welcome the information that the movement had already progressed so far.—I am, etc.,

London, W.1, May 15. H. LETHEBY TIDY.

American Doctors for Britain

SIR,—I am much interested in this subject now before the profession from an experience during the last war, when I occupied the position of chairman of the Recruiting Medical Boards for Cumberland at Carlisle, where thousands of men were examined. I have no hesitation in expressing the view that the present arrangements are superior to 1914-18, and if they were effected to the full there should be little need for the emergency call for 1,000 American doctors at this time. But it is not so, for although a large number of available British doctors have already registered in the ordinary course comparatively few have been posted to date.

During the recruiting period of the last war applications for posts on Medical Boards were received from qualified men hailing from several other countries, and a number were accepted, but temperamental variation and habitude barred the way to good co-operation and harmony; acute friction resulted with consequent resignations, with the result that the whole clinical system extant suffered acutely. I would like to be informed why so many English doctors, quite dispensable for service, under the age of 30 have not been called up and are enjoying seclusion in their own practices. I am satisfied that if the committees in authority for absorbing all the available medical man-power were exhaustively conducted, there would be little need for the emergency call to the Western Hemisphere, initiating an anomalous position. During the last war medical man-power was reduced to an absolute minimum, and only a fraction of the medical community was left to carry on medical practices—in fact, a dangerous position was reached. At the present time, however, the general health of the nation is good, and the vital intelligence of the people is such that this should be maintained for the remainder of the war.—I am, etc.,

C. W. GRAHAM, J.P.,
Ex-President of the Border Counties
Silloth, May 13. Branch, B.M.A.

Medical Man-power

SIR,—I should like to make the following observations on the subject of medical man-power.

1. Doctors of military age are being reserved on account of large panel practices.

2. Doctors whose names are being forwarded by Local Medical War Committees are not being called up. This excludes members of the E.M.S., of teaching staffs, medical officers of health, etc., who are automatically referred to the Central Medical War Committee.

3. As chairman, Local Medical War Committee, City Area, and of Holloway No. 5 Medical Board, I am in touch with many men from widely separated areas. I am told the same story in each case. Hundreds of medical men in London are facing bankruptcy because they have nothing to do.

4. Final-year students are replacing doctors.

5. A thousand U.S.A. doctors and 1,400 aliens are ready to relieve pressing need.

6. One must assume that the central body is *au fait* with conditions in London.

7. There is, in fact, a reserve of British medical man-power available in London waiting to be used.—I am, etc.,

Hampstead, May 9. JAMES FETTES.

SIR,—From letters to the *Journal* and from its advertisement columns it is obvious that the country's medical services are in an unsatisfactory state, which urgently calls for improvement. On the one hand, we have doctors in the raided evacuation areas suffering severely from insufficient work; on the other, doctors in reception areas clamouring for assistance rarely forthcoming.

Is the explanation that the former, often elderly men and women with considerable liabilities, feel that they, should they leave their district, have no protection for the nucleus to which the practice of each has been reduced, or is there some other explanation, possibly also financial? One may be willing in the present emergency to take what offers, but these assistants will many of them be doctors of considerable experience, and their services have, or should have, a much greater financial value than those of the peacetime newly qualified assistant.

A State Medical Service may be inevitable, but in that case it is important that nothing should be done now to encourage the development of a too cheap service. I must admit, however, that the salaries offered in many cases are by no means low.

The matter is urgent. Can anyone offer a reasonable, helpful suggestion? The introduction of American doctors may have its merits, but should not be necessary.—I am, etc.,

London, W.8, May 19. HAROLD H. SANGUINETTI.

SIR,—In the *Journal* of May 10 are letters under the headings "Medical Man-power" and "Overburdened Doctors in Reception Areas," but I have so far failed to see any reference to the unfortunate position of medical men in what might be called voluntary evacuation areas such as Brighton. Our patients of substance have long since left for safer areas. Our male and female panel patients are either called up for the Services or are being drafted into factory work or are seeking domestic service in hotels and houses in reception areas. This reduces one's income to a dangerous level. Add to this the fact that one's partner, a man of considerable experience, is called up to the R.A.M.C. as a lieutenant, instead of as a captain, with commensurate pay to his rank and knowledge, and things are far from rosy! Whereas doctors in the reception areas are truly overworked, and presumably are deriving a welcome increase in remuneration whether they desire more work or not.

Before calling on doctors from America surely use should be made of those of us who are not overworked. After all, charity should begin at home. Why cannot the profession sponsor a pool of medical men from distressed areas and money from reception areas, so that we may all live under more favourable circumstances with less monetary worry?—I am, etc.,

Brighton, May 18. F. HUGO STUTTAFORD.

Overburdened Doctors in Reception Areas

SIR,—Dr. Sophia Graham in a letter (May 10, p. 727) writes concerning the difficulty of obtaining help for overburdened doctors in reception areas. Though compulsorily out of the fray myself, I hope it may not be presumption to state that a great difficulty is the natural reluctance of senior men to accept positions usually held by junior men, and the natural reluctance of the general practitioner to invite a senior to accept such a position where the senior's professional skill, or in some cases social prestige, will have but little outlet or appreciation. General practice (without increase in insurance capitation fee) does not admit of payment of large salaries for assistance, but ought salaries, position, or the diversion of specialist services for a time to be a difficulty? The B.M.A. has, by its fund for temporarily distressed doctors, presumably a list of doctors willing to take work without strict regard to their professional earnings and position in the past, and there should be just as much honour in accepting altered professional conditions as in the fighting Services, where there are thousands of brilliant men who have had to forgo their normal careers and sacrifice position and earnings.—I am, etc.,

Tavistock, Devon, May 19. FRANK BRYAN.

Medical Certification

SIR,—As a factory medical officer it has been my experience that the lessons of the last war have not been appreciated by the medical profession. It was then common knowledge to factory managements that medical certification, especially in T.N.T. conditions, was not of a very high standard. The following two experiences of mine might illustrate what is happening to-day.

Certificates were sent in to the factory stating that an employee was suffering from bronchial asthma due to T.N.T. poisoning. When I saw the employee at the factory surgery I considered that she was suffering from pulmonary tuberculosis,

and referred her to the tuberculosis clinic, who confirmed this, and stated that they had found tubercle bacilli in her sputum. From the other angle, I had a certificate from a doctor to say that a patient of his who had been medically rejected was perfectly fit and healthy, although he stated she had a swelling of the thyroid. This woman was suffering from thyrotoxicosis, and I consider such a condition should be under medical care, and anyone suffering from it is certainly not a fit subject for work with T.N.T. This her doctor disputed.

Diagnosis of T.N.T. poisoning by the factory medical officer is not an easy matter. Our employees whom we suspect are suffering from T.N.T. poisoning have a very extensive examination, which includes blood-pressure reading, Webster urine test, blood count, and examination of stained blood films over and above a physical examination.

It is the earnest wish of factory medical officers that full co-operation between the patient's own doctor and the factory should be established, and it is my desire in this letter to be constructive and helpful. If the panel practitioners are in difficulties regarding their patients whom they presume to be suffering from T.N.T. poisoning, we will do our utmost to assist them, if they communicate with us.—I am etc

May 14. J. H WATSON

SIR,—I was interested to read Dr. J. B. Wrathall Rowe's letter (May 10, p. 732) in which he expresses his views as a factory medical officer on the question of the acceptability of many certificates of incapacity. Recently this subject gained singular importance when a magistrate refused to accept their validity. That the medical certificate should thus fall below the status of a legal document is a matter for concern.

The task of the practitioner is not an easy one when dealing with these applications. He is unable wholly to disregard statements by patients, and in many cases must grant a certificate while lacking proof of their veracity. For example, a man may come to the evening surgery requesting such a document on the grounds that he was incapacitated that day by diarrhoea. Many patients do not appreciate the responsibility incurred by the doctor in granting a certificate, particularly in insurance and contract practice. It is beyond their comprehension that their doctor, for whose services they have contributed weekly payments, should hesitate to sign his name to any statement requested of them by employer, employment exchange, or school authority, etc. Certificates which were "ludicrous in the extreme" may have been issued as a means of avoiding prolonged argument during a busy surgery.

Under war conditions a number of new types of medical certificates are now demanded by Government Departments and local authorities. As a result of these certificates and coupons, a complex appears to have arisen which is rapidly leading to abuse. Some retailers of foodstuffs seek to solve the difficulty of distributing scarce commodities by requesting a medical certificate. In consequence of all this patients are tending to regard the surgery as an additional coupon office.

To end such abuses the medical certificate must be issued under stricter control. The patient must also be made to realize that all certificates cannot be demanded as a right. One way would be to charge a nominal fee in the form of a legal stamp, already customary with legal documents. A postage stamp could, for instance, be affixed to existing printed forms. Other certificates, including that of incapacity, could be supplied in printed book form with embossed Inland Revenue stamps, a practice already familiarly used. The annual yield to the Treasury from such a duty would be considerable, and the present time seems most appropriate for its introduction. As a result of the legalized formality of such an arrangement, the patient would tend to appreciate something of the nature of his request. The cost to be incurred would perhaps minimize unnecessary applications. A practitioner's refusal to accept payment for an unworthy application would be better understood than by a lengthy explanation. In some areas it is already the practice to charge a fee when issuing certificates, and it would be an advantage if a fixed charge could be agreed upon which would include the stamp duty.—I am, etc.,

May 20. R. H. GREIG.

SIR,—In the past few days I have signed certificates as follows: (1) for corsets; (2) to exempt fire watchers suffering from disease; (3) for extra milk; (4) to exempt from military service men passed as Grade I suffering from tuberculosis and Hodgkin's disease; (5) for one of two special types of gas-mask—only one of which is actually available. Surely it is time the B.M.A. took a hand in abolishing this certificate mania.

Apparently in the case of the extra milk the certificate must be signed every month; presumably to the official medical mind tuberculosis is a disease of a month's (or less) duration. Coupled with the recent warning of the G.M.C., and the fact that the nature of the person's illness has to be disclosed to clerks and dairymen, it is evident that the practitioner's word is not to be trusted, as he is warned by the judge—namely, the disciplinary body—and has to explain himself to the jury—the clerks and dairymen. I feel sure I am expressing the feelings of my colleagues, and hope you will publish this in your columns, which are our only mouthpiece.—I am, etc.,

Cottingham, E. Yorks, May 14. R. D. B. WRIGHT.

The Phoenix Number

SIR,—May I offer my congratulations on the production of last week's *British Medical Journal*, dated May 17, and its publication at the usual time? I wondered how you would do it, and I still do not know—it is a great effort.—I am, etc.

W. K. FITCH,
Editor, the *Pharmaceutical Journal*.

London, W.C.1 May 22.

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Captain FRANK ROBERT OLIVER HAYWARD died suddenly at Gutting Grange on May 19. He received his medical education at Guy's Hospital and qualified M.R.C.S., L.R.C.P. in 1932. He had held the post of house-physician at St. Bartholomew's Hospital, Rochester and before the war was in practice at Chelmsford where he was honorary anaesthetist to the local hospital.

Prisoner of War

Major Alastair Gordon Donald Whyte, M.B.E.

DEATHS IN THE SERVICES

Major-General ALEXANDER ARTHUR SUTTON, C.B., D.S.O., late R.A.M.C., died at Tunbridge Wells on May 12, aged 79. He was born on November 30, 1861, took the L.R.C.P.Ed. and L.R.F.P.S.G. in 1884, an entered the Army as surgeon in 1885. He became colonel in 1915, major-general in 1917, and retired in 1920. He served in the campaign in Sierra Leone in 1898-9, when he was severely wounded (West African medal with clasp); in the South African War in 1899-1902, taking part in operations in the Orange Free State, including the actions of Paardeberg (wounded), Poplar Grove, Karnee Siding, Vet River, and Zand River; and in operations in the Transvaal including actions at Pretoria, Johannesburg, and Diamond Hill, was mentioned in dispatches in 1901, and received the Queen's medal with four clasps, the King's medal with two clasps, and the D.S.O. He also served in the war of 1914-18, when he was twice mentioned in dispatches in 1916 and received the C.B. He also received the Serbian Order of St. Sava (Third Class) for services at Salonika in 1917.

Lieutenant-Colonel MICHAEL DAVID AHERN, O.B.E., R.A.M.C. (ret.), died in Dublin on May 10, aged 64. He was born on September 6, 1876, the elder son of the late Mr. T. Ahern, J.P., of Glanmire, County Cork, was educated at Queen's College, Cork, and at the Cecilia Street Hospital, Dublin, and took the Scottish triple qualification in 1902. Entering the R.A.M.C. as lieutenant in 1904, he became lieutenant-colonel in 1920, and retired in 1931. He served in the war of 1914-18 and received the O.B.E.

The Federal Department of Health in Mexico has been reorganized under the new administration with Dr. Victor Fernandez Manero chief of the Federal Department of Health, Dr. Mario Quinones Secretary-General, and Luis Bobadilla in charge of the office.

Obituary

SIR D'ARCY POWER, K.B.E., F.R.C.S., F.S.A.

Surgeon and Medical Historian

As briefly announced in our last issue, Sir D'Arcy Power, surgeon, medical historian, biographer, and librarian, died on May 18 at his home at Northwood, Middlesex, to which he had lately moved after many years in Chandos Street, Cavendish Square. He was spared the news, made public a day or two after his death, of the damage caused by enemy action to the Royal College of Surgeons and its possessions which he had served so devotedly for over half a century. No English surgeon has ever been held in more affectionate regard in his own and other countries.

D'Arcy Power was born in London in 1855, the son of Henry Power, who died in 1911 at the age of 82, after serving St. Bartholomew's as ophthalmic surgeon for most of his working life. In a tribute to his father D'Arcy Power once wrote that his versatility, friendliness, and courtesy showed his Southern Irish ancestry, and his dogged perseverance was derived from a Dutch and a Quaker strain. Certainly the same qualities, however derived, were characteristic of the son. He was educated at St. Marylebone and All Souls' Grammar School and later at Merchant Taylors' in the City, where, at 17, he was awarded the prize as the boy best fitted for a merchant's office. This fate was averted, and he matriculated at Oxford, from New College, in 1874, and obtained an open exhibition at Exeter College in 1877. He then became demonstrator to the University, lecturer on physiology at Magdalen, gained a first-class in the honours school of natural science in 1878, and proceeded M.A. in 1881.

In 1878 he entered St. Bartholomew's, with which he was to identify himself as one of its most beloved and devoted sons. In a lecture given in later life, after recounting the jealousies and rivalries of the older Bart's, he described how when he came to the hospital as a young man of 23 he found himself among a "most intelligent body," who at once appointed him a teacher, invited him to their Christmas dinner, and told him they had given him the opportunity of winning his spurs should he be so inclined. The whole staff of the hospital, which then numbered twenty-eight, were his good friends. The teaching post to which he was assigned was that of assistant demonstrator of physiology. In 1882, the year of his qualification, he became house-surgeon to Sir William Savory. He once recalled that at the time he was assisting Savory in the theatre a single pair of forceps was alone provided to arrest bleeding even in so large an operation as amputation of the thigh.

His entrance into consulting practice may be said to have dated from 1885-6 when he was appointed surgeon to the Metropolitan Dispensary and assistant surgeon to the Victoria Hospital for Children. He retained the post of curator to the museum at St. Bartholomew's, and from 1889 to 1901 he was demonstrator of practical and of operative surgery at that hospital, and of surgical pathology from 1901 to 1904. Like John Hunter, he took an interest in comparative medicine, and from 1890 to 1903 he lectured on histology and physiology at the Royal Veterinary College. In 1898 he was elected assistant surgeon at St. Bartholomew's on the resignation of Sir Thomas Smith, and he became full surgeon in 1904 on the resignation of John Langton. This position he held until 1920, when he was made consulting surgeon. He had the reputation of being a good all-round surgeon who showed at his best in an emergency operation.

His election to the Fellowship of the Royal College of Surgeons had taken place in 1883, the year after he qualified. Six years later he had become an examiner in physiology for the Fellowship, a position he held for thirteen years. In 1896-7 he was Hunterian professor of surgery and pathology. He became a member of the College Council, at the same time as the late Lord Moynihan, in 1912, was re-elected in 1920, and made vice-president in 1921, and again in 1922. In 1919 he was Bradshaw Lecturer, in the following year Vicary Lecturer, and in 1925 Hunterian Orator. He represented the College on many important bodies—the Imperial Cancer Research Fund, the University of Bristol, and Queen Victoria's Jubilee Institute for Nurses among others—and he was the College delegate at the International Historical Congress in London in 1913, the centenary celebrations of the Académie de Médecine de Paris in 1920, and the opening of the Royal Australasian College of Surgeons at Melbourne in 1935. Of the many offices he held at the College, one, that of honorary librarian, was created for him. No one had greater knowledge of the treasures of the library or spent more time in its precincts. He was also at various times examiner for the Universities of Cambridge and Durham, Queen's University, Belfast, and the National University of Ireland.

But it is as a writer that Sir D'Arcy Power has the largest of his many claims to remembrance. His first published writing appeared in 1877. It was entitled "On the Albuminous Substances which occur in Urine in Albuminuria," and was written with Sir Lauder Brunton for St. Bartholomew's Hospital Reports. His first book, a manual for the physiological laboratory, written with Dr. Vincent Harris, was published within the next five years. His first clinical paper, notes on a case of congenital locomotor ataxia, from the wards of Dr. Samuel Gee, bears the date 1882. His first venture into the history of medicine was his admirable edition of South's "Memorials of the Craft of Surgery" (1886), prepared at the request of Sir James Paget, who wrote an introduction. This was followed by a long series of unsigned historical articles in the *British Medical Journal*. He "kept his head above water," to use his own phrase, by "devilling" for Ernest Hart, the then Editor, whom he described as a master in the art of extracting "copy" in the form of articles and abstracts at a moment's notice. Hart's encouragement, and not less his criticism, which was sometimes caustic, served the literary apprentice in good stead. Since those early days we are glad to have published under "Nova et Vetera" or other title many an attractive and scholarly note from his pen, not to mention a large number of articles on clinical subjects and many reviews of books.

In 1931, on his seventy-fifth birthday, and on the initiative of the Osler Club, Sir D'Arcy was presented by subscribers with a volume of his "Selected Writings." To that volume is appended a short-title bibliography of his contributions to literature; it contains more than 600 entries. Many of these are short "lives" of medical and other worthies in the *Dictionary of National Biography*, to which his first contribution was made in 1893. In addition to biographies he wrote numerous articles on historical subjects connected with medicine, more especially the medicine of the sixteenth to the eighteenth century in England. In all this research and writing he was far from being the mere specialized antiquarian. He had a keen sense for the quaint and amusing, and a turn of his pen would give a bygone incident or practice its full human quality. The patience and skill which he displayed in illuminating the byways of medical history are illustrated in his presidential address to the Medical Society of London on "John Ward and his Diary." John Ward was a medically minded parson of Stratford-on-Avon in the seventeenth century, and the address was the outcome of four years' work off and on, in transcribing sixteen small books of crabbed writing. In these out-of-the-way fields Sir D'Arcy Power was just as eager and inexhaustible as when he was on the more open ground of the work of Harvey and of Hunter, the history of hospitals, and the craft of surgery. One of his most valuable pieces of medical biography, carried out with the help of his colleagues, W. G. Spencer and G. E. Gask, was his revision of the biographical notices of the Fellows of the Royal College of Surgeons from 1843, when the diploma was first instituted. These had been drawn up with great patience by Victor Plarr, librarian of the College for many years, but never published in his lifetime. The work was brought up to date by D'Arcy Power and prepared for publication in 1930.

But it must not be supposed that he employed his writing only on historical subjects. He wrote extensively on cancer and on the surgery of the abdomen. Thus the bibliography above mentioned includes 77 articles on abdominal surgery, 39 on malignant diseases, 23 on orthopaedics, 12 on intussusception. Scarcely a number of the *British Journal of Surgery* appeared from 1913 onwards without some contribution from him. In 1895 he wrote his "Surgical Diseases of Children," and in 1915 an Oxford primer on "Wounds in War," and he was co-author of a "Handbook of Surgical Pathology" and a work on "Diseases of Joints."

No man was better known in the medical society life of London. He had been president of the Medical Society, the Harveian Society, and the Sections of History of Medicine and of Comparative Medicine of the Royal Society of Medicine; he was on the council of the Pathological Society and the British Orthopaedics Society. He had become a member of the British Medical Association in 1892, and was a sectional officer at various Annual Meetings and president of the Section of Surgery in 1926. He was corresponding member of several foreign societies, and one of the secretaries of the National Committee for the four International Congresses of Medicine which were held in various capitals between 1900 and 1909. He was vice-president of the London meeting of the International Society of the History of Medicine in 1921 and honorary president of the Geneva meeting in 1925. In 1938 he was honorary president of the International Society of Surgery. In 1924 he went to America, was for two months visiting surgeon-in-chief of the Peter Brigham Bent Hospital, Boston, and was made an honorary Fellow of the American Surgical Association at Baltimore, where he delivered an address on "How the Tradition of British Surgery came to America," with some information about the earliest English teachers to cross the Atlantic in the late eighteenth and early nineteenth centuries. In 1930 a small work of his, "Medicine in the British Isles," was published in New York.

Many societies outside medicine claimed his interest. He was the founder of the Samuel Pepys Club; he wrote a delightful medical history of Mr. and Mrs. Pepys, discovered who performed lithotomy on Samuel, and even prescribed glasses which would have enabled him to continue his diary. He was a prominent figure in the Society of Antiquaries and the Bibliographical Society, and was great among the Freemasons, founder of the Rahere Lodge at St Bartholomew's. The building of the new Freemasons' Hospital at Hammersmith was a project near to his heart. The writer of this notice remembers being conducted round that building by Sir D'Arcy, who, in spite of his lameness and of entreaties not so to fatigue himself, insisted on accompanying his visitor to every floor and out on to the roof.

Many other activities in this full life can only be mentioned—his work for many years on behalf of the Royal Medical Benevolent Fund, as visitor for King Edward's Hospital Fund for London, as chairman of Pinewood Sanitorium, as member for eighteen years of the Faculty of Medicine of London University, as member of the Board of Management of the Metropolitan Convalescent Institution. Even eighty-five years seems too short to crowd in all this activity.

At the outbreak of the last war he became lieutenant-colonel R.A.M.C. (T.) and was officer in charge of the First London General Hospital (T.F.), and later on of its Surgical Division. He was also consulting surgeon to the military hospital at Bromley and surgeon to the Officers' Hospital at Fishmongers' Hall in the City. It was for this relatively brief service in military uniform, not for his lifetime in the library, that he received his knighthood in 1919.

In 1882 he married Eleanor, daughter of G. H. Fosbroke, M.R.C.S. of Yorkshire, who died in 1923. One of his sons was killed in the second battle of Ypres in 1915; the other, Group Captain D'Arcy Power, is in the R.A.F. Medical Service.

Long as is the catalogue of his achievements and distinctions and manifold as are his contributions to the lore of medicine, the outstanding thing which those who knew him will recall will be his unassuming friendliness, his cheery disposition, and his real beauty of character.

A note on some outstanding items in Sir D'Arcy Power's personal library, which he had instructed Messrs. Sotheby to sell next month, will be found at page 830 of this issue of the *Journal*.

[The portrait reproduced is by Lafayette.]

W. H. GIBSON, M.B., AND L. F. SKINNIDER, M.B.

We regret to announce the deaths, through enemy action, of two Paisley practitioners, Dr William Hamilton Gibson and Dr. Leo Francis Skinnider.

Dr. Gibson graduated in medicine at Glasgow University early in the last war and served with the R.A.M.C. at home and abroad. On demobilization he took over the old-established practice of Dr. William Russell of Paisley. He soon began to take an interest in public affairs, and for some years served on the town council, resigning in 1930, under the conditions of the new Local Government Act, on his appointment as visiting physician to two hospitals of the local authority—Craw Road and Auchentalie. He was elected to the magistracy in 1928. He was examiner to the St. Andrew's Association, lecturer to the Provident Co-operative Ambulance Corps, honorary surgeon to the Boy Scout movement and the leading figure in the local branch of the British Legion in its work in helping men who had served in the last war. He had been chairman of the Panel Committee and he was a member of the British Medical Association, having been elected in 1921. Another of his activities was his directorship of the Royal Victoria Eye Infirmary, the chairman of which at a meeting of the directors following his death, spoke of the great indebtedness of that institution to Dr. Gibson for his thirteen years' service.

Dr. L. F. Skinnider was a rather younger man. He graduated at Glasgow in 1924 and had been for fifteen years in practice in Paisley, where his father, the late Mr. A. S. Skinnider, was for a great many years a well-known journalist. He also was a member of the Paisley Panel Committee and since the time of his qualification, of the British Medical Association. Both men were highly respected in the local community, especially by their medical colleagues, and their tragic death is keenly felt. Dr. Gibson is survived by his wife and three children; Dr. Skinnider, who was a widower, by two small sons.

The sudden and tragic death of WILLIAM GRAY, caused by enemy action in Liverpool while carrying out his duties, was a great shock to his many friends in Edinburgh. He came from Canada in 1927 and graduated in Edinburgh in 1932. As a student (writes G. L. C.) he acted as one of the unqualified assistants in my surgical clinic in 1930. After graduating, the managers of the Edinburgh Royal Infirmary appointed him, at my request, resident house-surgeon to the wards under my charge. On the termination of this appointment, Mr. Pirie Watson, who, as assistant surgeon, had seen his good work, appointed him resident surgeon at Leith Hospital. Not content with a year of hospital work after graduation, Gray then went to Liverpool and specialized in orthopaedic surgery, obtaining the M.Ch.(Orth.) degree in Liverpool in 1937. Two years later he obtained the Fellowship of the Royal College of Surgeons, Edinburgh. At the time of his death he was deputy medical superintendent, Mill Road Infirmary, Liverpool. William Gray's record since graduation, so far as work is concerned, speaks for itself, but he had something more than ability—a charm, difficult to define, due to a bright personality, a lovable disposition, and a quiet musical voice, all of which endeared him to those who knew him. A promising career has been ruthlessly cut short. The deepest sympathy of all his friends is extended to his widow and his parents in Canada.

Dr. JOHN SLIGHT GRAY has been reported killed by enemy action in April, 1941, aged 28. He was the younger son of Mr. and Mrs. George Gray, of Riselaw Crescent, Edinburgh, and took the M.B. and Ch.B. at Edinburgh in 1939.

Universities and Colleges

UNIVERSITY OF LONDON

LONDON HOSPITAL MEDICAL COLLEGE

The College Board have made the following awards for 1941-2: Price Scholarship in Science (value £100).—A. J. Dinn. Open University Scholarships (a) (£100).—A. Comfort, Trinity College, Cambridge; (b) (£100).—K. A. A. Wray, King's College, Cambridge, and P. F. Haggart, Downing College, Cambridge (Scholarship divided).

UNIVERSITY OF OXFORD

Diploma in Ophthalmology, 1941

The Board of the Faculty of Medicine gives notice that the two-months course of instruction at the Oxford Eye Hospital will begin on Monday, October 13. The examination will be held beginning on Monday, December 8; names must be received at the University Registry not later than 3 p.m. on Wednesday, November 19.

Medical Notes in Parliament

Duty on Patent Medicines

On May 20, Mr. KEELING asked the Chancellor of the Exchequer whether he was aware that his predecessor, when withdrawing, in response to the views of the House, his proposal to discontinue the taxation of patent medicines, promised to re-examine the question of continuing to tax them, and repeated this promise to a deputation of members, whether the re-examination took place, and with what result. Sir KINGSLEY WOOD replied that on the outbreak of war, in view of the pressure on the time of all concerned, the procedure contemplated by his predecessor was abandoned. Subsequently, however, on August 13 last he gave an undertaking to see, before the next Finance Bill, whether he could not get the parties together and try to get some reasonable solution of the matter. Mr. Keeling was aware of the recent developments in this connexion.

MR. KEELING asked if Sir Kingsley Wood was aware that the only parties consulted were the vendors. Did the Minister think it right that the Government should have violated their express promise without any word of explanation. Sir KINGSLEY WOOD said he thought that the procedure now in operation was the best one possible. They could not have a long inquiry, but the Minister of Health was in touch with all parties interested in the matter. Viscountess ASTOR asked if the advertisement of patent medicines was not one of the scandals which was dealt with in the last war. No one knew why the Government had given in on this.

Liquid Fire Extinguishers

Many chemical liquids, for which the claim is made that they extinguish incendiary bombs, have been tested by the Research and Experiments Department of the Ministry of Home Security. None has been found which can be recommended in preference to water. Mr. MABANE in stating this on May 21 added that some of the liquids being sold are corrosive; some contain caustic substances dangerous to the eyes; others produce fumes and smoke which may be harmful and make fire-fighting difficult.

N.H.I.: Income Limit to be Raised

Mr. ERNEST BROWN announced on May 22 that the Government intended to introduce very shortly legislation to increase the benefits payable under National Health Insurance, in particular, sickness, maternity, and disablement benefits. This legislation could not, in present circumstances, be more than an interim measure designed to give effect to changes in the health insurance scheme necessary to meet wartime conditions. The Government hoped it would be possible to carry through in due course a thorough overhaul of the existing schemes of social insurance, particularly health and pensions insurance and workmen's compensation. It held that the comprehensive survey of the existing schemes which must be an essential preliminary to such legislation should be set on foot at once as part of post-war planning. The survey was to be undertaken forthwith by Mr. Greenwood in association with other Ministers concerned.

The Bill which the Government intended to introduce shortly would, as from the beginning of the next benefit year in January next, increase by 3s. the statutory rates of sickness and disablement benefits payable under the Health Insurance Acts. The sickness benefit for a man would be raised from 15s. to 18s., and his disablement benefit from 7s. 6d. to 10s. 6d. For single women and widows the new rates would be 15s. and 9s. respectively, and for married women 13s. and 8s. Any cash additional benefits would continue to be payable over and above these minimum rates. These changes would be made possible by the payment of State grant on the usual basis and by increasing by 2d. the weekly contributions payable in respect of men and women alike—1d. of this increase to be borne by the employer and 1d. by the insured person. The Bill would also raise to £420, as from January next, the remuneration limit for the compulsory health and pensions insurance of non-manual workers. In addition to other health and pensions rights, this would give to rather fewer than 500,000 fresh persons a title to free medical treatment and attendance. The position thus created was being discussed with the medical profession. Power would also be sought in the Bill to deal with the position in insurance of civilian prisoners of war and other similar war problems.

Ministry of Health Report.—Mr. ERNEST BROWN announced on May 8 that he proposed to issue from the Ministry of Health a summarized report covering the two years ended March 31, 1941, when this material had been collated. Sir FRANCIS FREMANTLE asked whether this reply referred to the Annual Report of the Chief Medical Officer of the Ministry or to the Report of the Department. Mr. BROWN: I shall do my best to have at least a summary published.

Combatant German Medical Personnel.—On May 20, Mr. SORENSEN asked the Secretary of State for War whether he had evidence to show that members of the German Army Medical Corps either were trained in the use of arms or employed them during action against our own or Allied troops. Captain MARGESSON said that no instances had been brought to his notice of the use of arms by German Army medical personnel in action against British or Allied troops, but he was making further inquiries. International law permitted the training of medical personnel in the use of arms in their own defence.

Notes in Brief

The number of death certificates received during the year 1939 in which vaccinia or vaccination was mentioned or the death was attributed to vaccinia or vaccination, and the ages in each case, were as follows: *Non-civilians:* 1 at 20 years. *Civilians:* 1 at 4 months and 1 at 31 years.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

A small increase, 38, in the number of cases of scarlet fever was reported in England and Wales, but only in four counties did the total differ appreciably from that of the preceding week—namely, London, Essex, and Yorkshire (West Riding) with increases of 10, 19, and 13 respectively, and a decrease of 18 where the notifications decreased by 25 cases. The returns for Scotland showed an increase of 25 cases.

The counties of England and Wales showed only slight variation in the number of notifications of diphtheria compared with the previous week. An increase of 19 was recorded for England and Wales and 7 for Scotland.

The notifications for dysentery, 103, were 3 less than in the preceding week. Local outbreaks were reported from two London boroughs: 15 cases in Islington (an institution) and 10 in Wandsworth. In Scotland 40 fresh cases were reported during the week, compared with 63 for the five weeks.

The incidence of enteric fever has been almost halved in England and Wales, and halved in Scotland. In the former country a quarter of the total was recorded in Middlesex—13 cases. Multiple cases were reported from Lydd 6, Warwickshire 5, Chester 4, and Northumberland 3.

Measles

The trend of the incidence of measles in Scotland is in striking contrast to that of England and Wales. The notifications in the latter country numbered 11,004, a reduction of 2,879 compared with the total of the preceding week. Two only counties from which increases were reported were Cornwall, Nottinghamshire, and Sussex where the notifications were 51, 65, and 44 respectively in excess of those recorded last week. In Scotland 242 cases of measles were notified an increase of 116. Two-thirds of the total were recorded in Lanarkshire, and 115 of these were in Glasgow.

Whooping-cough

The returns for whooping-cough showed the same contrasting trend between England and Wales and Scotland. In Scotland the notifications numbered 588, an increase of 284 on the last week and 614 above the previous fortnight. The returns are dominated by those of Glasgow where 714 cases were reported during the week under review. Although the notifications of whooping-cough in England and Wales were 99 less than in the previous week, the returns for several counties showed increases. The four fairly large increases reported were confined to small areas within the county. They were Middlesex, Finchley M.B.; Warwickshire, Birmingham C.B.; Yorkshire North Riding, Middlesbrough C.B.; and Yorkshire West Riding, Aldwick-le-Street U.D.

Cerebrospinal Fever

The incidence of cerebrospinal fever showed a slight increase in England and Wales: 17 more cases were reported than in the previous week. The only variation of any size that occurred between the notifications of the past two weeks was in London, where the cases rose from 22 to 37, dispersed throughout the metropolis. Twenty-one out of the twenty-eight metropolitan boroughs had at least one case during the week. The largest number of notifications in any borough was 4, and the boroughs with this number were Bethnal Green, Stepney, and Woolwich. In Scotland, where the incidence of cerebrospinal fever had been mounting during the previous three weeks, a large decline was recorded. The notifications for the past four weeks were 54, 77, 97, and 37.

G. R. Bakus and E. P. Griffin, jun. (*Amer. J. clin. Path.* 1941, 11, 252) report a case of teratomatous chorion epithelioma of the ovary in a virgin aged 13, who was operated on for appendicitis and on whom oöphorectomy was performed. Death due to metastases in the kidneys and lungs took place six months after the operation. The case is remarkable in that the majority of cases of chorion epithelioma are associated with pregnancy.

INFECTIOUS DISEASES AND VITAL STATISTICS

No. 13

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 3.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	1941 (b)	1941 (c)	1941 (d)	1941 (e)	1940 (Corresponding week) (a)	1940 (Corresponding week) (b)	1940 (Corresponding week) (c)	1940 (Corresponding week) (d)	1940 (Corresponding week) (e)

Medical News

The B.B.C. announces that a broadcast on the work of the Edinburgh Medical Missionary Society will be given in the Home Service on June 1 by Mr. W. J. Stuart.

The twenty-first annual meeting of the British Association of Dermatology and Syphilology will be held at Glasgow on July 11 and 12, under the presidency of Dr. W. H. Brown. The subject for discussion will be "Avitaminosis in relation to Skin Disease," which will be opened by Prof. J. W. McNee and Dr. G. W. Bamber. Further information can be obtained from the secretary, Dr. Henry MacCormac, 23, Wimpole Street, W.1.

The Quarterly Board of Westminster Hospital received on May 22 news concerning a new branch to be opened for in-patients in one of the Home Counties. The Board having previously agreed that a building should be obtained in which ward work could be carried on out of London, the Secretary reported that a very large property, in quiet surroundings, well equipped for adaptation as a hospital for 100 to 150 patients, had been found at a moderate yearly rental. Twenty beds in this building will be reserved for treatment of in-patients with radium.

The Hanbury Medal "for high excellence in the prosecution of original research in the natural history and chemistry of drugs" has been awarded to Harold King, D.Sc., F.R.S., of the National Institute for Medical Research, who has done important work on synthetic arsenical preparations and on the chemistry of alkaloids and sterols; also on hormones and the cardiac glucosides. The adjudicators of the medal are the Presidents of the Chemical, Linnean, and Pharmaceutical Societies, and the Chairman of the British Pharmaceutical Conference.

Agreement has been reached between the Ministry of Health and the British Hospitals Association on the financial adjustment to be made when, owing to enemy action, hospitals in vulnerable areas have to reduce their complement of beds and transfer civilian sick to institutions coming within the Emergency Hospitals Scheme. The expenditure of the hospital is to be apportioned according to the beds actually kept in commission for civilian sick and for casualties, and the hospital is to credit the Ministry with the number of "lost" civilian beds. This agreement is the subject of Circular 2308 sent by the Ministry to all voluntary hospitals in the scheme, and an accompanying document (War 184) gives details, including method of assessing bed complement in certain instances and the amount of the credit, and also the allowance to be made to hospitals for loss of patients' contributions.

The Ministry of Health is arranging for children in attendance at clinics to have black-currant syrup made from a formula drawn up by the Bristol University Agricultural Station. Black currants are well known to be very rich in ascorbic acid, and this syrup is stated to contain five times the vitamin C content of orange juice.

Prof. A. V. Hill, Sc.D., M.P., one of the secretaries of the Royal Society, has been elected a foreign associate of the United States National Academy of Sciences.

The Minister of Health has approved the appointment of Dr. N. M. Goodman and Dr. V. D. Allison as deputy senior medical officers of the Ministry.

Dr. Harold George Broadbridge has been appointed Coroner for West Middlesex in succession to Mr. R. Kemp, who retired recently.

Dr. Carl Neuberg, a German biochemist, has become professor of biochemistry at the New York University College of Arts and Science. He was formerly professor in that subject in Berlin, Amsterdam, and Jerusalem.

Following the increase in marriages there has been a big rise in the Australian birth rate. Births for the three months ending September 30, 1940, totalled 32,637, more by 1,353 than in the same period in 1939. There were 14,026 marriages in the last quarter of 1939—800 more than in the last quarter of 1938. New Zealand also reports an increased birth rate. The 1940 rate is the highest recorded since 1925, and the number of births registered exceeded the previous record total of 29,291 by nearly 3,000.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London;* SECRETARY, *Mediocra Westcent, London.*

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

LETTERS, NOTES, ETC.

"Whither Welfare?"

DR. G. ARBOUR STEPHENS (Swansea) writes: May I congratulate you highly on the splendid appearance of the *B.M.J.* of May 17, produced under conditions calculated to depress the most optimistic To everyone who has helped in so good a work be praise! I am very glad that during the stress you were able to place Sir Leonard Hill's letter (May 17, p. 764), even though it has a most peculiar tail. He calls attention to a most important article by Dr. Cicely Williams (May 10, p. 719). As one who started the first "mothercraft classes" for schoolgirls, and also the first mothers and babies welfare centre in Wales, I am in a position to appreciate much of what appears in that article. The great mistake is to assume that medical science and the medical profession are synonymous. The ability of the average man in any walk of life is a low one. The average teacher, preacher, plumber, or "doctor" is very badly informed. Dr. Williams points out that great discoveries in medical science are not implemented (except by the wholesale drug houses) by the medical profession, but what does the average medical man know or care about "science"? The preliminary science examination is no test of scientific knowledge, and the assumption of infallibility by one who has just scraped through a qualifying examination precludes all possibility of preventing disease by such a person. Fifty per cent. of our hospitals would be superfluous were we to feed ourselves properly.

"Bureaucratic Surgery"

Dr. ROWLAND COCKSHUT (Hendon) writes: The ingenuity of the human mind is infinite. One would not have thought it possible to contest Mr. Lake's conclusions, but Prof. Jefferson, defending the proposal to establish centres for the treatment of head injuries, including scalp wounds, says, "Once it had been decided to open these centres, the next question was, What types of injury were to go into them?" And Dr. F. M. R. Walshe says, "We have all been very ignorant of the incidence, range, and character of the abnormal neurological signs that may accompany apparently trivial scalp wounds." I submit that there is a lack of information of the incidence, range, and character of the results which may flow from sitting on a pin. They vary from acute septicaemia to the later appearance of the pin sticking out of the great toe. And the ultimate results, especially from the point of view of psychologists, of a good crack on the funny-bone in early youth are almost completely uninvestigated. I have been struck lately by the case of a man whose libido was released and whose Oedipus complex went into a fugue by a sound smack on the funny-bone. Now that the new centres are ready, what shall we put in them?—indubitably the traumatic pin-pricks and the traumatic funny-bones. My own two children had seven very traumatic cranial wounds at odd times which I stitched in the bath-room. *Fortunati ambo!* The children of the 1960 doctor will perhaps live in an age when there will be centres for head wounds, and, what is more, some sanitary inspector will force them to go there. I dedicate this letter to the untold millions of broken heads, stitched by ignorant practitioners who never knew that "abnormal neurological signs are to be found in a considerable portion of such cases by those who, trained to elicit them, make a systematic search for them." "Out of sight," sez you, "Out of mind," sez I.

New Dried Milk for Infants

The Ministry of Food will shortly supply under the National Milk Scheme a new dried milk with a modified cream content of 16% instead of the usual 27%. It is intended for babies under 12 months old who are likely to suffer from digestive troubles if fed on full-cream dried milk. As it may not be suitable for all infants, mothers applying for it should first obtain the advice of a doctor or a welfare centre. The new product will be known as "Half-cream National Dried Milk." The full-cream powder, however, will still be available.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY MAY 31 1941

General Medical Council

Opening of Summer Session

The summer session of the General Council of Medical Education and Registration was opened on Tuesday, May 27, under the presidency of Mr. H. L. Eason, C.B., C.M.G., who gave an address. Owing to damage by enemy action to the Council's premises, the session was held in the building of the Royal Institute of British Architects in Portland Place

Dr. D. F. Cappell, representative of the University of St. Andrews, and Dr. W. J. Wilson, representative of Queen's University of Belfast, being new members, were introduced by Dr. Campbell and Mr. Lowry respectively and took their seats.

Correspondence

State Medical Service

SIR,—The omniscience of the modern schoolboy is proverbial, as Dr. Hugh Paul points out in his trenchant and witty letter (*Supplement*, May 17, p. 68), and I would add that he is also well versed in the science of lexicology. He would most certainly not mistake a generalization for a declaration or an edict, though he might be tempted to confuse it with a dogma, but this would be excusable on the grounds of youth and inexperience. My comment was not aimed at any of the antlered stags mentioned by Dr. Paul, nor even at the M.O.H. for Smethwick, or any other town or borough; it concerned the rank and file of the medical profession only.

By flinging the facile taunt of commercialism, Dr. Pybus (*Supplement*, May 10, p. 58) makes good use of that valuable legal aphorism, "When you have a bad case to defend abuse the plaintiff's attorney." But I do not accept his soft impeachment. It is, in my opinion and that of many of your correspondents, high time to review the whole question of medical finance in an atmosphere cleared of suspicion and false shame. Medicine does not benefit by being harnessed to commerce, I agree, but it suffers by being shrouded in a cloak of genteel poverty. In any scheme for the future of medicine the financial aspect is the least important, but that does not mean it is to be denied very careful consideration. My alternative scheme did not pretend to be an accomplished fact; it was intended to show that the profession must, and could be, *faber et magister suae fortunae*.—I am, etc.,

Beckenham, May 21. ALAN MARSH.

SIR,—I have read all the letters and articles about this most interesting subject in your columns, but what strikes me is that so far no one has ventured to state definitely how the introduction of such a service will affect his daily life, apart from being relieved of bad debts and having a fixed income taxed at the source. Surely it is obvious that if introduced a State Medical Service will entangle our lives to a greater extent than mere financial matters. For instance, there will be the question of the distribution of medical personnel throughout the country. Now, can any of the advocates of the service assure me that I can settle down in any part of this island I care to choose to practise my profession, or will it be my lot to be sent to whatever part the dictates of distribution compel someone in Whitehall to put me? If I am established in practice in Oxford, can I be assured that I can remain there and be free from the possibility of my being sent to, say, Wigan against my will? To me that is the essential meaning of "service" in this sense. We shall individually be like the employees of the G.P.O., in so far as we shall be liable to be uprooted from places where we have made our lives and be transferred elsewhere in the customary frigid manner which the State uses towards anyone it happens to employ.

Will the country be cut up into regions based on teaching hospitals or medical schools, and will such regions be exclusively served by medical men educated in the parent teaching hospitals? Is the service to be governed by the profession with the addition of a few lay members, or are our lives to be laid at the mercy and whims of local or national politicians? It cannot be refuted that a doctor should be in a position to act fearlessly according to his conscience like a High Court judge, instead of having to risk his post in the process. Can a State Medical Service be run on lines which can assure us enough independence to give our opinions without fear or favour?—I am, etc.,

Bristol, May 17. OLIVER SLOAN.

Increase in Private Fees

SIR,—In the report of the proceedings of Council of the British Medical Association at a meeting on April 23 (*Supplement*, May 3, p. 54), a recommendation by Dr. Bone was agreed to, "that an increase of fees has been rendered inevitable by rising costs, and that practitioners in general practice be recommended to increase their private fees, including contract fees, by not less than 20%." This has since been duly advertised in the lay press. At the present time the majority of patients in general practice are suffering loss and hardship. In a great many cases it is essential to reduce fees and not to raise them. Every effort is being made by the Government to control rising prices to prevent inflation. This advice by the Council of the Association is, in my opinion, both unpatriotic and unwise, and I note it was made on the recommendations of a few Divisions. I cannot believe that it represents the opinion of the bulk of the medical profession.—I am, etc.,

Bournemouth, May 20. E. D. GRANGER, M.D.

Capitation Fee

SIR,—A meeting of the Bristol Panel and Local Medical Committee was held on May 6 at which the capitation fee was discussed. It was noted that the profession was informed in the *Supplement* of December 21, 1940 (p. 57) that "an application is being made to the Ministry of Health for a wartime increase in the annual capitation fee for the treatment of insured persons." It was further noted that in the *Supplement* of April 26, 1941—eighteen weeks later—the Insurance Acts Committee stated that the Ministry had refused the application, and that "the general feeling of the Committee . . . was that the claim on the ground of increased cost of living should not at the moment be pursued," but it "resolved to proceed with the claim on the ground of increased practice expenses."

The Bristol Panel and Local Medical Committee feels that the refusal of the Ministry to accept the application is a serious blow to panel practitioners. It views with grave concern the fact that the Insurance Acts Committee is so out of touch with, or lacking in sympathy for, the wishes of the panel practitioner that it has decided not to pursue the claim on the ground of increased cost of living at once. It views with even graver concern the fact that the Insurance Acts Committee, after stating that it "had withheld the application until the circumstances placed beyond doubt the justification of such a course," had not the courage of its convictions to carry the application to a logical conclusion.

The committee is of opinion that the reasons for the claim are so obvious that it need not stress them, but it would point out that the war has brought for panel practitioners much extra gratuitous work, such as the treatment of insured persons wounded in air raids and the signing of innumerable

forms dealing with such things as gas masks, milk, and Service allowances. The committee believes that the present high morale and determination of the civil population depend, especially in badly raided areas, very largely on the doctors who come in intimate contact with the people. This causes great strain on their own resolution and cheerfulness, and the strain should not be increased by an anxiety over financial matters and by a knowledge of lack of consideration for their justifiable claims. Noting that the Insurance Acts Committee would put forward the application "if comparable sections of the community received an increase of remuneration," the committee regrets the absence of any information that the Insurance Acts Committee is taking the obvious course of approaching the recognized organizations of comparable sections of the community to present a united front and avoid one section being played off against another so that all fall separately in the best Continental and Balkan manner. Finding incidentally that, following representations by the British Medical Association, the Minister of Health has approved the payment of cost-of-living bonus to certain medical officers employed by local authorities (*Supplement*, January 11, 1941, p. 6) the committee points out that either these officers are of an inferior status or that a comparable section of the community is already receiving an increase of remuneration, and the claim should therefore be put forward by the Insurance Acts Committee.

With these considerations in view the Bristol Panel and Local Medical Committee unanimously resolved:

1. That the Insurance Acts Committee should be asked to call an immediate meeting of the Conference of Panel and Local Medical Committees, to decide the future action of the Insurance Acts Committee in the matter of the claim for an increased capitation fee.

2. That if a meeting of this conference in wartime is impossible, the members of the Insurance Acts Committee should ascertain the views of Panel and Local Medical Committees by personal contact and thereafter act on these views.

3. That these observations and resolutions be sent to the Insurance Acts Committee, all Panel and Local Medical Committees, and to the *British Medical Journal* for publication to inform panel practitioners in general.—We are, etc.,

R. BURGES, Chairman.
J. A. BIRRELL, Secretary.
May 14. Bristol Panel and Local Medical Committee.

Medical Services of H.M. Forces

Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieuts. M. R. W. Wynn-Williams, W. S. Larcombe, W. Weir, S. A. Bather, D. A. Tolhurst, R. E. Rainey, and W. A. Cavanagh to be Temporary Surgeon Lieutenants.

ARMY

Colonel W. L. E. Fretz, late R.A.M.C., having attained the age for retirement has retired on retired pay.

Lieut.-Colonel (temporary Colonel) J. G. Gill, D.S.O., O.B.E., M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Major (temporary Lieut.-Colonel) E. S. Cuthbert to be Lieutenant-Colonel.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

The surname of Lieut.-Colonel I. R. Hudleston, D.S.O., is as now described, and not as notified in the *London Gazette* dated April 15.

Captain C. W. Sparks, M.C., and Captain (temporary Major) L. J. Shell, M.C., to be Brevet Majors under the provisions of Article 168, Royal Warrant for Pay and Promotion, 1940.

War Substantive Captain C. W. Simpson, M.C., has ceased to belong to the Reserve of Officers on account of ill-health. (Substituted for the notification in the *London Gazette* of April 15.)

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonel G. W. R. Bishop, T.D., from Somerset Light Infantry, to be Lieutenant-Colonel.

Majors E. White and L. G. Llewellyn, from R.A.M.C., Temporary Commissions, to be Majors.

Major A. R. Muir, having attained the age limit, has relinquished his commission, and retains his rank.

War Substantive Captain D. J. A. Alban-Jones has taken rank and precedence in his Corps and in the Army as if his appointment as War Substantive Captain bore date July 13, 1940.

Supernumerary for Service with Queen's University, Belfast, Contingent, Senior Division, Training Corps (Medical Unit).—J. R. Wheeler and W. A. Brown, late Surgeon Sub-Lieutenant, R.N.V.R., to be Lieutenants.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

D. McAlpine to be Lieutenant, and has been promoted to the rank of acting Colonel.

F. M. Stewart to be Lieutenant, without pay and allowances, and has been ng rank of Major.

The Army Dental Corps, to be Captain.

has *relinquished* his commission.

:ains J. P. Watson and N. H. M. R. Monro have ...esions on account of ill-health.

...ding Lieut. L. L. Ratazzi in a *Supplement* to the *London Gazette* dated January 6 is cancelled.

Lieut. B. P. O'Hara has resigned his commission.

Lieut. J. E. B. Morton has relinquished his commission on account of ill-health.

To be Lieutenants: G. Haggar, G. N. Braham, O.B.E., S. G. Alavoine, J. D. Ball, F. L. Bland, H. J. S. Coldham, J. A. Harper, J. C. Hislop, K. Lumsden, H. I. Maister, C. E. S. Myers, M. P. O'Driscoll, T. A. Shannon, F. M. S. Smith, K. H. Tallerman, F. B. Thomas, R. W. Thompson, R. D. Borthwick, T. B. D'Costa, C. E. Friskney, I. Gilbert, L. S. Glass, K. K. Kcamaris, G. R. Millar, R. Mitchell, J. W. Taylor, R. M. Wink, W. G. L. Flather, F. G. Hunter, R. S. Illingworth, A. Ross, G. D. Malcom, J. MacKenzie, A. C. Price, T. E. Marshall, C. W. R. Price, J. J. L. Ablett, E. A. Clegg, C. C. Corfield, S. Durham, M. Latner, J. Markowitz, L. C. Oliver, P. R. Saville, C. M. Seaward, P. Tettmar, J. B. Tolmie, W. N. Vellacott, R. W. Black, R. Good, D. Purdie, D. Valerio, A. S. Baker, W. Fraser, R. A. Furniss, N. E. Maby, H. A. Taylor, R. H. Cuthbert.

Supernumerary for Service with Aberdeen University Contingent Senior Division, Training Corps (Medical Unit).—J. F ...

Supernumerary for Service with Edinburgh ... ior Division, Training Corps (Medical Unit).—D. C. ... ello to be Lieutenants, the latter without Army pay and allowances.

To be Medical Officers with the relative rank of Lieutenant: Kathleen H. McKenna, Kathleen M. Matthews, Jean S. Riach, Dora J. B. Falconer.

THE ARMY DENTAL CORPS

W. Rotheram to be Lieutenant.

ROYAL AIR FORCE

ROYAL AIR FORCE VOLUNTEER RESERVE

Flight Lieut. D. McGregor has resigned his commission.

To be Flight Lieutenants for the duration of hostilities: J. B. Mutch, B. C. Nicholson, P. J. Nyhan and H. G. Roberts.

Flying Officers W. A. Bridgwood, B. Burns, K. R. Hudson, J. S. A. Linton, E. R. Brown, R. S Castle, G. T. B. Mackinnell Childs, A. J. B. Phillips, G. Pollock, P. Wilson, F. R. Buckler, J. W. Garraway, A. P. Gorrie, A. I. McKendrick, E. E. Phillipp, J. F. J. Hickey, E. W. Melvin, W. B. James, D. D. Morrell, L. M. Rouillard, G. C. W. James, E. B. D. Bangay, W. Anderson, J. Graham, R. Cuddeford, G. Oppenheimer, H. C. Thomas, M. S. C. Stephens, L. B. Furber, A. H. Jack, C. Joseph, C. B. I. Willey, D. S. Young, P. M. Davies, A. R. Farmer, D. R. Gray, L. M. Magurk, J. F. Houlihan, L. W. Aldridge, G. P. Barclay, and J. Watson have been promoted to the war substantive rank of Flight Lieutenant.

Miss Annie D. M. Adams has been promoted to the relative rank of Flight Lieutenant.

To be Flying Officers for the duration of hostilities: H. S. Boyce, A. R. Bradley, G. H. Campbell, K. Harrison, H. Jefferson, E. O'C. Parsons, A. Ponder, E. S. Reed, J. Simpson P. N. Stanbury, P. Steen, B. A. D. Stocker, P. V. Suckling, G. W. E. Walker, G. B. Will, P. B. Willan, J. J. Williams, H. Carr, F. J. S. Chapman, P. H. Davies, E. H. Gordon, E. L. Graff, D. S. Grant, R. G. P. Heard, T. Hepburn, E. I. Holloway, E. K. Jones, D. R. Levinson, J. W. G. McDougall, D. A. Osborne, J. M. Russell, W. Sinclair, H. J. M. Stratton, R. D. Tonkin, M. W. L. White.

The notification concerning P. E. Percival in the *London Gazette* dated April 11, 1941, should read Perceval.

IN

Agranulocytosis

PROMPT TREATMENT IS ESSENTIAL

Agranulocytosis usually runs a rapid course to a fatal termination unless prompt and adequate measures are taken. If it is suspected in patients under treatment with drugs which have been associated with the occurrence of leucopenia, immediate withdrawal of the causative agent is, of course, indicated. When the diagnosis has been made, the prompt administration of 'Pentnucleotide' in adequate dosage may mean the difference between success and failure.

'Pentnucleotide'

Full information on this mixture of the sodium salts of pentose nucleotides for intramuscular use will be sent to any interested physician on request.

THE CALCULATION AND PRESCRIBING OF INFANTS' FEEDS

I. AFTER THE NEONATAL PERIOD: THE USE OF STANDARD MIXTURES

BY

HELEN M. M. MACKAY, M.D., F.R.C.P.

Physician to the Queen's Hospital for Children, Member of the Staff of the Medical Research Council

The evacuation of babies from cities results in infants of all sorts of feeds arriving in country towns and villages or outlying hospitals, and among the many causes of the drift back to evacuation areas of mothers and babies is difficulty in obtaining help with problems in infant feeding. When so many doctors and nurses whose previous experience has been in other fields of medicine are being called upon to deal with infants in overcrowded clinics, it is hoped that a paper such as this may be of service to some practitioners who have to give instruction in a subject with which they are not thoroughly familiar.

Far the commonest of the gross errors in infant feeding are quantitative; these often arise from difficulties in calculating the calorie value of individual feeds, from failure to estimate the whole twenty-four-hour intake, and from errors in measuring. The object of this paper is to suggest how some of the common problems in infant feeding may be met, and labour minimized, by making up all infant feeds in dilutions to provide 20 calories per fluid ounce—the calorie value of breast milk. Breast-feeding is, of course, to be preferred to artificial feeding, but the management of breast-feeding is not here considered.

Instruction of Nurses in Calorie Requirements

It is necessary for all nurses concerned with infant feeding to know something of calorie values and of how to calculate a baby's approximate quantitative needs, and this they will quickly learn to do if put on the right track. It is helpful to provide nurses with some tabulated information, to be hung up in the ward kitchen, day nursery, or infant consultation room, as the case may be. Tables are here given with this end in view; they can be considerably shortened by those doctors proposing to use only a few foodstuffs for infants.

Table I shows the calorie value in round figures of some of the foodstuffs commonly used for infants in this country. The figures are approximate only, as shown by the following examples: (*a*) The average calorie value per ounce of human milk or cows' milk is probably nearer 19 than 20, but to simplify calculations 20 is generally used for practical work. (*b*) The solids in dairy milk amount to approximately 12½%, and to reconstitute milk on this basis 56 grains of milk powder are required with enough water to make 1 fl. oz. of mixture. However, in this table round figures are again inserted, and 60 grains or 1 drachm (troy) of milk powder is given the calorie value of 20. (If, in fact, 19 is the average calorie value of 1 fl. oz. of dairy milk or of 56 grains of powder, then the calorie value of 60 grains of powder would be 20.4. Thus on this basis the approximate figure 20 given in the table is correct to the nearest whole number.) (*c*) The average caloric value of 1 fl. oz. of sweetened condensed milk is very variable, but is over 100 calories; however, for practical purposes the round figure of 100 is near enough. (*d*) One must remember that domestic measures used for the measurement of feeds are subject also to a considerable margin of error. The use of domestic measures is further considered in a later section.

TABLE I.—*Calorie Values (approximate) of Foodstuffs for Infants*

Foodstuff	Calorie Value
Human milk	20 calories per fl. oz.,[1] 400 calories per pint
Cows' milk	20 ,, ,, ,, [1] 400 ,, ,,
Dried milk	
Full-cream milk	20 calories per drachm (troy) or per level measure[2]
Half-cream milk unsweetened	16 ,, ,, ,, ,, [2]
Half-cream milk, sweetened	16 ,, ,, ,, [2]
Skimmed milk	13 ,, ,, ,, [2]
Protein milk	Usually about the same as full-cream dried milk
"Humanized" milk	,, ,, ,, ,, ,, ,,
Condensed milk	
Sweetened	100 calories (or more) per fl. oz.—say, 20 calories approximately per level teaspoonful[3]
Unsweetened	60 calories (very variable) per fl. oz.—say, 12 calories approximately per level teaspoonful[3]
Dried whey	12 calories per drachm (troy) (very variable)
Sugar	15 calories per drachm (troy)
Castor or granulated	15 calories per level teaspoonful[3]
Fats and oils	35 calories per drachm (troy) 50 calories approximately per level teaspoonful[3]
Cereals	12 calories per drachm (troy)
Benger's	60 calories per drachm (troy) 50 calories approximately per level dessertspoonful[4]

[1] For measuring fluid milk or water when no proper graduated measure is available, use the baby's bottle. Do not use tablespoons.
[2] For measuring dried milk the measure supplied for that particular milk powder by the makers should always be used.
[3] For measuring condensed milk (when no graduated measure is available) or for measuring castor and granulated sugar, use a large domestic teaspoon holding just over 1½ drachms (1.6 fl. dr.) by volume.
[4] For measuring Benger's food, use a dessertspoon, holding 1·2 fl. oz. by volume.

Table II gives some simple instructions to nurses for calculating calorie requirements. In essentials it amounts to starting a baby newly under observation on the calorie equivalent of 1½ to 2 oz. of breast milk per pound of body weight per day, and increasing to 2½ oz. or more according to the baby's appetite and progress. Scales of approximate calorie requirements are essential in infant feeding, but naturally any scale must be used with due regard to the individual baby. For the normal baby, appetite and rate of gain in weight form very good criteria of whether or not he is receiving about the right quantity of food, and mothers should be instructed not to press infants to take more than they want. No directions are given in the table concerning the quantitative requirements of the newborn, as this is a subject which cannot profitably be dealt with in a few sentences; it is considered in Part II of this paper.

TABLE II.—*Calorie Requirements per Pound Body Weight in 24 Hours*

Babies of normal weight:
1 week to 5 months old: 50 calories (2½ oz. breast milk or "standard mixture") per lb. body weight.
5 months to 7 months old: about 50 calories, decreasing to, say, 45 calories per lb. body weight.
Thin babies and premature babies:
These require more—say, 55 to 65 calories (2¾ to 3¼ oz. breast milk) per lb. body weight, if they can digest it. Premature babies may temporarily need still more, but should always be started on small feeds.
Fat babies:
These require rather less per lb. body weight than babies of normal weight.
Newborn babies:
The figures given above do not apply to newborn babies, whose food intake in the first days of life is small and increases gradually.
Example of calculation of feed:
A baby weighing 10 lb. is to be given 50 calories per lb. body weight in 24 hours, or 10×50—i.e., 500—calories in the day. If this is made up in the strength of 20 calories per fl. oz. he will require 500÷20—i.e., 25—oz. per day, or five feeds of 5 oz. each, or six feeds of about 4 oz. each.
It is usually wise to start a baby newly under observation on perhaps two-thirds of his full requirement, and work up to the full amount gradually by the end of two or three days if he is taking satisfactorily: sudden large increases in the calorie intake are always risky.
Normal rate of gain:
Babies making satisfactory progress should gain as follows: Under 5 months old, about 6 oz. weekly; 5 to 12 months old, about 4 oz. weekly.

Advantage of Standardizing the Calorie Concentration of Feeds at 20 Calories per Fluid Ounce

If large numbers of babies have to be dealt with the difficulties of supervising feeds are for most of us insuperable without some standardization. By consistently using standard mixtures or solutions, each providing, like breast milk, approximately 20 calories to the fluid ounce, the whole problem can be enormously simplified and labour reduced.

Table III shows the quantities of various foodstuffs, with water, required to provide approximately 20 calories per

TABLE III.—*Standard Mixtures and Solutions containing approximately 20 Calories per Fluid Ounce*

Dried milk, full-cream[1,3]	1 dr. (troy) or 1 level measure
With water to	1 fl. oz. (measured with graduated measure or feeding bottle)
Dried full-cream lactic acid milk[1]	Ditto
Dried protein milk[1]	Ditto
Dried humanized milk[1]	Ditto
Dried milk, half-cream[1]	1½ dr. (troy) or 1½ level measures
With water to	1 fl. oz. (as above)
Condensed milk, sweetened[2,4]	1 fl. oz. or 1 level teaspoonful
With water to	5 fl. oz. or 1 fl. oz.
Condensed milk, unsweetened[2]	1 fl. oz. or 1½ level teaspoonfuls
With water to	3 fl. oz. or 1 fl. oz.
Sugar, cane[2]	1½ level teaspoonfuls
With water to	1 fl. oz.
Sugar, lactose[2]	2 level teaspoonfuls
With water to	1 fl. oz.
Cows' milk	10 fl. oz.
Sugar (cane)[2]	8 level teaspoonfuls
33% fat emulsion	1 fl. oz.
With water to	20 fl. oz.

[1] Roller-process-dried milk should be freshly mixed for each feed. Ladle the milk into the makers' measure and level it off without compressing it. Never measure it with a teaspoon. Half-cream unsweetened dried milk and the so-called half-cream milk powder to which lactose has been added by the makers are of about the same calorie value, and 1½ level measures in a fl. oz. provides about 20 calories per fl. oz.
[2] The teaspoon used for measuring sugar should hold just over 1½ fl. dr.—the same-sized spoon will serve for condensed milk if no suitable graduated measure is available.
[3] A 1-lb. packet of full-cream milk powder per week provides daily about 17 measures, or 17 fl. oz. of reconstituted milk. A 20-oz. (avoir.) tin of milk powder per week provides daily about 20 measures, or 20 fl. oz. of reconstituted milk.
[4] A tin of sweetened condensed milk holding approximately 1/2 pint provides about 2½ pints of standard 1-in-5 mixture.

fluid ounce—the so-called "standard" mixtures of this paper. When feeds have to be made up for a number of babies in a ward they can conveniently be ordered as "standard" mixtures or solutions (see Table IV, last column). Sugar solutions can be mixed once daily and measured out as required for each feed in the day. Dried milk or condensed milk can be mixed at feeding times in one bowl for several babies, and from the "standard" mixture so prepared the necessary volume measured for each infant. On the other hand, if directions are given to the mother the use of the term "standard" mixture is merely confusing to her: she should be told to make up each feed as it is required by her baby, and to give such and such an amount of each constituent, with water to the required number of ounces (as shown in Table IV, third column).

If all the feeds ordered provide 20 calories per fluid ounce the calorie intake for the day is easily estimated, and if the feed is altered from full-cream dried milk to half-cream dried milk or sweetened condensed milk no intricate arithmetic is involved, as this simply means the exchange of one "standard" mixture for another, ounce for ounce (see Table IV). Without some such basis a

TABLE IV.—*Examples of Feeds containing approximately 20 Calories per Fluid Ounce*

Volume of Feed	Foodstuff	Quantity	As Standard Mixtures or Solution
			fl. oz.
2 fl. oz.	Full-cream dried milk	1 level measure	1
	Sugar	1½ level teaspoonfuls	1
	Water to	2 fl. oz.	
	Full-cream dried milk	1½ level measures	1½
	Sugar	1 level teaspoonful	½
	Water to	2 fl. oz.	
	Half-cream dried milk	1½ level measures	1
	Sugar	1½ level teaspoonfuls	1
	Water to	2 fl. oz.	
	Half-cream dried milk, sweetened	2½ level measures	2
	Water to	2 fl. oz.	
	Dairy milk	1 fl. oz.	1
	Sugar	1½ level teaspoonfuls	1
	Water to	2 fl. oz.	
	Sweetened condensed milk	2 level teaspoonfuls	2
	Water to	2 fl. oz.	
3 fl. oz.	Full-cream dried milk	2 level measures	2
	Sugar	1½ level teaspoonfuls	1
	Water to	3 fl. oz.	
	Dairy milk	2 fl. oz.	2
	Sugar	1½ level teaspoonfuls	1
	Water to	3 fl. oz.	
5 fl. oz.	Full-cream dried milk	4 level measures	4
	Sugar	1½ level teaspoonfuls	1
	Water to	5 fl. oz.	

baby's feed may be unintentionally doubled or halved in calorie value, with the ill results one would expect. Other reasons, besides simplicity, for giving food of the same calorie concentration as breast milk are that a concentrated feed may lead to overfeeding as a result of thirst, and a dilute feed may be vomited on account of its large bulk. Again, a small or feeble baby offered a dilute feed is likely to weary and to take less than he needs. It is often supposed that by diluting with water so as to provide, say, 10 calories instead of 20 calories to one fluid ounce the feed is made more easily tolerated, but this view is not supported by experience; in fact, a baby inclined to vomit is more likely to keep down the more concentrated feed if both provide the same total calorie value. When nurses have charge of a number of babies on bottle feeds a considerable reduction in labour results from standardizing feeds. Occasionally a dilute feed or a concentrated feed is indicated for some special purpose—for example, concentrated feeds are useful for some babies who vomit from habit, but this does not detract from the usefulness of "standard" mixtures for general use.

Measurement of Feeds

Errors in measuring are a constant source of difficulty. For example, fluids (dairy milk or water) are often ordered and measured in tablespoonfuls, each tablespoon being reckoned as half a fluid ounce, whereas most tablespoons actually hold three-quarters to one fluid ounce, so that this may introduce a 100% error. A dessertspoonful is nearer half an ounce than is a tablespoonful, and many London mothers call a dessertspoon a tablespoon. Naturally, proper graduated measures should be used when available.

Even the poorest mother usually possesses a feeding-bottle graduated in ounces, which, if not an accurate measure, is at least much better than a tablespoon. The method of measuring water requires to be explained to a mother. She should be told to mix the feed (dried milk and sugar, or condensed milk) with a small quantity of water, to pour it into the bottle, and add water to the required mark.

Dried milk and sugar are habitually ordered by weight (in drachms troy) and measured by volume. Since the bulk of the same weight of different milk powders varies widely, the amount of each particular milk powder should be gauged by the measure provided by the makers. The powder should be poured into the measure with a spoon and levelled off without compression. The common practice of dipping the measure into the packet and flattening it off against the side results in considerable compression, and hence in overfeeding. Heaped teaspoonfuls are hopelessly inaccurate measures for milk powder. When all care is taken there is still a large personal error; hence in hospital it is desirable that from time to time nurses should check their measurements by actual weighing of measured quantities. Mothers who have no suitable scales can check their measurement by noting how long a packet of known weight lasts. A 1-lb. packet of full-cream dried milk provides in round figures 6 pints of reconstituted milk (more exactly, 5.82 pints containing 60 grains in each fluid ounce); thus one packet a week provides about 17 fl. oz. (more exactly, 16.6 fl. oz.) of milk daily. A 20-oz. (avoir.) tin of national dried milk provides about 7 pints of reconstituted milk (or more exactly, on the same basis as above, 7.29 pints, and a tin a week 20.8 fl. oz. daily). Thus a daily intake of 20 measures of powder—i.e., 20 oz. of reconstituted milk—is equivalent to a weekly intake of about 1¼ packets of the ordinary 1-lb. size, or one tin of national dried milk size. A daily intake of 25 measures is equivalent to a weekly intake of about 1½ packets of the smaller size, or about 1¼ tins of the larger size, and so on. If a baby is not progressing normally on a theoretically adequate feed the quantity of dried milk used in a week should always be checked.

For sugar no measure is usually provided. A large teaspoon may be used. For granulated or castor sugar the teaspoon should hold just over 1¼ fl. dr., and a teaspoon of this size should be shown to the mother or, better still, her own spoon be checked. One level teaspoonful of sugar will then be approximately 1 drachm (troy). Lactose varies in weight of a given bulk, but usually a teaspoonful (using the same large teaspoon) is considerably less than 1 drachm.

Condensed milk should, when possible, be measured with a graduated measure. A feeding-bottle is not a satisfactory measure for condensed milk on account of the relatively small volume to be measured. Both sweetened and unsweetened condensed varieties vary widely in calorie value. If the sweetened is reckoned as 100 calories per fluid ounce (an under-estimate in most cases), then 1 in 5 by volume provides a mixture with 20 calories to each fluid ounce. Hence for each fluid ounce of mixture 1.6 fl. dr. of this milk is required—i.e., say one large teaspoonful (level) with water to one fluid ounce. A teaspoonful in an ounce is often called a 1 in 8 dilution, forgetting that a teaspoonful and a drachm are far from synonymous. If the unsweetened condensed milk is reckoned as 60 calories per fluid ounce, then 1 in 3 by volume, or, say, 1⅔ large teaspoonfuls (level) in 1 fl. oz., provides nearly 20 calories per fluid ounce. The calorie value supplied in condensed milk feeds is apt to be somewhat uncertain on account of the various sources of error, but nevertheless condensed milk feeds are very valuable for premature and feeble infants as well as for newborn babies for whom breast milk is not available. Sweetened condensed milk supplied in a tin holding about half a pint and diluted 1 in 5 provides about 2½ pints of "standard" mixture with 20 calories to each ounce, and calculation of the amount required in a week is an important check on teaspoon measures.

Type of Feeding

The use of "standard" mixtures as here advocated does not tie one down to any one type of feeding: dairy milk, dried milks, or condensed milks can be used with the desired proportions of sugar or with added fat emulsion and sugar (see Tables III and IV). Under the Government scheme for the supply of milk at a cheap rate for infants, at present milk in only two forms is available—i.e., either dairy milk at 2d. per pint or national dried milk (full-cream roller-process-dried milk) at 2d. per reconstituted pint—or free for those parents under a certain income level. It seems likely that the majority of bottle-fed babies in the country will before long be fed on fluid milk or on this powder, more especially as difficulty is already being experienced by mothers in obtaining proprietary processed milks. In common with the majority of paediatricians and infant welfare medical officers in this country I prefer dried milk to dairy milk for routine use for babies in working-class homes on account of its greater safety. Full-cream dried milk carefully used, with varying additions of sugar, will be tolerated satisfactorily by most babies *of normal digestive capacity*, at least after the first few weeks of life. But for babies of poor digestive capacity other processed milks are required if lives are not to be lost unnecessarily. Sweetened condensed milk is needed for premature or feeble infants, for babies in the neonatal period, and for other babies who readily vomit. So-called half-cream dried milk to which lactose has been added in liberal amount by the manufacturers is much used for young and feeble infants, and should usually be given without added sugar, since it already contains a liberal amount. Half-cream dried milk to which no sugar has been added by the makers and dried protein milk are desirable for the treatment of many cases of diarrhoea. Whether or not these will be available in the coming months seems uncertain.*

Vitamin D and iron are supplements which should be provided for all babies. The cheapest and most efficient method of giving these as a routine to artificially fed babies would be by using on a large scale dried milk in which both have been incorporated in adequate amount. But since an iron-fortified milk powder is not quite as easily tolerated as the same milk without added iron, it is wise to begin its administration gradually, as described below. So used, there is no difficulty in getting any baby who is not already upset or suffering from diarrhoea to tolerate it. Unfortunately dried milks fortified with vitamin D and iron are not available under the National Milk Scheme, and proprietary milks (many of which are so fortified) cost 80% to 24% more.

My usual routine when using dried milk, either full-cream or unsweetened half-cream, is to give in each feed approximately 20 calories in added sugar (i.e., 1 oz. of "standard" sugar solution, or 1½ level teaspoonfuls of cane sugar in 1 oz. of water) and the rest of the feed in "standard" dried-milk mixture. Thus if a baby has a 2½-oz. feed he will have 1½ fl. oz. of dried-milk mixture (half- or full-cream) and 1 oz. of sugar solution, or if he has a 7-oz. feed he will get 6 oz. of dried-milk mixture (full-cream) and still 1 oz. of sugar solution. Babies on small feeds thus get a much larger proportion of the feed in added sugar, the most easily digested part of the diet. More than half the total calories, however, should not be given in added sugar; hence in feeds of under 2 fl. oz. the

* Since this article was written the Ministry of Food have undertaken to issue a national half-cream dried milk (unsweetened) for infants.

amount of " standard " sugar solution will necessarily be less than 1 oz. For many tiny and feeble babies a high sugar feed, temporarily, is desirable, though it must be remembered that babies with loose stools often tolerate a high proportion of sugar badly. If a diet in which only half the calories are supplied as milk is long continued the risk of deficiency disease developing is considerable; therefore as soon as possible the proportion of milk in the feed should be increased and vitamins and iron supplements should be added. If more than 50% of the total calorie intake is given as added carbohydrate there is serious risk of carbohydrate dyspepsia, and loss of weight may be rapid, with irritating frothy fluid stools. As regards choice of sugar, lactose is more expensive than cane sugar and probably has no advantage over it. Sweetened condensed milk provides a feed in which about 40% of the total calories are in added cane sugar, and the commonly used sweetened half-cream dried milk a feed in which, say, 27% of the calories are in added lactose.

Supplementary Feeds

Mothers arriving in reception areas with their babies are likely to be tired, and many will have had a harassing time; as a result their lactation will often prove temporarily insufficient, and if the baby is hungry and cries much of the night his mother's milk will quickly fail, and he and his mother will not be welcome additions to any household. In such cases there should be no hesitation in supplementing one or more feeds each day. If the situation is explained to the mother and her co-operation sought it should often be possible gradually to diminish and cut out the artificial feeding when the mother has been able to settle down in new quarters. By finding those feeds following which the baby cries one can gain a fair idea which feeds it is necessary to supplement, and a co-operative and sensible mother should always be given latitude in adjusting the quantity to the baby's needs. When it is not possible to carry out many test feeds the baby's appetite, together with his rate of gain in weight, usually provides a good indication of the amount of bottle-feeding required.

Symptoms of Underfeeding and of Overfeeding

Underfeeding, however, very often goes unrecognized for many weeks. This is attributable to two main causes: (*a*) many are not familiar with the symptoms, and (*b*) the baby's estimated calorie intake is not compared with his calculated needs. The underfed vigorous full-term baby 4 weeks old and upwards will probably take his feeds eagerly, cry when the feed is finished, and cry before the next one is due—and of course either gain weight at a slow rate or lose in weight. If breast-fed he will suck for a few minutes and then turn away crying, so that the mother often concludes that he refuses to suck because he is in pain and that " her milk disagrees "; sometimes she volunteers that he has pain on micturition because he passes urine about the same time. The feeble or very young baby who is underfed, however, often shows no evidence of hunger, but becomes progressively more lethargic. The stools of the underfed baby may be infrequent or may be excessive in number, and typically are small and greenish brown, with excess of mucus, and sometimes looser than normal, though the quantity passed in twenty-four hours is always small; this distinguishes underfeeding stools from diarrhoea stools. Underfed babies are often brought to the doctor with a complaint of " diarrhoea "—and when in doubt one may have to treat the case as diarrhoea, with a preliminary starve, followed by a steady increase in food, on account of the risk involved in feeding a child who has enteritis. Occasionally vomiting is a symptom of underfeeding: the baby screams, and vomits apparently as a result; but, naturally, caution is necessary in attributing vomiting to underfeeding. Sometimes underfeeding results from inability to get the milk through the teat either because the hole is too small or because the teat is blocked by a badly mixed and lumpy feed, and in such cases one must beware of a history that the baby refuses his bottle.

If overfed the vigorous baby 4 weeks old and upwards usually gets rid of some of the food he does not require by vomiting after feeds, and shows no other symptoms. If, however, he is upset by the overfeeding (a much more frequent event in the bottle-fed than in the breast-fed, and in very young babies than in older ones) he will probably show evidence of discomfort, perhaps have a distended abdomen, and, besides vomiting, he will probably pass an excessive number of rather loose stools, the quantity in the twenty-four hours being also greater than normal. If upset the baby's normal increase in weight will be disturbed, sometimes seriously.

In practice it is common to find that a baby suffering from underfeeding has been diagnosed as overfed; when in doubt, estimation of the food intake is usually the quickest way of reaching the true diagnosis. If there are no facilities for carrying out test feeds the expression and measurement of the whole of one feed may indicate the diagnosis for a breast-fed baby.

Vitamin and Mineral Supplements.—The administration of a supplementary ration of vitamin D, vitamin C, and iron is advised for all babies—breast-fed and bottle-fed. At the present time with shortages of citrus fruits and fish-liver oils instruction is required as to possible substitutes. It seems that in Germany the Government is supplying vitamin D and ascorbic acid for all infants.

Alterations in Feeds

Upsets are often caused by sudden increases in the calorie intake, by sudden changes in the character of the feeds, or by sudden administration of a full dose of iron or even sometimes of cod-liver oil. Nurses and mothers should always be warned to increase food gradually; the average full-term baby, if hungry, can have an increase of, say, 1/2 oz. per feed at a time, and seldom more than 1 oz. increase per feed in a day. Changes from dairy milk or from dried milk containing iron to dried milk without iron; from full-cream to half-cream dried milk, or from any of these to sweetened condensed milk, can safely be made suddenly (provided there is no sudden change in the calorie value or volume of the feed), because ease of digestion increases in this order. Changes in the opposite direction require to be made gradually—e.g., directions to a mother for a change from a sweetened condensed milk feed to a feed of full-cream dried milk might be given as follows, four days being taken over the changes:

Days:	1st	2nd	3rd	4th		
Sweetened condensed milk	4	3	2	1	0 level teaspoonfuls	Four-hourly: 5 feeds in 24 hours
Full-cream dried milk	0	1	1½	2	3 " measures	
Sugar " "	0	0	½	1½	1½ " teaspoonfuls	
Water to " "	4	4	4	4	4 oz.	

For in-patient work the change over can be made by substituting, half to one ounce at a time, "standard" full-cream dried milk and sugar solution, for "standard" sweetened condensed milk mixture, again taking four days over the change as follows:

Days:	1st	2nd	3rd	4th		
Sweetened condensed milk, "standard"	4	3	2	1	0 fl. oz.	Four-hourly: 5 feeds in 24 hours
Full-cream dried milk, "standard"	0	1	1½	2	3 " "	
Sugar solution, "standard"	0	0	½	1	1 " "	

from aortitis in *acquired* syphilis. Further, the age incidence of thoracic aneurysm should be discussed.

Aortitis in Congenital Syphilis

Turnbull (1911) recorded two cases of syphilitic mesaortitis, the first in a girl aged 17 whose father suffered from a similar condition, and the second in a girl aged 7. At necropsy in both cases the macroscopic and microscopical descriptions were characteristic of syphilitic mesaortitis. There was no dilatation of the aorta. Clinically these patients did not show any of the stigmata of congenital syphilis, and the writer was not able to conclude that the lesions were of congenital origin. Heiman (1919) saw an aneurysm of the thoracic aorta in a boy aged 13 whose Wassermann reaction was strongly positive. This patient also had splenomegaly, and there was a suspicion of a gumma of the liver and Hutchinson's teeth. The mother had had two miscarriages and gave a positive Wassermann reaction. Stolkind (1920) after a careful survey of the literature could not find a single case of proved hereditary syphilitic aortitis in older children, and especially in adolescents and adults. Referring to a child aged 4 described by Willson (1914) as having an aneurysm, he stated that no process typical of syphilitic aortitis was found and that all the signs were inconclusive. Previtali and others (1930) in a series of 50 congenital syphilitics were unable to detect any evidence of aortic dilatation by clinical or radiological examinations. Givan (1930) failed to demonstrate syphilitic heart disease in 417 similar cases, whilst McCulloch (1930) concluded that congenital syphilis plays no part in cardiovascular disease in children up to the age of 15. McDonald (1932) described findings at necropsy in a boy aged 9 with congenital syphilitic mesaortitis whose father and mother were also syphilitics. The patient had interstitial keratitis and gave a positive Wassermann reaction. The aorta was examined microscopically, but no spirochaetes could be demonstrated. This writer concluded that definite clinical recognition of the condition is possible only in a few cases. Recently at the London Hospital 13 patients with congenital syphilis, whose ages ranged from 13 to 47, were examined clinically and by cardioscopy, and in none of them was there any evidence of aortitis.

It appears, therefore, that congenital mesaortitis can exist as a pathological lesion, but only rarely does it produce clinical or radiological evidence of an aneurysm.

The three cases described here do not belong to this group. In Cases I and II a history of primary infection was obtained; in the third case no stigmata of congenital syphilis were found, and the Wassermann reactions in both mother and sister were negative.

Onset of Aortitis in Acquired Syphilis

Sandford (1931) stated that in a series of 71 cases of thoracic aneurysm the average time interval between the initial lesion and the onset of symptoms was slightly over fifteen years. He found the shortest period between the primary sore and the earliest symptoms suggesting aneurysm to be two years and the longest fifty years. Coombs (1932) reviewed the literature and concluded that all observers were agreed that this interval was from fifteen to twenty-five years. Boyd (1924) studied 200 cases and gave this period as twenty years. Among 346 cases of cardiovascular syphilis Maynard and others (1935) found 190 in which the date of the primary lesion was known. About a quarter of these showed some evidence of cardiovascular disease within ten years, but the average for the series was twenty years. Evans (personal communication, 1935) examined 55 consecutive patients with acquired syphilis in whom the primary infection was known to be longer than five years. Examination was made clinically, electrocardiographically, and by cardioscopy. Aortic measurements were taken. Alteration in the aortic outline consequent on age or hypertension was considered when assessing the changes resulting from aortitis. In this series the aorta was judged to be normal in 25 patients and abnormal in 30. In 10 of the abnormals the aorta was altered as a result of hypertension or atheroma, and in 20 syphilis had produced the deformity. In relation to the primary infection aortitis was found in these 20 cases at intervals of 5 to 10 years in 1, 11 to 15 years in 4, 16 to 20 years in 5, 21 to 25 years in 4, 31 to 35 years in 4, 36 to 40 years in 1, and over 41 years in 1 case.

In the first two cases reported in this paper the interval between the primary lesion and the onset of symptoms was approximately 7½ years. In the third case the initial infection may have been acquired soon after puberty, and there is the possibility that the infection was extragenital and perhaps occurred in infancy.

It is clear that the usual latent period between the primary infection and the onset of cardiovascular symptoms in acquired syphilis is from fifteen to twenty years, but in a few cases the interval is less than ten years.

Age Incidence of Aneurysm

Many cases similar to those here described have been reported from time to time. As early as 1725 Morgagni (Kampmeier, 1938-9) did a post-mortem examination on a young woman aged 28. A small aneurysm was found half an inch above the aortic valve, which had ruptured into the pericardium. So exact is this first description of the morbid anatomical features of syphilitic aortitis that it merits recapitulation: ". . . that is to say, in some places whitish marks of a future ossification occurred; in others some small foramina, as it were, had begun to be formed; and in still other places were paralleled furrows drawn longitudinally—in this manner was the surface of the artery unequal here and there." In 1847 Crisp collected 12 cases under the age of 30. Le Boutillier (1903) reviewed the subject and discovered 18 cases under the age of 20 the aetiology of which was obscure. Richey (1923) after a detailed search of the literature found 41 cases under the age of 18, and remarked that only one of those presented definite evidence of syphilis. Brockbank (1925) analysed the records of 200 necropsies on cases of aortic aneurysm and found that 7.5% were between the ages of 21 and 31. Recently Kampmeier (1938-9) in a series of 633 cases of thoracic aneurysm found 9 (7 negro males; 1 white male; 1 negro female) under the age of 25.

Table showing Age and Sex Incidence in 840 Cases of Thoracic Aneurysm Admitted to the London Hospital 1893 to 1939

Age	Males	Females	Total
0–9	0	0	0
10–19	0	0	0
20–29	2	0	2
30–39	115	15	130
40–49	230	35	265
50–59	262	40	302
60–69	104	20	124
70–79	12	5	17
80–89	0	0	0

Authors vary as to the period of maximum age incidence of thoracic aneurysm. Lucke and Rea (1923) concluded that this period was 35 to 55, and Boyd (1924) from the investigation of 3,690 cases gave the age incidence as 36 to 40. Kampmeier (1935) stated that the highest incidence was between the ages of 45 and 55, and Cochems and Kemp (1937) in a study of 1,000 syphilitic individuals found 47 aneurysms, 39 of which occurred after the age of 50. The accompanying table compiled from the London Hospital in-patient records shows that the highest peak of incidence was

50 to 59, a somewhat higher figure than is commonly quoted. In this series it is of interest that no female patients with thoracic aneurysm were found under the age of 30.

Summary

Two cases of acquired syphilitic aneurysm in adults under the age of 30 are reported. It is probable that the disease was also acquired in the third case. Although congenital syphilitic mesaortitis does occur the incidence of aneurysmal dilatation is very rare. It is known that symptoms of thoracic aneurysm may appear within ten years of the primary syphilitic infection, but in the majority the period is fifteen to twenty years. As regards age incidence of aneurysm of the thoracic aorta, the maximum was found in the sixth decade.

My thanks are due to Dr. John Parkinson, physician to the cardiac department of the London Hospital, and to Dr. William Evans, the assistant physician, for their interest and advice; and also to the medical superintendent of Essex County Hospital, Wanstead, for his permission to publish Case III. The pathological description in Case II was kindly furnished by Prof. Hubert M. Turnbull.

NOTE ON THE TESTING OF TRANSFUSION FLUIDS FOR CONTAMINATION

BY

W. R. LOGAN, M.D., F.R.C.P.Ed.

Bacteriologist to the Royal Infirmary, Edinburgh

It is ideal that all bottles of plasma and of citrated blood used for transfusion should have been tested for sterility, but it is also ideal that no bottles should be opened before use. These ideals are in conflict. If each bottle is to be tested it is necessary that the ritual is such as to eliminate any possibility of contamination of the material in the course of the bacteriological examination.

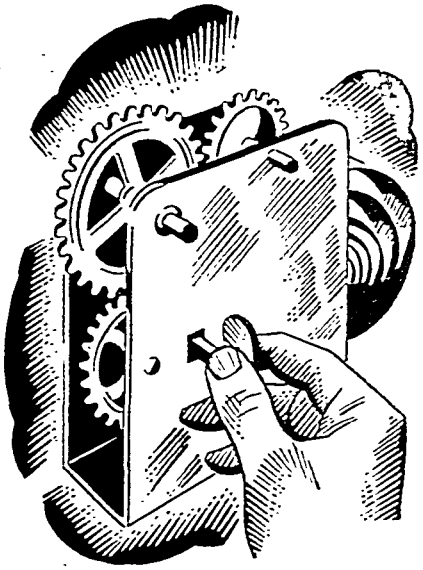
Technique

The technique used in this laboratory for the testing of transfusion material sent for this purpose from the Edinburgh Blood Bank is as follows.

All currents of air in the room are avoided. There is no speaking while the bottles are opened. No bottles are opened if anyone has recently sneezed or coughed near the bench. When a crate of, say, six bottles of plasma or blood is received, six tubes of ordinary or trypsin broth for aerobes and six tubes of Robertson's meat medium sealed with paraffin for anaerobes are set out in a rack and labelled. The cotton-wool plug in each tube is freed by turning, to ensure that it can later be removed with ease. The bottle is placed near to the rack and the rubber bung or screw cap removed with one hand while a Bunsen flame is played with the other on the upper rim of the bottle and air immediately above, into the upper inch or so of the aperture, and inside the screw cap or around the part of the bung which is to be inserted. The bung or cap is then replaced, but without ramming home or screwing down. A sterile Pasteur pipette is removed from the copper box in which it has been sterilized, a rubber teat affixed, and the part of the pipette which is to be introduced sterilized once more by passing through the Bunsen flame. The bung or cap is now momentarily removed and about 1 c.cm. of plasma or blood drawn into the pipette, the stopper being lightly replaced. Each culture tube in turn is then lifted between the thumb and ring and little fingers of the left hand, the cotton-wool plug is withdrawn between the index and middle fingers, the medium inoculated with half the pipetteful of fluid, and the plug replaced. In inoculating the anaerobic medium it is important that the pipette be withdrawn before all the fluid has been expelled, to avoid the introduction of air into the medium. The pipette is then discarded into a vessel containing antiseptic, and, with both hands now free, the bung or cap is again lifted and the ritual of flaming the lip and mouth of the bottle and the stopper carried through once more. Bung or cap is now screwed firmly home. All this takes only a few seconds.

The inoculation tubes are incubated at 37° C. for two days. If they remain perfectly clear the result is reported as negative. If there is any trace of turbidity, films and subcultures are made. Sometimes there is a slight change in the Robertson's medium which entails further examination when actually no organisms are present. It will be observed that while most varieties of organisms are catered for by the media used, which are enriched by the plasma or red cells introduced, there is no provision for the growth of haemophilic organisms when the material under examination is plasma. But as such organisms could not multiply in the original bottle of plasma even if accidentally introduced, it has not been thought necessary to use a blood medium.

Precautionary Measures



Strict injunctions are given that no one is to open a bottle except the person carrying out the examination. There is a very real danger here, as blood and plasma are both used in bacteriological laboratories for the preparation of media, and the latter for the coagulase test on staphylococci. If the Blood Bank gives an occasional present of blood to the examining laboratory it makes for additional safety in this respect. Where bottles have to be sent some distance to an outside laboratory it is advisable to seal them before sending, and before returning, in such a way as to make it obvious if they have been tampered with. Instructions are given to the messenger to shake bottles of blood as little as possible during transport.

Before being sent from the Blood Bank for testing, the bottles should be removed from the refrigerator and kept at room temperature for several days so as to give contaminations an opportunity of multiplying.

The technique above described has given satisfactory results, and can be carried through by one person. In no case, so far as can be ascertained, has it been the cause of contamination of a bottle, or failed to detect one when present.

The following notice appeared in the *New England Journal of Medicine* for February 27: "It will help England greatly in the care of victims of bombing raids and help England prepare for the coming invasion if physicians in this country all give discarded or superfluous surgical instruments or surgical dressings. Any such material should be sent to the Medical and Surgical Supply Committee, 420, Lexington Avenue, New York City."

Renewed DRIVING FORCE

Cardophylin brings about a rapid improvement in coronary and cerebral circulation, augments the blood output and stimulates the respiratory centre. It gives fresh vigour to the tired heart and promotes subjective amelioration with better resistance to depressive states. It is also a safe and useful non-mercurial diuretic.

Cardophylin is indicated in the treatment of Angina Pectoris, Cardiac Asthma, Myocardial Degeneration, Arterio-sclerosis, Cerebral Thrombosis, Bronchial Asthma, Œdema, etc.

In tablets, ampoules and suppositories.

Literature and samples on request.

Fungus infections of the skin

Infection of the skin by tricophyton ectothrix and epidermophyton inguinale is a common complaint, particularly in conditions such as the present, when large numbers of people have to live a communal life in the Services, in hospitals, and in A.R.P. At this time of year too, conditions favourable to a spread of the infection are multiplied by seasonal sources of increase, such as community bathing and athletics. The complaint is disabling, highly infectious, and effective treatment is of urgent importance.

Two products of Glaxo Laboratories are of specific value in these conditions

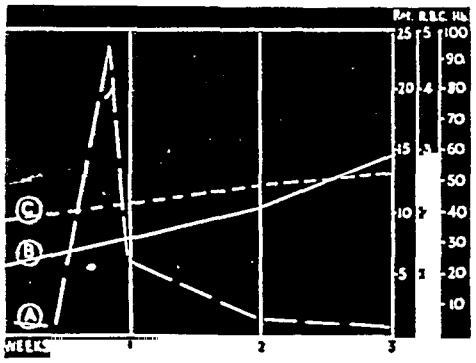
MERSAGEL

FUNGICIDE JELLY

A water soluble jelly containing phenyl mercuric acetate, an antiseptic of high fungicidal activity, and non-irritant to the skin. Application of Mersagel daily for from 3-7 days will rapidly clear up the infection. In 1½ oz. tubes.

PRODUCTS OF THE GLAXO LABORATORIES

DEROBIN



DI-OXY-ANTHRANOL

A synthetic chrysarobin analogue having 4-5 times the activity of chrysarobin. In ointments of from 4-10 grains to the ounce, Derobin is effective in clearing up the more chronic and resistant fungus skin infections. In 1 gram and 10 gram tubes.

Easing the burden of life-long treatment for Pernicious Anaemia

Examen Liver Extract provides the physician with the means not only of quickly restoring the patient's normal blood picture, but of securing the *most effective maintenance treatment with the minimum of discomfort and expense to the patient.* Each 2 cc. of Examen is derived from 100 gm. of fresh liver. Such concentration of the erythrocyte maturing factor maintains normal hæmopoiesis with small, widely spaced doses, e.g. 2 cc. every 3 to 5 weeks. The exceptional purity of Examen and its freedom from protein render injection painless and ensure absence of undesirable reactions.

A—Ret.—Reticulocytes (per cent. R.B.C.)
B—R.B.C.—Red blood corpuscles (millions per cmm.)
C—Hb.—Haemoglobin (per cent.)

The graph (an example of an actual case) indicates how Examen gives the required reticulocyte response, followed by a rapid regeneration of red blood corpuscles and the restoration of the hæmoglobin level.

Medical Memoranda

Unusual Dislocation of the Carpal Bones

It is thought that the following case is worthy of record owing to its unusual character.

CASE REPORT

A soldier aged 21 came to hospital on the morning of December 10, 1940, complaining of pain in his right wrist. Earlier that morning a lorry, whilst backing, had compressed his right hand and forearm against a wall. The elbow was flexed at the time so that the force was an impacting one, tending to drive the carpus proximally.

On examination there was considerable radial deviation of the wrist, and the lower end of the ulna was very prominent. Any attempt to move the wrist passively caused great pain.

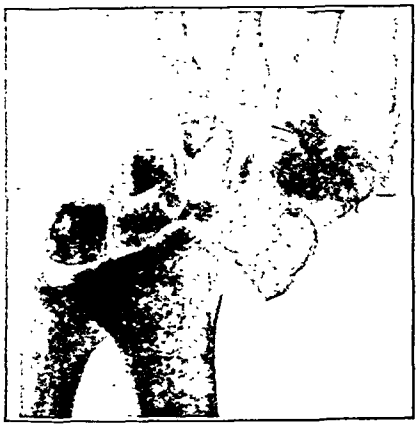

FIG. 1.—Radiograph showing gross dislocation of the carpal bones and fracture of the scaphoid.

A radiograph (Fig. 1) showed a gross dislocation of the carpal bones, with a fracture of the scaphoid. The only bones remaining in the correct anatomical position were the semilunar and the proximal third of the fractured scaphoid. The

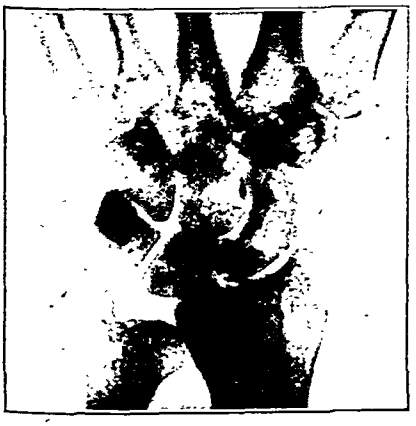

FIG. 2.—Radiograph showing the position after reduction.

others, including the distal two-thirds of the scaphoid, were displaced upwards, backwards, and towards the radial side of the wrist. The cuneiform was occupying the normal site of the scaphoid and was overlying the proximal fragment of the latter. Thus the appearance was that of a "trans-naviculo-perilunar dislocation" as described by Böhler (1935).

The dislocation was reduced under general anaesthesia. A calico bandage was passed round the arm for counteraction and the elbow was flexed to a right-angle. Strong traction was then exerted on the wrist for about ten to fifteen minutes; the carpal bones were also slightly manipulated. A second radiograph (Fig. 2) showed that the position after reduction was satisfactory. A volar plaster slab was then applied with the wrist dorsiflexed, and the patient was admitted to the fracture ward. A few days later a plaster bandage was applied to complete the plaster. He was discharged in plaster on December 23, his finger and thumb movements being very good.

On January 1, 1941, the plaster was removed and the wrist radiographed. It was thought that his scaphoid showed signs of commencing union, and he seemed to be doing very well. Another plaster was applied.

I wish to thank Mr. W. Harvey Gervis, surgeon in charge of the fracture clinic, Kent and Sussex Hospital, Tunbridge Wells, for permission to publish this case and for his help and advice.

LESLIE G. SCOTT, M.B., B.S.,

Lobectomy for Bronchiectasis in an Infant

The following report of a case of bronchiectasis in a young child treated by lobectomy has some features of interest.

CASE REPORT

The patient, a female child aged 19 months, was a twin weighing 4 lb. 5 oz. at birth; her twin brother weighed just over 5 lb. Up to the age of 6 months she was healthy, but remained under weight. She then developed a "cold" and ever since has coughed up offensive sputum which made her sick as many as five or six times a day. She had a chronic nasal discharge, was always listless, took little interest in her surroundings, and became pigeon-chested.

On examination the left lower lobe of the lung was seen to be the seat of the trouble. There was pronounced clubbing of the fingers and the temperature was raised and very irregular. The motions were offensive, and there was constipation. Owing to the poor condition of the child no bronchogram was taken, but postural treatment was tried, with little success, for two months. On September 12, 1940, a bronchogram showed considerable bronchiectasis of the left lower lobe, with large numbers of saccular dilatations. On November 16 the child was transferred to one of my beds at the Sheffield Royal Infirmary, and, after some pre-operative treatment, an operation was performed on November 21. A preliminary attempted artificial pneumothorax revealed that the lung was adherent, so that it was possible to perform the operation of lobectomy without further treatment.

The chest was opened by the usual incision in the sixth intercostal space and the lung separated from the thoracic wall. The roof was defined and clamped with a tourniquet, and the lung removed. The cavity left was drained under "automatic suction" drainage. There were no post-operative complications, and on December 9 the child was sent back to the Children's Hospital to complete her convalescence.

Pathological examination of the excised lung showed extensive saccular bronchiectasis, the cavities for the most part being filled with pus. It is probable that the lobe was of the congenital cystic variety and became infected at the age of 6 months. As the lipiodol did not fill the upper lobe it is not possible to say whether there were saccular dilatations in it or not.

After her return to the Children's Hospital she developed chicken-pox, and shortly after recovering from this she had measles, but in spite of all her troubles she was very well when seen at the end of January, 1941. She was then quite a different child; she played with toys, was cheerful, and had a good appetite and a good colour.

I am unaware of any case in which a lobectomy has been performed at such an early age, though I expect there are some.

Sheffield. A. W. FAWCETT, F.R.C.S.

Reviews

RADIOLOGY OF HEAD AND NECK

The Head and Neck in Roentgen Diagnosis. By Henry K. Pancoast, M.D., Eugene P. Pendergrass, M.D., and J. Parsons Schaeffer, M.D., Ph.D. (Pp. 976; 1,251 illustrations. 69s.) London: Baillière, Tindall and Cox.

To ensure that the criticisms which follow are read in proper perspective, let it first be stated that *The Head and Neck in Roentgen Diagnosis*, by such a distinguished team as H K. Pancoast, E. P. Pendergrass, and J. P. Schaeffer, is a book of first importance to radiologists. It is a large book, of 976 pages and 1,251 illustrations, and, as may be deduced from its title, is designed in unusual form. This arbitrary division of the subject through the root of the neck leads to some difficulties. For instance, in many bone diseases the authors are driven beyond the limits imposed by the title in order to give a reasonable description of the condition as a whole. Again, the upper part of the trachea and oesophagus and the lung apices fall within the ambit of the book, but not the superior mediastinum or the rest of the lungs. This format has, however, one great advantage. It presents, collected in one volume, a mass of information for reference in cases in which the lesion is manifestly located in the head or neck.

In the preface the authors state their aim to be to correlate radiology "with the apposite facts in developmental and adult morphology, physiology, pathology, and observations in clinical medicine and surgery and the special branches." The turgidity of this phrase can be matched by much of the writing of the book. Indeed, throughout the whole book there is a prolixity that makes the reader long for the use of the terse phrase and the simple word. One feature that will strike him is the detailed nature of the anatomical descriptions. Often these are of the greatest value, and give data not readily available elsewhere. Here and there they are redundant, as on page 22—"From each alveolus, projecting downwards, are the upper teeth. In apposition with the upper teeth are the lower teeth, which project upwards from the alveolar process of the mandible." Again, on page 55, "The oral cavity is largely obscured by the teeth, which project downwards and upwards from the upper and lower jaws respectively." Resolute pruning would reduce the size of a second edition and add to its usefulness.

The first four chapters deal with the anatomy of the skull, fractures and other bone lesions, and tumours of the scalp, skull, and spine. These are generally excellent, but one or two minor points might be corrected—for example, the term "desiccation necrosis" on page 165 (dissecting necrosis?), and the statement that Ewing's tumour of long bones has no characteristic *x*-ray appearance. The term "increased radiability" on page 267 is not a happy one. The section on the teeth is very good, and especially the anatomical description. The chapters on the nose, lacrimal apparatus, sinuses, and temporal bones occupy 170 pages and are particularly well done. The description of intracranial tumours and cerebral pneumography takes up 230 pages, and is the most important section of the book. It is an admirably complete account of the subject. The last section, on the neck, deals with such varied subjects as the pharynx, larynx, trachea, oesophagus, cervical pleura, the thyroid and other glands, and, finally, the cervical part of the spinal cord.

In conclusion, there is a wealth of information in these pages, and as a book of reference it is invaluable. The authors deserve congratulation on producing a work of outstanding merit, and one which is recommended to all diagnostic radiologists.

ADVANCES IN FOOD-CANNING

Canning Practice and Control. By Osman Jones, F.I.C., and T. W. Jones, B.Sc. Second edition. Revised and enlarged. (Pp. 312. 32s. net.) London: Chapman and Hall, Ltd. 1941.

The second edition of *Canning Practice and Control*, by O. and T. W. Jones, which appears within three years of the first, has been enlarged to keep pace with recent advances. One of these is "high short" processing, in which high temperatures are applied for short periods. According to the heat penetrability of the food treated the periods may range from a few seconds upwards. The shorter the time the better is the quality of the finished article. Fruit juices can be flash-pasteurized at lower temperatures than most foods, since the bacteria which they contain are feebly heat-resistant. A new chapter is devoted to the packing of foods in glass. The heavy-calibre glassware necessary is subject to stresses during heating. Faults in fresh consignments may be thrown into prominence by means of a "strain-viewer," using polarized light. Specially annealed glass is relatively heat-proof, but the general tendency in the processing of foodstuffs put up in glass is to employ a moderate temperature and give a longer exposure. Another new section is that upon the thermophilic bacteria. It is said that these organisms are less likely to cause spoilage in foods canned for the home market than in those exported to the Tropics, the reason being that home air temperatures are seldom high enough to favour the vegetative development of thermophil spores. It is believed that sugar and starch are the principal vehicles for the introduction of these germs into canning factories. The book is handsomely produced and copiously illustrated. It is, like its predecessor, a valuable and instructive guide to the principles and procedure of the important industry with which it deals.

SKIN HYPERSENSITIVENESS

Dermatologic Allergy. An Introduction in the Form of a Series of Lectures. By Marion B. Sulzberger, M.D. (Pp. 540; 13 colour plates, 39 illustrations. 47s. or $8.50 post paid.) Springfield and Baltimore: Charles C. Thomas; London: Baillière, Tindall and Cox. 1940.

Dr. Sulzberger is certainly one of the most prolific and industrious writers on dermatology at the present time. No fewer than three fat volumes are credited to him (it is true not without collaborators) within a single year, and the one now before us is the fattest. This is not surprising in view of the immense field included in the term "allergy." It may not be generally remembered that the word was originally coined by von Pirquet in 1906 to express the phenomena of hypersensitiveness in animals artificially immunized against various diseases, and Sulzberger has done a service to the modern generation by reprinting in this book a translation of von Pirquet's original paper. But the applications of the term have gradually been extended, and the present author defines it as any specific alteration in the capacity to react which occurs in living organisms or tissues upon exposure to either living or inanimate agents or substances. Hence there is exceedingly little difference between allergy and hypersensitiveness, and we are still unable to understand why it was necessary to coin this new word. Sulzberger thinks differently, but we do not think he puts up a very strong case.

However, the term "allergy" has undoubtedly established itself and has come to stay. It will be seen that in its comprehensive sense it includes pretty well every manifestation or symptom of disease which can be found on the skin. Not only are serum eruptions and urticarial rashes to be regarded as manifestations of allergy, but all the

exanthemata, the rashes of syphilis, the various forms of tuberculous disease, drug eruptions, and in fact every variety of skin eruption for which the proximate cause or agent is known is described as allergic to that agent. So the chief skin diseases which are not yet included among the allergic states are psoriasis and lichen planus, simply because we do not know their aetiology; and, when we do, no doubt they too will be considered as manifestations of allergy. There is therefore no reason to be surprised at the size of Sulzberger's treatise on the subject, and we haste to add that it is a mine of information. There is also a chapter on the future probable or possible developments of the subject. He thinks that improvements in present methods may lead to specific prophylactic measures in many diseases with the same success that has already been attained in small-pox and diphtheria, also that non-specific measures may help by preventing the occurrence of damaging forms of specific reactions by fortifying the constitutional defences by all sorts of different means, such as diet, elimination of septic foci, administration of hormones, regulation of electrolytes, etc. In other words, he thinks that there is a great future for preventive measures in medicine. We fancy that the same conclusion might have been arrived at more simply.

Perhaps the chief value of this book is that it gives so full a summary of all the work that has been done on skin-hypersensitiveness for the last thirty years, and the classificatory tables and lists of tests and of various antigens will be found most useful. Like most American publications, the book is excellently got up and the printing, paper, and illustrations are above reproach.

CHEMOTHERAPY OF BACTERIAL INFECTIONS

Essentials of Modern Chemotherapy. By Various Authors. Edited by Sir Humphry Rolleston, Bt., G.C.V.O., M.D., F.R.C.P., and Alan A. Moncrieff, M.D., F.R.C.P. "The Practitioner" Booklets. (Pp. 104. 6s.) Published by "The Practitioner" in conjunction with Eyre and Spottiswoode, Ltd.

A series of papers which appeared in the *Practitioner* in January, 1940, on treatment with sulphonamide compounds has now been published in the form of a small book entitled *Essentials of Modern Chemotherapy*, a somewhat more comprehensive title than its contents justify, since it deals with no other forms of chemotherapy than those recently introduced for the treatment of bacterial infections. The authors of these papers have revised them in the light of fresh knowledge acquired during the past year, and they afford a useful practical guide to the treatment of streptococcal, pneumococcal, gonococcal, and meningococcal infections. There is also a chapter on chemotherapy in the acute specific fevers and a new one on the use of sulphathiazole in staphylococcal infections. In a work so arranged, and of comparatively small size, other and less generally familiar aspects of the subject are naturally less fully dealt with; the treatment of gas gangrene and the local application of sulphonamides to wounds, for instance, are mentioned only in an appendix which briefly conveys the instructions on these subjects issued in official memoranda since the outbreak of war. A chapter on the treatment of urinary infections might usefully be added in any future edition.

Notes on Books

Professor WILLIAM BOYD'S *Pathology of Internal Diseases*, the third edition of which has appeared (Henry Kimpton, 30s.), is a deservedly popular book, attractive by reason of both its lavish illustration and engaging style. The picturesque touch is freely used to interest the student and leave a vivid impression on his mind: this is achieved both by choice of language and by the citation of extreme cases, such as the silicotic lung which had to be cut with a saw. Many subjects have been rewritten in this edition or discussed for the first time. These changes as a whole add much to the value of the book, although individually some of them occupy little space; extrarenal uraemia for instance, makes its appearance with a paragraph of only eight lines, which might well be amplified considerably. The close relation between pathology and clinical medicine for which the author has always striven is maintained not only throughout the text but by numerous photographs of patients, illustrating such features of disease as deformities of various kinds and abnormal gaits.

The innovations in the third edition of L. C. PETER'S book on *Extra-ocular Muscles* largely concern orthoptic training the scope of which a cautious but useful assessment is given. The chapter on nystagmus has been expanded, but still remains a rather confusing mass of isolated details. The book is published by Henry Kimpton at 21s.

Preparations and Appliances

EFFICIENT SULPHANILAMIDE INSUFFLATION

Mr. A. R. HODGSON writes from the Norfolk and Norwich Hospital:

In the treatment of compound fractures and extensive muscle lacerations, few can doubt that the use of sulphanilamide powder locally prevents much sepsis. Of the methods of applying the powder, opinion is unanimous that insufflation is the best. It ensures an even film of powder over the damaged tissues, resulting in maximum adsorption and thorough penetration.

In the Orthopaedic Department here we have been using the Evans Sons Lescher and Webb insufflator, which gives a very fine and intermittent spray. This spray has been found to be too fine, and not of sufficient penetrative power for compound fractures and severe muscle lacerations. A far greater, and if possible continuous, positive pressure is needed to produce an adequate flow of sulphanilamide powder.

This has been achieved by using an oxygen or carbon dioxide cylinder as a source of positive pressure. The apparatus is fitted up as follows. A four-foot length of pressure rubber tubing is connected up from the cylinder to the insufflator. A cylinder with both fine and coarse adjustments should be used. A further length of sterile rubber pressure tubing is fitted from the insufflator to the wound; generally about nine feet is sufficient. A glass nozzle may be fitted to the free end of the sterile tubing. The coarse adjustment of the cylinder is turned on. The fine adjustment is then turned on slowly until a fine spray is obtained. The nozzle is now turned towards the wound and held about two inches from it. The sulphanilamide powder forms a "frost" over the damaged tissues. When all the wound is covered by this "frost" of powder the cylinder is turned off. The positive pressure can be regulated, giving a variable sulphanilamide spray with varying penetrative power. This method has been found to be both simple and effective by those who have used it.

No toxic manifestations of any severity have been observed from the local application of sulphanilamide. Amounts far in excess of the recommended dose of 15 grammes have been given with no ill effects. In some cases of severe multiple injuries doses of 50 to 60 grammes have been given. The dose is that amount needed to cover the injured tissues with a "frost" of powder. When large amounts are used the breath has an odour of garlic. Slight cyanosis may occur with massive doses. In only two cases have I seen a sulphonamide rash; they were both having 1 gramme sulphanilamide orally, four-hourly, in addition. The rash disappeared within forty-eight hours of stopping the oral sulphanilamide. No case showed a pathological decrease of the white blood cell count.

Care should be taken when insufflating small penetrating wounds, such as those due to bomb fragments. Excessive pressure will strip the superficial fascia from the deep fascia, and balloon up the skin. No harm has come from the introduction of either oxygen or carbon dioxide into the wounds: they may have a beneficial effect.

BRITISH MEDICAL JOURNAL

DYSPEPSIA AND CARDIOVASCULAR NEUROSES IN WARTIME

This war has so far produced no new diseases and the number of physical and psychological casualties from total warfare has been far smaller than was anticipated. The two disorders which have attracted most attention are peptic ulcer and effort syndrome, and here there has been no change in incidence and severity, but merely a shift in outlook and perspective. The physician who has been so fortunate as to work at a hospital which serves a fair sample of the population, and which has the resources to investigate its cases fully, knows that peptic ulcer is a common cause of dyspepsia. The pathologist of such an institution finds not only the scars of ulcers but unhealed craters in a surprisingly high proportion of subjects whose notes in many cases bear no record of treatment for indigestion. When men suffer from peptic ulcer in civil life they are enabled to carry on by readjustments of diet and by occasional periods off work, which in cases of declared ulcer average about a month every year. Such forms of adaptation are rarely compatible with combatant service, and the presence of an ulcer therefore means the rejection or discharge of a man from the fighting Services unless he is possessed of very special experience or gifts to outweigh his disability. The physician trained in civil practice has been slower to recognize a type of dyspepsia, familiar to the Army doctor, which occurs in young men who pass abruptly from a sedentary to a strenuous existence and suddenly double or treble their food intake. This is a transient disturbance, comparable with the belly-ache of the school-boy who overeats, and it is in the highest degree undesirable that such patients should be submitted to a full-dress gastro-enterological investigation. Such a practice is known to create invalids, whereas the dyspepsia can be simply relieved by a few words of advice and reassurance. There is therefore nothing very mysterious or specific to this war in dyspepsia in soldiers, and the most important conclusion to be drawn is that our facilities for the diagnosis of ulcer in peacetime and our methods of treatment are still very unsatisfactory.

The physician in hospital practice in civil life has also been seeing in recent years an increasing number of patients, mainly females, who are referred for investigation on a suspicion of thyrotoxicosis, which proves not to be present. These cases, according to the order of presentation of symptoms and his individual bias, he diagnoses as cardiovascular neurosis, neuro-circulatory asthenia, vasomotor instability, or anxiety state. Spence[1] pointed out that, although such patients show tachycardia, the sleeping pulse rate may be normal, the typical exophthalmos, tremor, and fidgetiness of Graves's disease are absent, and there is often a history of nervous breakdowns in the past or of having always been delicate; the symptoms may have been precipitated by a period of mental stress, anxiety, or overwork. The cardiologist, too, knows these patients well, and Bourne[2] described a group of them, in whom the presenting symptom was inframammary pain, under the somewhat unfortunate title of "angina innocens" in our columns a few years ago. Bourne pointed out that the pain differs from that of organic heart disease not only in its location but in several other characteristics. The pain has no quantitative relation to exercise and is chiefly noticed after the exertion has ceased, when it may persist for some hours. It can also be produced or accentuated by excitement, and in a few cases it is followed by a feeling of faintness or actual fainting. When the presenting symptom is dyspnoea on exertion the disturbance is referred to as effort syndrome. Paul Wood,[3] whose Goulstonian lectures we have had the privilege of publishing, disagrees with this name on the ground that the symptoms are those of fear and anxiety, not of effort, and he uses the eponymic diagnosis of Da Costa's syndrome. We would prefer to follow the Standard Classified Nomenclature of Disease and include the various conditions mentioned under the comprehensive title of "cardiovascular neurosis." Whatever the divergence in nomenclature, there is general agreement about the facts, and our knowledge is not only ably reviewed but also extended and systematized in Paul Wood's lectures.

Cardiovascular neurosis is not a wartime disease, and it is more common in females than in males. It becomes apparently more frequent in wartime because sufferers tend to seek a sheltered existence, and it is only when they are called upon to bear the full heat and burden of the day that they become casualties. Wood believes that the condition arises when the emotion of fear becomes attached to the idea of exertion. A boy's first symptoms may occur during a game of football, when he is afraid of bodily hurt, and subsequent exertion evokes the same symptoms of dyspnoea, palpitation, and prostration to which this first fear gave rise. The fears and the symptoms are often perpetuated by the parents. It is as disastrous for a child to grow up in a neurotic home as in a tuberculous one, and a good deal might be said in favour of a Grancher system to protect children from the familial contagion of neurosis. The psychological background of effort syndrome has been explored by Wittkower, Rodger, and Wilson,[4] who believe that in all cases the syndrome is antedated by a character disorder. A fairly high proportion of their patients were over-conscientious and over-scrupulous, qualities which had made them useful members of the community in peacetime, but there was a general lack of toughness and joy in living which ill fitted them for the rigours of camp life and the battlefield. Among precipitating factors emotional disturbances were commonest and were of a type to which the patient had been previously sensitized. Other factors were over-exertion and febrile illness, most commonly a respiratory infection. Caughey[5] has emphasized the importance of convalescence from acute illness in the

development of psychosomatic disorders. In addition to the physical effects of the disease process and the inherent recuperative powers of the organism, the convalescent period is complicated by the subconscious effects of the care and attention lavished upon the sick person, and the problem of his real desire to return to an active struggle against the forces of his environment. In the last war Bridgman[3] made careful estimations of the time required after various illnesses before the soldier was fit for full military duty. The average interval was 31 days after influenza, 34 days after tonsillitis, 58 days after pneumonia, 77 days after scarlet fever, and 50 days after herniotomy. These are much longer periods than the average medical practitioner would probably have suggested, and they emphasize the importance of intelligent medical supervision and military discipline if the soldier is to be completely cured and returned to the fighting line as promptly as possible. The physician must both realize the need for a period of rehabilitation and at the same time take pains to avoid any suggestion of cardiac disease.

The diagnosis of effort syndrome is based on the frequent occurrence of neurosis in the family history and previous history, and the characteristic symptoms of breathlessness, palpitations, fatigue, sweats, nervousness, dizziness, and left thoracic pain. Important signs are the anxious appearance, the cold blue hands, the instability of the pulse, blood pressure, and respiration, the inability to hold the breath, the sweating on the palms, and the poor physical development and asthenic posture. Symptoms are rarely if ever confined to exertion. They may occur at any time of the day or night and they are invariably evoked by emotion. Moreover, the individual symptoms are unlike those of heart disease. The dyspnoea is a rapid shallow breathing or inability to obtain a satisfying breath, and the sweating is confined to the palms of the hands and the axillae. Paul Wood has made an experimental study of the inframammary pain and produces good evidence that it arises in the muscular or fibrous tissues there, most commonly as a result of fatigue or strain of the respiratory muscles from the disordered breathing; a number of additional factors determine its localization to the left side. Secondary constellations of symptoms may group themselves around the main symptom-complex, and the hyperventilation syndrome is not uncommonly observed. In differential diagnosis it is to be remembered that a cardiovascular neurosis may be superimposed on an organic lesion of the heart, such as early mitral stenosis, which in itself should be symptomless. The prognosis depends largely on the personal and family history and the number of abnormal signs present; in any event it is poor. Few men with a personal and family history of neurosis or effort syndrome will make good soldiers, and, like those with a history of peptic ulcer, they should not be enlisted. Nevertheless the syndrome can be induced in adult life, and the battalion medical officer must be watchful to nip such cases in the bud. When a man complains of cardiac symptoms due to excitement, terror, or suppressed emotion, the medical officer must have the courage to say explicitly that there is no cardiac disease and the symptoms are natural and transient emotional responses. Some of the younger medical officers who come straight from hospital show a regrettable inability to take a careful family and personal history or to make a clinical diagnosis without a second opinion or elaborate special investigations. The place to prevent psychological casualties is in the front line, and the methods are those of general practice rather than the hospital ward.

THE A.M.A. CONSPIRACY TRIAL

The long trial for conspiracy of the American Medical Association, along with certain other medical bodies and eighteen responsible officials, ended on April 4 with the somewhat illogical verdict of "Guilty" against the A.M.A. and three other bodies, and "Not Guilty" against the individuals. A Federal statute called the Sherman Act prohibits combinations or conspiracies in restraint of trade in the District of Columbia. Strangely enough, for the purpose of this Act the practice of medicine is trade, but carpentry and by inference, other industries are not. A company called "Group Health Association Incorporated" was formed to provide medical services on a flat-rate prepayment basis, employing salaried practitioners. The policy of the A.M.A. is that doctors should be paid fees for service. Accordingly the Association and certain other bodies connected or in sympathy with it organized a campaign against the Group Health company. In the course of this they threatened such of their members as should become members of the staff of Group Health, or who should consult with members of its staff, with disciplinary action: and induced hospitals to deny facilities to medical practitioners employed by Group Health. The United States Government prosecuted them under the Sherman Act, alleging that their campaign constituted a criminal conspiracy.

As Associate-Justice James M. Proctor explained to the jury in his summing-up,[1] a conspiracy is committed when two or more persons combine to do an unlawful thing, or to do a lawful thing by unlawful means. It is not essential that all details of the plan be specifically arranged, or that the particular acts of each conspirator be definitely assigned; it is enough if there has been a meeting of minds for concerted action to gain the common end. All need not know each other or meet together at any one time, nor need all combine at the start of the conspiracy. Membership of the defendant medical societies, presence at their meetings, or knowledge of an unlawful plan would not alone make a person a participant: he must also have a positive intention to give adherence and support to the criminal scheme. The case for the Government was, he said, that the medical societies were opposed to Group Health and its plan, that they feared competition by the fixed-prepayment method of practice as against the free-for-service method, and that to obstruct and destroy such competition they conspired to impose restraints on medical practitioners affiliated with Group Health by threats of expulsion, by denying them professional contacts and consultations with other practitioners, and that the medical societies were opposed to Group Health doctors facilities for treating their patients. This plan, the prosecution said, was carried out by enforcing compliance with a statement known as the Mundt resolu-

[1] *J. Amer. med. Ass.*, April 12, 1941, p. 1760.

tion of the A.M.A. (which set out the position, the Association's attitude towards it, and the methods proposed to deal with it), implemented by a "white list" and aided by corporate and individual acts of the defendants. On the other hand, the defendants contended that there was no purpose or plan to restrain Group Health, the hospitals or doctors; that their acts were intended only to oppose Group Health by legitimate argument and persuasion; that no coercion was practised or intended against the hospitals; and that the "white list" and disciplinary proceedings against members represented reasonable action taken by authority to protect the organization and its standards of medical practice; and that if those actions interfered with Group Health and its doctors the effect was an incidental and indirect result of acts done legally and in good faith for legitimate ends.

The learned judge pointed out that reasonable discipline and control of members of a society are essential, but they cannot be justified where the real purpose or the natural results of their exercise are to interfere with free competition. Refusal to consult with particular physicians is not in itself illegal, but it may be illegal if done in furtherance of a conspiracy. A doctor may refuse to treat patients in a particular hospital, but if a group of doctors carrying out a concerted scheme refused to treat patients in order to injure the business of the hospital they would act illegally. The defendants were not entitled to oppose Group Health in a manner intended to restrain its operation, but they had the right of legitimate criticism, argument, and persuasion, however persistent and severe, either separately or by collective effort; if such opposition did not take the form of a conspiracy to restrain, it did not violate the statute. Similarly, the "white list" and the Mundt resolution were not wrongful in themselves, but only if perverted to advance the aims of a conspiracy. The same law applies to the action of hospitals in withholding privileges from certain practitioners.

The conviction of the corporations with the acquittal of the individual members directing them has naturally puzzled critics throughout the whole of the United States, and possibly elsewhere. In this country a corporation cannot be charged with a crime, and such a prosecution would have had to be brought only against individuals. The acts alleged against the defendants in this case could not be made the basis of a criminal prosecution here, though they might form ground for a civil action. The history of the British Medical Association does in fact contain, a generation ago, a civil action of this kind. However inconsistent the decision of the American jury may appear, it seems to have decided practical advantages. The *Washington Post* remarks (April 6) that the effect of the verdict is to stop the A.M.A. and the associated societies from interfering with the Group Health Association or other group practice enterprises which may fill a social need in present times. On the other hand, the verdict leaves no reflection upon the well-known medical practitioners and officials who were indicted for conspiracy, and recognizes that they had no intention of acting illegally. The finding may yet be reversed on appeal, and so the position cannot now be regarded as settled. The Sherman Law may possibly have to be reconsidered before the case is finally decided.

DESTRUCTION AT THE ROYAL COLLEGE OF SURGEONS

We are glad to supplement last week's article published at page 830 under the above heading and make certain corrections. Much further information is now available which the medical profession will wish to have at the earliest moment. With regard to the pictures and the Library, which were scarcely mentioned in our report, all the College portraits, except a very few having little artistic or historical interest, were sent away before the outbreak of war. Nearly 90,000 volumes from the Library have been sent to various parts of the country, the transfer being aided by a generous grant from the Rockefeller Foundation. The only books now standing on the shelves are standard textbooks; these and some current periodicals have been kept for reference. The principal treasures of the Library had been sent away before the outbreak of war, and none of the books remaining at Lincoln's Inn Fields has suffered damage in air raids. In addition to the specimens which were reported last week as safe, we are happy to learn of many others that escaped. The basement of the College covers a very wide area, and not more than one-fifth of it was involved in the fire. Many rooms and a number of cellars in which specimens were placed for safety were unaffected. The more important specimens had been taken to a tunnel below the basement and surrounded by sand; others were placed in branches from this tunnel. Some of the tunnels, already very strong, had been specially reinforced. All the specimens in the main tunnel and the majority of those in the branches were saved from destruction. The important College records and historical documents had been sent away. Only the working records dealing with the distribution of those specimens which had been placed in the basement and sub-basement for safety, and the records of pathological specimens presented to the College during the last few years, were destroyed. The preservation of copies of the Museum catalogues had been carefully considered and appropriate steps taken. All were saved with the exception of the catalogue of part of the Pathological Section, and that of the Curio Room, but nearly all of the specimens in this room are described in the "Guide to Surgical Instruments and Objects in the Historical Series." No fewer than 3,750 of the Hunterian specimens which are safe have already been catalogued, and it is expected that this number will be increased. The original Gibraltar fossil cranium is safe; and while much of the teratological collection was lost, the major part of the collection, consisting of 950 specimens, has been saved. Ninety-five specimens, or rather more than one-third, of the Onodi collection are safe. The greater part of the large collection of instruments is also safe and can be restored. Among the instruments that are intact are the Lister, the Moynihan, and the Chinese and Japanese collections; also the series illustrating the evolution of anaesthetic apparatus.

Thus, though the loss that the Museum has suffered is grievous, and much of it is irreplaceable, the destruction of specimens is not quite so great as was at first feared. Enough has been saved to form the basis of the new Museum, which will continue the Hunterian tradition.

NEW SULPHONAMIDE COMPOUNDS

A series of reports from the United States shows that rapid progress is being made there in synthesizing and testing new sulphonamide compounds. We have already referred in this *Journal* to sulphadiazine (2-sulphanilamidopyrimidine), a drug with properties which at least in the pharmacological sense represent an immense advance. These are fully confirmed in a careful study of its absorp-

tion, distribution, and excretion by O. L. Petersen *et al.*[1] Higher blood levels are attained with this drug than with any other sulphonamide compound, and sustained longer, so that it evidently need not be given more often than six-hourly. The concentration in the blood plasma exceeds that in the blood cells, an advantage shared with sulphathiazole; on the other hand, where sulphathiazole is at some disadvantage—namely, in reaching the cerebro-spinal fluid in a concentration only one-third of that in the blood—sulphadiazine resembles sulphanilamide and sulphapyridine in attaining a concentration two-thirds of the blood level. Conjugation is slight and not progressive the acetyl compound being readily excreted. More welcome to patients themselves than any of these properties will be the fact that this drug does not cause nausea or even mental depression. It is known to be active against all the chief infections amenable to sulphonamide treatment, but comparative studies of therapeutic efficacy have yet to be made.

Two other new compounds have made their appearance in America, neither of which seems at first sight to have such outstanding properties as sulphadiazine, although each has its interesting points. "Promin" is the name given to the sodium salt of *p.p'*-diamino-diphenyl-sulfone-*N.N'*-dextrose sulphonate, and a series of papers by J. A. Toomey and his colleagues[2] records some preliminary clinical trials with it. This drug is best given intravenously in 5-gramme doses thrice daily; oral administration is said to cause more toxic effects, and to have also the disadvantage of irregular absorption. It appears from these studies only that the drug is reasonably well tolerated and has an action comparable with that of sulphanilamide on streptococcal infections. A more remarkable action is illustrated in the work of W. H. Feldman *et al.*[3] on experimental tuberculosis in the guinea-pig. The drug was here fed to the animals with no apparent difficulty or ill effect, and seems to have retarded the progress of the disease after inoculation with virulent tubercle bacilli in a very striking way, but the experiment was complicated by intercurrent infection and needs to be repeated. It was shown some years ago by Rich that large doses of sulphanilamide retarded the development of tuberculosis in the guinea-pig to some extent, but the effect achieved here was evidently greater.

A third new compound on trial in America is sulphanilylguanidine, which has quite different properties and uses. Owing to its low degree of solubility and slow absorption, it is possible, as E. K. Marshall *et al.*[4] have now shown, to maintain saturation of the intestinal contents with the drug, while the blood concentration remains low. It has accordingly been used, and with some success, in the treatment of bacillary dysentery. This is perhaps not quite as hopeful a sphere of action as, for instance, the urinary tract, but anything with a specific local effect on intestinal infections, even if less sure and speedy than what we can now see elsewhere in the body, will be a welcome innovation.

EMPLOYMENT OF WOMEN IN INDUSTRY

The medical problems, many of them with a sociological bearing, which have been created or intensified by the recent entrance of large numbers of women into industry were debated at a meeting of the Association of Industrial Medical Officers held recently in London. Dr. M. L. Dobbie-Bateman, in opening the discussion, based her remarks on the sickness records for the five years 1935-9 of a group of about 6,000 people employed in a retail distributive house, the sexes almost equally represented. The average annual number of days lost through sickness for each male worker was 4.01 and for each female worker 6.36. An analysis of the conditions which caused sickness showed in respect of diseases of the genital organs a 500% excess among females over males, but the total number of days lost in this group was so small as to be almost statistically negligible, being only 0.24 out of 6.36 for the female worker, and 0.04 out of 4.01 for the male. The same applied to the 200% excess amongst female workers on account of dental disease. Respiratory diseases accounted for just about half the total of sick absenteeism, and here the female excess over the male was 75%. Only in respect of diseases of the locomotor system and of accidents were the male figures in excess of the female. Dr. Dobbie-Bateman's conclusion was that there was a consistently higher sickness rate among women employed in industry, that gynaecological conditions did not entirely explain the excess, and that a large part of the female disability was due to the fact that the working woman tried to do two things at once—to earn her living and to be responsible for her household duties. Miss F. I. Taylor, Deputy Chief Inspector of Factories, said that in peacetime the women working in factories were mostly young; the average life of a woman in a factory was reckoned at ten years, from school-leaving age until 24, but now there was a tendency for older and married women to be employed. One important consideration was the hours of employment. Peacetime restrictions in this respect could not be maintained, and longer hours were being worked than those concerned with factory welfare could approve, but, generally speaking, an endeavour was made to keep the working week below 60 hours and to ensure that every woman had one day off in seven or two in fourteen. A return from 5,000 factories showed that nearly half of them were working over 56 hours but under 60. The disadvantage of over-long hours was illustrated by the experience of a factory which had been working 54 hours and found it impossible to maintain production until every third week the hours were reduced to 48. Dr. L. S. Swanston, medical officer at one of the new ordnance factories, mentioned that the incidence of rejection on medical grounds among women applicants for employment was only 7% to 8%; on the other hand, the standard was not high. In her own department, during 1940, 52 women reported pregnant. As soon as this happened the woman was taken off night shifts and overtime, put on sedentary work, and examined every fortnight. She remained at work until the seventh month and was allowed to resume work one month after confinement. In the subsequent discussion it was urged by more than one speaker that women should not be allowed to continue until as late as the seventh month, and that to resume one month after confinement was far too soon, having in view the health not only of the mother but of the child. Dr. Swanston wanted to see the factory medical service extended to include ophthalmic and dental treatment; the amount of dental sepsis she had seen among these girls was astonishing. She also urged the appointment of a panel consultant in each district upon whom the factory medical officer could call in difficult cases. Dr. Graves Peirce described the work of women on the railways, which in peacetime is chiefly clerical or canteen, but now embraces many unfamiliar roles—porters, ticket collectors, van guards, even engine cleaners and loaders of goods trains, and, in one district in Scotland, platelayers. These women had not yet been working, he said, sufficiently long for sickness figures to be of any value, but the most outstanding thing in his experience had been the genuine enthusiasm of the women for this work, which, being mainly out of doors, was to many a welcome change from ordinary factory life, and their health did not seem to have suffered.

CHEST SURGERY IN WAR

This is one of a short series of articles based on lectures given at the British Postgraduate Medical School, Hammersmith

ABDOMINO-THORACIC INJURIES

BY

GORDON GORDON-TAYLOR, O.B.E., M.A., M.S., F.R.C.S., F.R.A.C.S.

Temporary Surgeon Rear-Admiral

Popular opinion is accustomed to associate penetrating injuries of the trunk with grievous mortality, and statistical inquiry only too truly confirms the fatality of wounds implicating the thoracic or abdominal cavity under conditions of modern warfare. The ancients knew the lethal character of wounds of this portion of the human frame; it suffices to mention here the wound of Eurymachus from the arrow from Odysseus's powerful bow, and the injuries inflicted upon Polydorus and Tros by the great Achilles or on Sarpedon by the spear of Patroklos—all these abdomino-thoracic wounds recounted in the Homeric epics proved fatal. The English stage and Scottish history also testify to the gravity of the abdomino-thoracic injury: in Shakespeare's drama, Macbeth unseamed Macdonald from "nave to chap" in the manner of one accustomed to wield the claymore. The backhand of the claymore could easily split a man from clavicle to thigh: many of General Mackay's soldiers perished in this way, endeavouring with their muskets to protect their heads and trunks in that fierce overwhelming rush of Graham of Claverhouse's men at Killiecrankie.

The surgery of those regions which adjoin the midriff is not entirely modern. The behaviour of wounds of the diaphragm received in warfare has been known to surgeons since the days of Ambroise Paré, and was accurately noted and discussed by Guthrie when writing of the war surgery of the Napoleonic era. The surgical treatment of thoracic wounds by Guthrie and by Baron Larrey, Napoleon's Surgeon General, has proved no inaccurate presage of the modern treatment of gunshot injuries of the chest. In respect of the repair of visceral injuries on the abdominal aspect of the diaphragm, over six centuries have rolled past since Henri de Mondéville counselled suture of the colon and affirmed the recovery of some of those who had received wounds of the large intestine.

Injuries which involve thorax, diaphragm, and abdomen may be of penetrating or of non-penetrating character. In the war of 1914-18 the first-named group completely overshadowed and outnumbered those which were subparietal lesions.

ON PENETRATING ABDOMINO-THORACIC INJURIES

In one series of cases from the war of 1914-18 (Sir Cuthbert Wallace, 1922) abdomino-thoracic cases constituted 12% of the abdominal cases which reached the casualty hospitals of an army; the operations performed on this group of patients also accounted for 12% of all the abdominal operations in that army. In the Spanish Civil War the proportion of abdomino-thoracic wounds in all wounds of the belly admitted to a hospital of first urgency was not dissimilar to that which obtained in 1914-18—i.e., 11% (Jolly, 1940). Abdomino-thoracic injuries formed 9% of a certain series of thoracic cases admitted to a "clearing station" (Gordon-Taylor) during 1918.

Statistics of abdomino-thoracic wounds culled from the Official History of the War of 1914-18 demonstrate that in a vast majority the abdominal lesion determines the gravity of the prognosis, and, further, that wounding of the hollow abdominal viscera greatly augments the fatality of the injury. The most fleeting glance at any anatomical atlas will demonstrate those organs most likely to suffer in abdomino-thoracic injury (Figs. 1 and 2). It will at once be apparent that the anxieties occasioned by a wound of the left dome of the diaphragm must greatly exceed those which are aroused by right-sided penetration of the midriff.

In a series of addresses on various aspects of the surgery of the chest by different lecturers it is obviously desirable to aim at some uniformity of nomenclature, classification of wounds, etc. I therefore make no apology for utilizing the excellent classification of penetrating abdomino-thoracic wounds given by my friend Tudor Edwards:

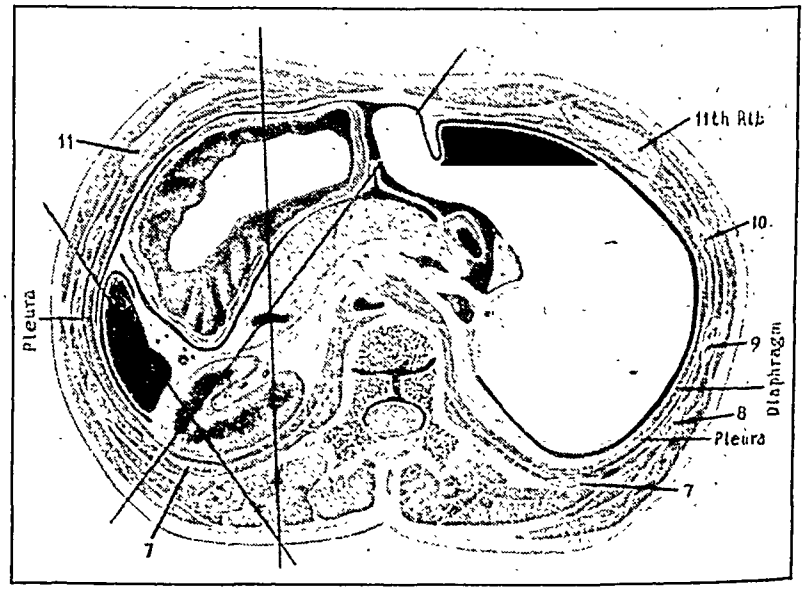

FIG. 1.—Horizontal section through abdomino-thoracic zone to demonstrate the organs liable to injury in penetrating wounds of this area.

1. The chest and abdomen may be penetrated by separate missiles, the wounded man sometimes becoming a veritable St. Sebastian, his abdomen and chest riddled with fragments of high explosive or machine-gun bullets.

2. Missiles may penetrate the chest, and may emerge through the abdominal wall or be retained within the belly; on the other hand, the track of the missile may be in the reverse direction—the wound of entry in the abdomen and the fragment retained within the thorax.

3. Traversing wounds of the lower chest, especially if inflicted during expiration, may pass through the diaphragm and occasion damage to the abdominal organs lying immediately subjacent to the midriff.

4. Tangential wounds of the lower thorax in which considerable damage, including diaphragmatic injury and perfora-

tion, is produced by the missile and in-driven fractured ribs ("stove-in chest").

The Diaphragmatic Lesion

The injuries of the diaphragm in abdomino-thoracic lesions are mostly in the sloping muscular portion, and are specially frequent where this lies in contact with the thoracic wall. In cases that come to operation the rent is usually small; in one series the linear tear was half an inch long or less in 50% of the cases. Many openings are mere punctures; larger irregular apertures in those suitable for surgery are seldom found to be more than one and a half to two inches in diameter.

Lockwood and Nixon (1918) compared the cardiac and respiratory embarrassment due to a rent in the diaphragm to that produced by an open pneumothorax; on the other hand, Sauerbruch writes that the importance of the diaphragm in relation to respiration and the circulation has been exaggerated. The great improvement in the recovery rate of abdomino-thoracic cases after the diaphragm began to be sutured by British surgeons in the last war may have been partly due to the repair of that muscle but also to the improved treatment of the thoracic condition and increasing familiarity with the many problems of war surgery. Small wounds undoubtedly heal spontaneously, and others are at least temporarily plugged by omentum, spleen, liver, stomach, etc.

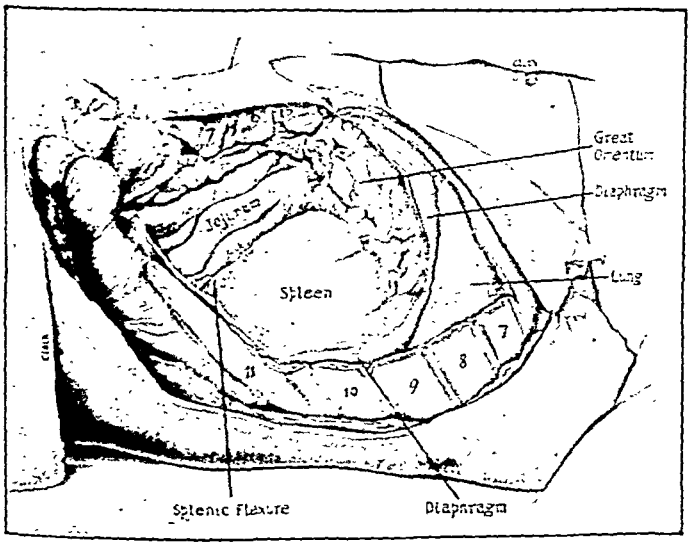

FIG. 2.—Dissection of the left-sided abdomino-thoracic region, showing viscera liable to injury in penetrating wounds. (Prepared by Prof. John Kirk, Middlesex Hospital.)

Wounds of the central tendinous part are obviously more serious than those at the periphery, but some survive. A century ago Guthrie published notes of a man with a wound of pericardium, left ventricle, lung, liver, and the tendon of the diaphragm. The man survived for four or five months; he suffered from palpitation and uneasy sensations in the chest, and died of bronchitis. Fuchsig (Sauerbruch and O'Shaughnessy, 1937) successfully operated upon a stab wound of the right ventricle which also perforated the central portion of the diaphragm. The track passed obliquely inwards from the fifth sterno-chondral articulation, and was thought before operation to implicate the stomach.

Diagnosis of Penetrating Abdomino-thoracic Wounds

Doubt may be felt at first whether the gravity of the condition of a man with an abdomino-thoracic wound is due to the thoracic, to the abdominal, or to other concomitant injury. Nixon (1919), who had great experience of these cases, writes that if there is a fair air-entry into the lungs thoracic injury is not to be held accountable.

The anatomical site of the aperture of entry and of exit of a traversing wound of the trunk limns the track of the missile with fair accuracy. The position of the patient at the time of injury also demands consideration; the structures probably damaged can then be readily adumbrated. In cases in which a fragment of metal, spicules of broken rib, etc., are retained, *radiological investigation* is indispensable; its necessity in estimating diaphragmatic movements and thoracic pathology cannot be overestimated. There are also clinical signs and symptoms which arrest attention and which may clarify, or may, on the other hand, obscure, the diagnosis.

1. *Abdominal rigidity* does not of necessity betoken involvement of the subphrenic viscera. It is well known that injuries of the pleura or lung, especially if situated in proximity to the diaphragm, may occasion abdominal rigidity and may arouse suspicion of an abdominal lesion: (*a*) The abdominal rigidity associated with an injury below the diaphragm is more likely to be bilateral; in the case of a thoracic wound rigidity of the belly wall is usually confined to one side. (*b*) The abdominal rigidity accompanying a chest injury tends to be intermittent, some relaxation of the rectus abdominis occurring during inspiration.

2. Sickness and vomiting have been known to occur in cases of lower thoracic injury, but are more frequent in abdominal lesions, as is eructation of gas.

Diaphragmatic injury is suggested by an almost entirely thoracic type of respiration, with a catch at the end of inspiration, sometimes a definite spasm or hiccup; yet the actual respiratory rate may be little altered. In the late stages of injury to the diaphragm there is fixed pain, exaggerated on exertion and referred to clavicle or scapula according to the position of the injury or location of the retained missile. Pain is induced especially by lifting, coughing, or even deep respiration. The diaphragm is kept motionless on the affected side.

The diagnosis of a wound of the diaphragm is not easy in subparietal injuries. The syndrome of tension pneumothorax may be simulated by the sudden irruption of stomach or colon into the chest. *Radiology* and the determination of the intrapleural pressure enable a correct diagnosis to be attained.

In the case of penetrating injuries the decision as to the time of operation, the type of surgical procedure, and the chronological sequence of the stages of the undertaking will depend upon: (*a*) the degree of shock and collapse of the patient; (*b*) collapse of the opposite lung, as suggested by intense dyspnoea, cyanosis, and respiratory retraction of the chest wall on the contralateral side (in such a case the administration of an anaesthetic and a thoracotomy in the last war usually proved fatal; (*c*) the experience and judgment of the surgeon.

The existence of blast-contusion of the lung is now well established on clinical and *x*-ray evidence and by post-mortem findings, yet it may be only the index of perhaps graver changes in the organs below the diaphragm. Other serious cases may have been in very close proximity to detonating bombs, and may be suffering from a dangerous and grave degree of saturation of the blood by explosive gases, such as carbon monoxide or nitric oxide. The

severity of the clinical state may even be due to such lesions as myocardial trauma. Such possibilities should not be overlooked amid the circumstances of this "total" war; their presence and the existence of other grave multiple injuries heavily load the scales against recovery.

Penetrating Injuries by Large Missiles

The injuries produced inside the abdomen by large fragments of metal or other foreign body are *almost always irrecoverable*; the result is scarcely likely to be different in those wounds if more than one cavity of the body is implicated. I have, however, figured elsewhere a piece of brass tubing, 4⅜ inches long, removed from a Greek soldier, who recovered after the simple extraction of the missile, which had passed from the middle of the right scapula and projected in the epigastrium (Gordon-Taylor, 1939).

Saint (quoted by Gordon-Taylor) had a successful right-sided abdomino-thoracic case, in which a fragment of shell weighing two ounces had traversed chest, diaphragm, and liver and produced two perforations of the duodenum and one in the hepatic flexure of the colon.

In one of my patients, the successful result of whose case is recorded elsewhere, a missile weighing nearly four ounces produced the most grievous damage inside the belly, and fractured the bony wall of the thorax (Gordon-Taylor, 1919). The diaphragm was apparently uninjured, and a strict observance of the approved nomenclature must therefore exclude this case from the category of the true "abdomino-thoracic."

(The second part of this paper will appear in next week's issue, and will contain a list of references.)

FEEDING IN WARTIME

No. 9 of the Wartime Nutrition Bulletin (May and June, 1941) summarizes the latest food facts and makes some observations and recommendations which merit attention.

Sugar and Jam

It believes, for instance, in the psychological value of the jam spread for the average child. The Ministry of Food, concerned to provide a scientifically balanced diet, may overlook these minor yet pressing questions of home life: "What can we have with our bread at tea-time to-day?" and "What is there to give the children for a treat?" The Children's Nutrition Council considers that it would have been well worth while to hold more stores of sugar in reserve. There are large West Indian surpluses available. Great Britain consumed before the war about 2½ million tons of sugar a year. Rationing has reduced this to less than 1½ million tons, of which half a million will probably come from home-grown sugar beet, leaving 1 million only to be supplied from abroad. When it is realized that 350,000 tons are available from Java and India alone, and that the Empire countries are capable of producing 1½ million tons, it will be seen that the world surplus of this commodity will be enormous.

Bread and Wheat

Wheat production is in a similar position. Most of the Australian wheat crop of 1939-40, which totalled 195 million bushels, was purchased for either export or home consumption; in fact, however, it has been possible to ship only 45 million bushels, and in December, 1940, there were 110 million bushels in hand for storage. In the last war Canada's wheat acreage was expanded from 10 to 17 million acres; in this war the position will probably be reversed. By August there is likely to be a surplus of 570 million bushels, and the total storage capacity of the country is only 470 million bushels. Storage on farms or in improvised elevators is not practicable owing to the numbers of mice and beetles that congregate in these places. Meanwhile in England we are assured that there is sufficient grain in the country and that bread is not likely to be rationed. It is not anticipated that barley or potato flour will be used, but if this should be necessary the new types of brown flour will have prepared the population for change.

The brown versus white bread controversy is still being influenced by milling and baking interests, and although the new standard loaf has become a familiar object there are areas where it is slow in making an appearance. The conflict between commercial and scientific interests is complicated by the movement away from the big mills, which are often situated in vulnerable areas, to the smaller inland mills, which are now being reconditioned. These small mills are often well fitted to produce good quality wheatmeal flour, but are at a disadvantage in manufacturing the highly processed modern white variety.

Milk

The most important factor influencing milk yield is the quantity of protein concentrates in the fodder. This is, unfortunately, higher in food coming from abroad than in home produce, so that the total milk yield is practically certain to diminish with the coming winter. It will, however, be a help if farmers can make good silage and hay from the reduced grassland now left to them. "Unprofitable" cows are being removed from the dairy herds in order to conserve food for the higher-yielding animals, but the lack of skilled farm labour may begin to have an effect upon the quality of the stock. Experience is needed in detecting abnormalities at an early stage, and if mastitis is allowed to flourish it will affect both the yield and quality of milk. It is an unfortunate result of the ploughing-up campaign that dairy farmers are obliged to spend much of their time on land cultivation. There is, too, a shortage of skilled labour in the pasteurization plants, and distribution is becoming increasingly difficult. For this reason particular care should be taken to prevent wastage through souring during the warm weather. Much of the surplus summer milk, an extra 10% beyond the normal spring flush, is being condensed, dried, or used for cheese-making. The Children's Nutrition Council considers it advisable to import during the summer as much dried milk and dried skim-milk as possible, so as to provide for the winter and early spring of next year.

Shortage of labour and difficulties of distribution are having an adverse influence on the amount of milk being made available for school children. School authorities are now acting on the recommendations of distributors that (a) the "sale or return" system is no longer justified; (b) milk should be delivered once only during the day and to one point in each school—not to several classes as formerly; (c) more care should be taken to return bottles. Board of Education Circular No. 1548, issued on April 17, admits that it will be necessary in many areas to supply milk in bulk rather than in third-pint bottles. Delivery in pint or quart bottles is, however, considered preferable to churns. Parents are asked to provide cups or beakers for the term, and the importance of cleansing these is stressed.

Vitamin C

The importance of vitamin C for children is being continually stressed. One South Midlands town is now ordering in bulk 10,000 synthetic tablets for each of ten welfare centres. If tablets are purchased in quantities of 50,000 the price is 23s. 6d. per 1,000. They are sold to mothers at a farthing per two daily doses of 12½ mg. each. It is pointed out that advertisements for products containing vitamin C are often misleading. Vitamin C may in fact be present, but in insufficient quantities.

Communal Feeding

A picture of communal feeding—the example being an East Anglian industrial town—is given by the Nutrition Bulletin. The town is an evacuation area but few people have left it. The Town Council has borne the primary cost of the five or six feeding centres which have been established, and the Ministries have now approved the scheme. The first established centre provided meals between 12 and 2 o'clock for shifts of 60 people. Numbers rose from 127 on the first day to a regular attendance of between 250 and 320. These figures were not affected by the opening of a second centre

close by, which was serving 200 people a day by the end of the first week, and many had to be turned away. Customers included a few children and an even proportion of men and women. These came mainly from factories, foundries and shops, and there were a few office workers. As a result of the success of these centres, the Feeding Committee hope to start a school feeding scheme—which this particular town has so far been lacking—if the Education Committee contributes towards the cost. Expansion of the present centres will be made to cover all school districts. The cost of meals, exclusive of overheads which cannot yet be estimated, is at present 4½d. to 4¾d. per head, the average payment being 3¾d. Children will be given a three-course meal for 4d. These low prices depend upon the purchase of bulk supplies of non-perishable foods such as dried apple rings. No tea is provided as the shift system of meals makes this difficult, but milk is sold at 2d. a cup and is popular. Local diet experts consider that the meals are well balanced, though there may be a deficiency of vitamin D.

Equipment has been expensive and there has been delay in delivery, apparently because the Ministry of Food will not help local authorities working on their own initiative so readily as they will help schemes working under their direct supervision. The limitations of the equipment and also the size of the available premises, mean that very large centres cannot be organized, and the scheme as yet covers a very small fraction of the population. But the Committee is confident that it will be possible to expand sufficiently to provide meals for all who require them, and official quarters have intimated that, if 40,000 of the population (mainly women and children) should have to be compulsorily evacuated, then the centres may be called upon to feed the workers for two meals per day. Clearly, therefore, the scheme may perform work of vital importance in maintaining health and efficiency during an emergency.

JUVENILE RHEUMATISM AND THE SIGNIFICANCE OF "GROWING PAINS"

LECTURE BY DR. JANET AITKEN

A holiday course in physical education was arranged by the Ling Physical Education Association at Bedford, when a number of lectures were delivered by various authorities, including Dr. Vaclav Benes of the Czecho-Slovak Ministry of Foreign Affairs, who spoke on education in his country, with special reference to the Sokol; Mr. Claude Bridges of the Middlesex Education Committee, who spoke on the gymnastic teacher and the law; and Miss P. C. Colson of the Government's Directorate of Physical Recreation, who described the manner in which physical recreation was being organized nationally. There were also practical classes and group discussions.

The first lecture in the course was on rheumatism in school children by Dr. JANET AITKEN, senior physician, Elizabeth Garrett Anderson Hospital, of which we give a brief summary.

The Question of Diagnosis

After referring to the very large amount of industrial incapacity resulting from diseases classed as rheumatism, and discussing the still obscure aetiology of the acute and subacute forms, Dr. Aitken took up the question of diagnosis, with special reference to "growing pains." At the beginning of the century growing pains were largely ignored by the medical profession, but during the last fifteen years perhaps an undue stress had been laid upon their importance, and in some quarters they were considered synonymous with juvenile rheumatism and the consequent danger of carditis. Limb pains in children were of two types: (1) pains which were felt in the various joints, associated in the acute phase with tenderness, swelling, and heat, and with limitation of movement in the affected part; and (2) pains which were felt in muscles or tendons, not usually tender to touch except where fibrositis was also associated. The pains in both types might be mild or severe. It was pains in the muscle which were commonly called "growing pains."

The lecturer agreed that there were numerous cases of limb pains in childhood which were not rheumatic, but she felt that the distinction was not always easy and that growing pains as opposed to arthritic pains, might be associated with juvenile rheumatism. In her series of cases, taking the rheumatic children with definite cardiac changes, the number who had muscular pains only was more than double the number who had joint pains only. It was argued sometimes that inasmuch as one-third of the children at out-patient clinics complained of growing pains, it might be expected, without associating growing pains with juvenile rheumatism, that a similar proportion of children with that complaint would also suffer from growing pains. But omitting purely joint pains which were probably included in the estimate of one-third), in her own series of cases of rheumatic carditis, at least 70% suffered from growing pains. It was also stated that young adults with mitral stenosis often affirmed that they had never had growing pains; but she had had opportunities of proving on a follow-up clinic how unreliable such histories might be.

Methodical Investigation

Dr. Aitken went on to describe in detail her method of investigation in a case of complaint of growing pains:

1. Careful consideration should be given to the possibility that some orthopaedic condition might be the cause of the pains.

2. If no cause was found and the general health was good, no treatment was necessary beyond general instructions about diet and hygiene.

3. If the general health was poor further search for the cause of the pains must be made, including the possibility of malnutrition, anaemia, and any chronic disabling disease. Should no definite cause be found the possibility of juvenile rheumatism remained, but the case should not be labelled rheumatic unless and until definite signs of that disease were present.

4. Should the growing pains persist and the health remain poor, a week or at most a fortnight in bed would very commonly result in cessation of pain and a sustained improvement in health.

5. If the pulse during sleep was raised after a week's rest and there had been even slight fever, further investigation should be undertaken. A sedimentation test was of value and an electrocardiogram might reveal some abnormality. Enlargement of the heart was, of course, of importance, but even with the help of *x* rays minor signs of enlargement were difficult to determine. Except in cases of gross cardiac disability, physical exercise was not contraindicated if under proper supervision, and massage and graduated exercise were very important during convalescence following an acute attack.

In conclusion, she said that juvenile rheumatism, though just as frequent in its occurrence, was not nearly so severe as it was ten or fifteen years ago. Gross cardiac lesions were rarely seen. This might be due to a natural cycle of severity and mildness, or, more probably, in part to an improvement in general hygiene and child welfare and in part to the greater interest taken in the prevention of disease by the medical profession and by workers in public health.

The May issue (No. 9) of *Tin and its Uses* contains a survey of the Tin Research Institute's report for 1940, describing recent technical and commercial developments in the use of tin. Important commercial applications may be found for a combined pickling and tinning process described in this issue. Another article describes the development of the Institute's chemical process for producing protective films on tinplate. The results of canning trials indicate that the film is effective in preventing sulphur staining when used for meat packs, and good results were obtained with some vegetables. *Tin and its Uses* is obtainable free of charge from the Institute, Fraser Road, Greenford, Middlesex.

Reports of Societies

TRICHINIASIS IN MAN

At a meeting of the Section of Epidemiology and State Medicine of the Royal Society of Medicine on May 23, with Dr. J. A. GLOVER in the chair, the subject of discussion was "Factors Influencing the Presence of Trichiniasis in Man."

Aetiology and Clinical Features

DR. P. B. BEESON of Harvard University said that few cases of trichiniasis had been recognized in Great Britain until recently, but the disease was fairly widespread in many temperate regions, being commonest perhaps in the United States, but very well known also in Germany and Poland. The parasite *Trichinella spiralis* had been known for over a century, and as far back as 1860 trichiniasis was shown to be responsible for severe clinical illness in man, and it was discovered that the disease was contracted by eating the pork of infested swine. Almost any animal which ate meat was liable to the disease, and it had been discovered in at least twenty-five different species. But beef, mutton, poultry, and fish did not come from animals liable to contract the disease. In the United States, where up to 5% of swine had trichiniasis, the chief factor responsible was the feeding of swine with uncooked garbage. In Britain there was little opportunity for this means of swine infestation, and the probability was that the rare cases of swine infestation which did occur in this country were acquired by eating infested rats. Trichiniasis had been found in rats in several areas.

Within the past few months several human outbreaks had been reported in different parts of England and Wales and had evoked a new interest in the clinical and epidemiological aspects of the disease. Since the beginning of this year over 200 cases of fairly severe illness due to trichiniasis had been recorded. Sausage appeared to have been the meat responsible for these local epidemics. Rationing of meat and changes in the composition of sausages had brought about a condition whereby an unusually large number of people ate the meat of a single animal. Furthermore, in view of the fact that a partially protective immunity developed after the attack of trichiniasis, the comparative susceptibility of the British population might have led to the development of more clinical cases than would have resulted from similar exposure of a population previously exposed.

Cooking was a certain means of killing any parasites which might be present in meat, but it might be inferred from the number of cases which had resulted from the eating of sausage that the temperature level necessary for the killing of the parasite was not always obtained in the frying of sausage. Ham and bacon were less dangerous because they underwent some preliminary process of salting or smoking. Refrigeration was not such a certain means of killing the parasite.

During the process of digestion the larvae were set free in the upper part of the small intestine. Here the parasite matured and copulated, the female burrowing into the bowel wall and releasing the embryos, which went into the blood stream and eventually found lodgment, perhaps in the muscles, where they might live for many years, or in the brain, heart, or lungs, where they usually excited a rather acute inflammatory reaction which succeeded in killing the parasite. The clinical syndrome had four cardinal features—fever, oedema of the orbit, eosinophilia varying from 15 to 40%, and muscle pain, often very severe, most prominent at the back of the neck, around the elbows, in the lower part of the back, and in the calves of the legs. Irritation in the lungs could produce a clinical resemblance to pneumonia. Clinical recovery usually began about the second or third week. Complete recovery was the rule. Clinical manifestations were confined to the earlier period of the infestation. Many more cases of latent trichiniasis than of the clinical disease were recognized. Two important factors influencing the clinical manifestations were the size of the infecting dose of the parasite and the resistance or susceptibility of the host. The size of the infecting dose was perhaps more important in this parasitic disease than in bacterial and virus diseases because there was no possibility of multiplication in the body of the host. Once the female had deposited its embryos no further reproduction could take place. The disease which resulted depended upon the reaction of the individual to the invasion.

In a group of six persons all of whom had had apparently the same amount of contaminated meat, four might be entirely well, one mildly ill for three or four days, and the sixth suffer from severe illness lasting for weeks. It had been shown in the case of animals that one infestation protected to a considerable extent against subsequent infestations. The clinical cases in the United States numbered about 600 in a year. In this country there had lately been three outbreaks in different towns with fifty or more cases in each, and it was likely that many hundreds of other persons were mildly ill at the same time. The only factor which seemed partly to explain why the disease should crop up at the present time was the killing of older sows for sausage meat, such sows being more likely to have been infested than the younger pigs. The most important measures of prevention were to warn the public against the dangers of eating raw or underdone pork and to intensify the campaign against rats.

Sources of Infection

PROF. R. T. LEIPER agreed with Dr. Beeson that the cause of recent outbreaks was not the rearing of pigs on swill at the same time, the widespread collection of garbage was a danger to this country. At Wolverhampton, where there had been an outbreak, an examination of 145 rats brought in by ratcatchers showed 2 to be positive. At Penrith 164 rats were examined, and 9 were found to be infested; all the infested rats had been caught at the refuse dumps, none of those caught at the sewage works were infested. He gave figures for trichiniasis in Germany in recent years. In 1922 for example, 110 cases were notified, with 1 death; in 1930 95 cases with 13 deaths; in 1934, 44 cases with 1 death. Swine infestation in the Dutch East Indies was interesting: here from 5 to 7% of female pigs were infested, and very few male pigs, but in the Dutch East Indies, although the dog was markedly susceptible, there was no recorded trichiniasis in man or in the rat. In other parts of the world the susceptibility of the cat was evidenced.

Members of Prof. Leiper's "team" and others described special investigations. Miss M. YOUNG gave an account of the examination of cysts in a number of cases coming to necropsy in the Wolverhampton district; the cause of death had been generally some cardiac condition. In 6 out of 47 such examinations it was evident that there had existed a subclinical infestation with *Trichinella spiralis*, though never diagnosed in the life of the patient. It appeared from her investigation that a certain amount of trichiniasis was endemic in the Black Country. Dr. PHYLLIS CLAPHAM mentioned some experiments which suggested that the host species played some part in determining the rate at which the female parasite matured and the embryos were liberated. Mr. J. W. G. LEIPER described clinical manifestations of trichiniasis in the pig. Dr. W. P. ROGERS illustrated the metabolism of rats with trichiniasis, a study which indicated the possibility of a biochemical diagnosis.

Dr. R. H. H. JOLLY (M.O.H., Wolverhampton) said that actually there had been 98 cases in Wolverhampton, and the epidemic covered a period of thirteen weeks. The source was traced to meat supplied very largely by three wholesale dealers. Should these outbreaks be attributed to the habits of the people or to the fact that there was a residual trichiniasis in the pig farms in that part of the country? He was of opinion that both factors came in. In 280 families in Wolverhampton, or 37% of those investigated, an admission was obtained that raw sausage was eaten, either by the housewife or by other members of the family.

FORTY YEARS OF UROLOGY

The annual meeting of the Section of Urology of the Royal Society of Medicine was addressed by Sir HUGH LETT, P.R.C.S., on his forty years' experience in that specialty. In no branch of surgery, he said, had diagnosis been brought to such a high degree of accuracy. The outstanding factors in urological progress were the discovery of *x* rays and later the development of pyelography, the remarkable evolution of the cystoscope, the tests for renal

A MAN AGED SIXTY COMPLAINED of IMPOTENCE

"... He was a thoroughly healthy man with increased subcutaneous fat on his breasts, abdomen and buttocks. ... After a preliminary course of injections ... potency was regained ... and local inunction of an ointment was started.

"Apart from the maintenance of sexual function, the most obvious effects have been the new growth of hair and an increase in virility enabling this patient of 60 to play 36 holes of golf without undue fatigue."

MEDICAL PRACTICE

REQUIRES THE SUPPORT OF THE BEST AND MOST RELIABLE DRUGS

MAY & BAKER offer for the choice of the medical practitioner a wide range of British preparations of established repute. Wherever his practice, he will daily have occasion to prescribe one or other of these drugs.

★ **DAGENAN—M & B 693** ★
For pneumococcal, gonococcal and meningococcal infections.

★ **SOLUSEPTASINE**
For parenteral administration in streptococcal infections.

★ **MYOCRISIN**
For the gold therapy of rheumatoid arthritis.

★ **GARDENAL**
For epilepsy.

★ **RUTONAL**
For epilepsy.

★ **PROSEPTASINE**
For oral administration in streptococcal infections.

★ **SONERYL**
For insomnia.

★ **SONALGIN**
For insomnia associated with pain.

★ **S.V.C.**
For trichomonal vaginitis.

★ **CYCLONAL SODIUM**
For intravenous anæsthesia.

FORTY YEARS OF UROLOGY

efficiency, and the advances in the medical treatment of urinary infections. In its early days pyelography was not devoid of risk, for collargol was employed as the opaque medium, and unfortunately it led to a fatal issue in certain cases in which the pelvis was overdistended, and as a result the calices ruptured and pyelo-venous backflow ensued. This difficulty was overcome by substituting for collargol a solution of sodium bromide or iodide, which was innocuous and proved satisfactory. But although ascending pyelography was of value in the diagnosis of obscure cases, it was not always applicable, necessitating as it did the passage of a catheter up the ureter to the renal pelvis. The discovery of intravenous pyelography was a great advance, and now the urinary surgeon would regard an operation on the kidney as unthinkable unless either intravenous or catheter pyelograms, or both, had previously been made.

Treatment of Prostatic Obstruction

The developments in the treatment of prostatic obstruction made one of the most interesting chapters in the progress of urinary surgery. For many years catheterization had been the routine. Catheter life, as it was called, was strongly condemned, and it had even been stated that patients who wholly depended on the catheter were not likely to survive for more than two years. This was not so provided that adequate precautions were taken and the patients kept under careful supervision. Sir Buckston Browne had two patients who lived to be a hundred, and for the last twenty years of their lives passed all their urine by catheter But there were cases in which catheter life was unsuitable or even impossible

Suprapubic prostatectomy was first performed by Belfield in the United States and McGill in this country In 1901 Freyer started his campaign, and by persistent advocacy made suprapubic prostatectomy the standard surgical treatment of enlarged prostate. The general mortality, however, was heavy, some patients dying from haemorrhage and some from infection, but most often the deaths were from uraemia Not until 1909 was attention drawn by Stillman to the value of preliminary decompression in these cases, either by catheter or through a suprapubic puncture but some years elapsed before its importance was generally realized The adoption of decompression in certain cases and the discovery of the tests for renal efficiency, particularly those for estimating the retention and excretion of nitrogen, stood out as landmarks in the history of prostatectomy. Any discussion on prostatectomy would be incomplete without a reference to resection by diathermy. In skilled hands this had proved particularly useful when the prostate was small or when the obstruction was caused by a middle lobe But, in this country at least suprapubic prostatectomy remained the operation of choice when the gland was much enlarged

One of the greatest triumphs in the history of bladder surgery was the destruction of vesical papillomata by diathermy, introduced by Beer in 1910. How great it was could only be realized by those who saw these cases when the only method of treating recurrences was by further operations, whereas now all that was needed was a simple treatment which could be given in the consulting-room or the out-patient department.

The Urethra and Urethroscopy

One of the considerable changes which had taken place in hospital practice during the last forty years was the decline in the number of patients who presented themselves with strictures of the urethra which were severe and almost impermeable or associated with important complications. At the London Hospital in 1897 no fewer than 50 cases of stricture were operated on, 45 by internal and 5 by external urethrotomy, but in 1937 there were only 4, all treated by internal urethrotomy. Again, in 1897 there were 19 cases of perineal abscess and 6 of extravasation, and in 1937 only a solitary case of perineal abscess. In addition, 27 cases were treated by dilatation under an anaesthetic in 1897 and 16 in 1937. These were remarkable figures. The great majority of strictures were due to gonorrhoea, the treatment of which forty years ago was limited almost entirely to drugs and local injections of astringent or antiseptic lotions by a hand syringe. It was not surprising that many patients were uncured, and only those who saw those cases and knew how difficult they were could fully sympathize with Ricord's remark, picturing hell as a place where he was surrounded by patients suffering from uncured gleet! Only when the urethroscope was modified to allow air distension did it become of real value. Then it became possible to diagnose and treat with far greater accuracy local lesions and also to discover areas of local infiltration which limited the expansion of the urethra under air distension and treat them by full dilatation with a Kollmann dilator. The value of the urethroscope in this respect was summed up by Frank Kidd, who said that with this instrument the course of a stricture could be followed from its birth until, at the hands of the Kollmann dilator, it met its death

Sir Hugh Lett concluded with some remarks on the difference between forty years ago and to-day in respect of antiseptic precautions The scanty regard paid to surgical cleanliness in those early days offered a ready explanation of the cases of perineal abscess and extravasation of urine and cellulitis that so often occurred. To-day adequate precautions were taken against infection, the urethra was carefully irrigated, and every instrument introduced into it was sterilized Instances of urinary fever were very rare in relation to the large number of cases now treated in urological clinics and out-patient departments, and the fact that so much instrumentation could be done without ill effects was a striking testimony to the progress made during the last forty years. He paid tribute to the work of British urologists—Thomson Walker, Frank Kidd, and Hurry Fenwick (the "wizard of the cystoscope"), among others.

Mr JOCELYN SWAN added a few remarks in the same vein of reminiscence Progress in urology, he said, had been due to three factors: cystoscopy, x rays, and chemistry. There had never been sufficient collaboration between the surgeon and the radiologist. Intravenous pyelography should not be entirely relied upon, because very often there was a rather doubtful shadow; it should be followed by an ascending pyelogram before the condition was determined In urological conditions, especially growths in the testes, but also in the bladder, x rays were of value in treatment as well as in diagnosis Contact therapy by the Chaoul apparatus had proved of service He uttered a word of warning against indiscriminate chemotherapy. He had seen two patients die after comparatively small doses of sulphapyridine, and he had seen other unfortunate, though not fatal, results. All cases which were given any of the sulphonamide drugs should have a forced fluid intake, and careful quantitative estimation should be made

FATIGUE AFTER SKILLED WORK

The Ferrier Lecture on "Fatigue following Highly Skilled Work" was delivered before the Royal Society by Prof. F. C. BARTLETT, F.R.S., on May 29.

If the character and causation of fatigue following highly skilled work were to be understood, the first need, he said, was for the discovery of more relevant and experimentally controlled facts. Unfortunately almost all the investigators who had attempted to study fatigue of this type had adopted methods taken over with very slight change from those which had proved valuable in the study of simple muscular fatigue. They chose elementary operations usually considered to require some "mental" effort—such as easy calculations, word or colour recogniton, and naming and the like—repeated these operations over and over again for long periods, and tried to express the resulting fatigue in terms of the diminution in quantity or quality of the work done. The skill fatigue of daily life was not set up under such conditions. Routine repetition of simple actions was not a characteristic of any highly skilled work, and least of all of work having a strong "mental" component. The operations involved here were marked by complex, co-ordinated, and accurately *timed* activities. The stimuli in response to which these activities were set up were neither simple nor did they usually fall into an order of fixed succession. They had the character of a field, or a pattern, which had become very highly organized, and might retain its identity in spite of a great diversity of internal arrangement.

It was possible to develop fully controlled experimental situations in which these realistic considerations had full play. When this was done the picture of fatigue following highly skilled work which emerged had certain strongly marked characters. In such fatigue the "standards" accepted and followed by the central nervous system unwittingly deteriorated. The operator tended to think that he was doing better work, because errors treated as significant all the time got wider and wider limits. Until a stage of great fatigue was reached it was far more likely that the actions would be performed at the wrong times than that the wrong actions would be performed. If accurate timing was insisted upon, gross mistakes of action might appear. The stimulus field split up. Its pattern character altered. It became a collection of unconnected signals for action, with some of these predominant over all the others. Particularly stimuli which were in the margin of the pattern, not closely

organized with the central field, were ignored, "forgotten," and serious lapses of specific reactions occurred. There was a marked change in the effect of certain "distracting" or additional stimuli. Sensations of bodily origin, in particular, became more pressing and insistent and affected the performance in ways peculiar to the tired operator. Side by side with all these changes went constant subjective symptoms. Verbal reports about any circumstances connected with known failure of performance became increasingly inaccurate, and errors were regularly projected upon objective conditions, or attributed to the interference of other people. There was a tremendous growth of irritability.

In conclusion, Prof. Bartlett discussed the light thrown by this picture upon the relation of high-level central nervous functions to simpler neuromuscular mechanisms.

Correspondence

The Chronic Sick in Bombed Towns

SIR,—I am informed from absolutely reliable sources that there are still hundreds, if not indeed thousands, of "chronic sick patients" being maintained in institutions in those of our large towns which have been repeatedly bombed during the last few months. I am also informed that, despite the facts that many "chronic sick" patients have been killed and others seriously injured, and that in some instances the buildings in which they are housed have been seriously damaged with consequent great discomfort to both patients and staff, the Ministry of Health obstinately declines to remove these unfortunate bedridden patients to places of comparative safety and comfort outside our large towns.

If Hitler was our Minister of Health it would be easy to understand, but what are we to say when this sort of thing goes on unheeded in our own Christian country and yet no one makes any attempt to raise the question either in the Press or in Parliament? I may add that I have written to one of our prominent daily papers on the subject: they have simply refused to publish my letter. Why has it escaped the notice of our medical Members of Parliament, or are they afraid to raise such a ghastly injustice in the House? I am writing this letter to you, Mr. Editor, in the hope that the *British Medical Journal* will vigorously advocate immediate steps being taken to put an end to the agonizing apprehension from which these poor persons must be suffering from day to day and night to night.

Perhaps it might be worth while adding that the accuracy of the statements made to me can easily be tested by a question in the House as to the numbers of such persons still being housed in public health and public assistance institutions as well as voluntary hospitals and homes for incurables in London and other large towns.—I am, etc.,

Criccieth, May 22. FREDERICK MENZIES.

Control of Tuberculosis

SIR,—In these days of strain and hustle of war, tuberculosis is apt to be forgotten or shelved. Dr. James Maxwell's article (May 3, p. 665) on the dangers from the tubercle carrier is a timely reminder and warning, and should indicate that there are defects—serious defects—in our tuberculosis service. Are we on right lines? The facts outlined by Dr. Maxwell would seem to show that we are not. Year by year we spend large sums on sanatorium treatment—treatment which is costly and disappointing when compared with other standards in medicine. We patch up lungs and perhaps add a year or two to the life of the consumptive, but massive infection and bad home conditions still hold sway and account for thousands of cases of tuberculosis every year. The death rate has fallen certainly, but tuberculosis still attacks the person we can least afford to lose—the young adult. Yet we allow the open case or carrier to leave sanatorium, with or without consent, to return home to infect others. In time these contacts themselves become tuberculous and find their way to our orthopaedic hospitals and sanatoria; and so the vicious cycle is complete.

Our costs are increasing, taxation (local and national) is increasing, and our post-war commitments are likely to be on a colossal scale. Let us therefore direct expenditure on tuberculosis into channels most likely to produce results. Prevention is still the keynote to success. After twenty years' experience in tuberculosis I would suggest the following:

(a) Select a number of sanatoria up and down the country where up-to-date treatment and diagnosis can be carried out and pool the beds. Divide the country into regions and then invite local authorities to join together to share these beds. This would allow the smaller and poorer authorities to get over the difficulty of providing costly sanatoria of their own. If fresh air and rest is all that is required, this could be carried out at home under the supervision of the medical attendant. Confine admissions only to such cases as will respond to skilled treatment—that is, to some form of collapse therapy. Stop crowding our sanatoria with chronics and incurables.

(b) Adequate accommodation for the segregation of open and advanced cases. It should be incumbent upon every scheme-making authority to provide this in institutions near the homes of the patients and in the substandard sanatoria. Regard tuberculosis as an infectious disease and make the segregation of open cases or carriers compulsory until such time as they can be rendered safe. The present law requires amending to simplify its application.

(c) Compel local authorities to provide adequate housing accommodation for its tuberculous population—subsidizing the houses if need be.

(d) Introduce a pension scheme for tuberculosis. It is well known that poverty and privation lead to a furtherance of the disease in families. Link this scheme up with an extension of the training college and settlement scheme on Papworth principles, with at least one colony for each region.

(e) A stricter control of the milk supply.

It may be said that to carry out these proposals will add considerably to the cost of tuberculosis. The initial cost may be great, but I believe it would be money well spent and in time would reap its own reward and effect a considerable saving to the nation. I may add that these are entirely my own personal views.—I am, etc.,

Wakefield, May 14. G. E. JOHNSTON.

"Bureaucratic Surgery"

SIR,—The correspondence under this caption initiated by Mr. Norman C. Lake (April 19, p. 602) must be welcomed by all who are interested in the welfare of the E.M.S.

The improvisations of September, 1939, are evolving into a more organized service, and only those responsible for its efficiency can be fully aware of its many difficulties. These are inherent in the grouping together of varied medical services and their change over from a peacetime to a wartime basis. It is no doubt in these circumstances that "the latest orders" of which Mr. Lake complains have arisen—namely, that all head injuries should be transferred for treatment to special neurological units, the term "head injury" to include scalp wounds in which there is no evidence of bone involvement. In support of this instruction Mr. D. W. C. Northfield (May 10, p. 728) cites certain cases of bad surgery which have come to his notice as surgeon in charge of a special head centre. But, surely, ignorant surgery is not to be bettered by withdrawing all cases into special centres, but by spreading more knowledge to engender better surgery.

Without doubt, wherever it is possible to develop a highly organized service, then special centres are of the greatest value and surely welcomed by all. But, again, will either the public or even special centres be well served if it is they who are "to tackle everything"? There is surely a surgery, informed and restrained, which is immediate to the wounding, and which extends to the first hospital of reception. Few will suggest that an open extradural or sinus haemorrhage should be left to be transferred to a special centre, and, further, there is a surgery of knowledge, rather than immediate action, in the constant watch for neurological signs in the unconscious patient too ill to be moved. Again, cases of multiple wounding (and there are many of them)—say a scalp wound and a penetrating abdominal wound—immediately dispose of bureaucratic surgery and require investigation, judgment, and prompt treatment. Selection of suitable cases for transfer to special centres must vary somewhat with time and place, but with co-operation is not difficult. Selection is based on knowledge and not dangerous rule of thumb.

To the special centres the general surgeons should look for knowledge, research, instruction, and an understanding of both their difficulties and their opportunities. Good general surgeons will certainly not be made by depriving them of all their material—the *reductio ad absurdum* of the extreme specialization to which Mr. Lake refers.

The hard anvil of war has exposed many weaknesses, not the least of which, perhaps, is the unfortunate specialist who finds himself promoted "general surgeon," with many responsibilities for which he has had neither the training nor the experience. Amid the uncertainties of total war, the most generally useful tool will be the man who is well trained in the traumatology of all the systems, and his loss will be greater than any other. However, the general surgeon and the specialist are not mutually exclusive but complementary. The danger lies in promoting one at the expense of the other. Perhaps the best work of special centres will be in the training of more and better general war surgeons.

The Postgraduate School at Hammersmith has provided some excellent lectures on war surgery. Its work should be extended both in London and in the country, and its value would be greatly enhanced on the clinical side by the co-operation of the special centres. We badly need a school of military or war surgery for all who would aspire to the honour of treating the wounded.—I am, etc.,

J. M. CHRISTIE, M.B., F.R.C.S.Ed.

London, N.8, May 17.

Pulmonary Concussion

SIR,—The advantage of using the term "pulmonary concussion" for haemorrhagic lung lesions due to trauma is that it does not limit us by views on aetiology not generally agreed upon. This admission that I did not know what part blast played in causing the lesions reported (April 5, p. 506) makes the letters of Prof. S. Zuckerman and Dr. P. L. Krohn (April 26, p. 645) largely meaningless. It was shown that pulmonary concussion occurs more frequently in the victims from bombed houses—that does suggest that blast has been a factor. Necropsies on air-raid victims should be on unselected cases, as with road accidents the probability of lung lesions depends largely on the type of victim but cannot be foretold.

I hope that Prof. Zuckerman will not continue to detract from his valuable experimental work by making statements about humans which are almost nonsense—for example (1) To speak entirely in terms of wave motion in bombed houses, etc., is misleading; there has been a sudden addition of a large volume of gas which must escape. In many houses the thin dividing walls offer least resistance and probably go first. Such houses may go as a unit; I am sure I have seen some which did. The familiar mess makes the statement by Prof. Zuckerman comic relief (unless it refers to animal experiments). "If the explosion is insufficient to break the walls of an 'average' house (that is, if the explosion is a small one) the blast wave is reflected from wall to wall until its energy is absorbed and the pressure falls to that of the normal atmosphere." (2) The human factor is so variable that it would be surprising if the same lesions were found in different people after exposure to the same force (except that be, as Dr. Krohn reminds me within 10 feet of a 500 lb. bomb). Will an accurate history of the incident ever tell us if the lungs were in the inspiratory position at the time of the explosion? In bombed houses (with explosions) there will always be many unknowns. Prof. Zuckerman should realize, the extent to which he has forgotten the human factor from a fantastic comment he made on his Case 2 (*Proc. roy. Soc. Med.*, 1941, 34, 185). Case 2 was a woman in a steel shelter with three other people. A near miss displaced the shelter 30 feet. The only fatality was this woman, who sustained lung lesions. "After speculating on the cause of these lung lesions he says, "On the other hand, the possibility that she may have been directly affected by blast cannot be excluded, for it is conceivable that she was just within, and the other occupants of the shelter just outside, the cone of blast." (3) This idea of a force threshold cannot be accepted for human beings; it is how the force is applied that matters. If there is a force threshold, then the two strong men who died after simple falls (*Journal*, 1940, 2, 317) should not have done so, and a young sailor who was run over by a trailer weighing 5 tons 15 cwt. should have had pulmonary concussion but did not (case reported in *British Heart Journal* by Dr. Hugh Barber and myself).

Dr. Krohn makes the old mistake of thinking that animal results will be reproduced in detail by human beings when he speaks of the abdominal lesions. The compressive force sends the base of the lungs, etc., downwards and the abdominal organs upwards; they meet going in opposite directions; hence the lesions are typically of upper abdominal organs. Mere crushing is not the whole answer.

Many misunderstandings would be avoided if the pathology of the lesions were agreed upon. I suggest that "pulmonary concussion" be used in a broad sense for haemorrhagic lung lesions due to trauma. When, and if, a lesion caused by blast alone is proved "blast" should be in its name. Pulmonary concussion has primary, secondary, and reactionary lesions. The primary lesions are (1) phrenico-costal sinus contusion, (2) "rib markings," and (3) massive hilar contusions. These need not all be present and in severe cases may be confluent. The first two types are common in civil life, the third is rare—I believe it is brought about by a mechanism similar to the penny experiment (Sutherland, G. A., *Lancet*, 1940, 2, 641). Each alveolus with air locked in by glottic spasm and speed of compression acts as a penny and transmits the force until the immovable structures near the hilus are reached; here the alveoli are ruptured. I believe that it takes a very large force to cause massive hilar contusion and that this is the lesion Dr. Joan M. Ross (*Journal*, January 18, p. 79) speaks of as essentially a lesion of blast. The secondary lesion is multiple spots of inhaled blood; this may be so mixed with the primary lesions that it will be difficult to unravel them. Reactionary lesions still need much observation.

Further observations are much needed on:

(1) The reaction of the lung to inhaled blood. Ideal subjects for this study are suicides who shoot themselves through the head. The amount of congestion and fluid effusion into alveoli about some of these haemorrhagic spots is surprising—unlike the big primary lesions where the capillaries are compressed by the blood. This secondary lesion has been confused with the primary concussive ones in some cases which have been reported.

(2) The process by which the large lesions resolve—may cavitation follow pressure necrosis of alveolar walls?

(3) The incidence of lung lesions in minor cases.

(4) More radiological surveys similar to that of Dr. J. L. Livingstone (*Proc. roy. Soc. Med.*, 1940, 34, 90), where lesions are correlated with the "state of the patient."

Dr. Krohn shows that he does not understand the clinical problem when he says that pulmonary concussion is infrequent in hospital practice because Dr. A. M. M. Payne (*Journal*, April 12, p. 564) found no case in 226 admissions. Dr. Payne writes "from the point of view of the organizer," not the research worker. Pulmonary concussion is often a sub-clinical entity; it can frequently be overlooked with no danger to the patient; for example, a woman had a bomb injury of the brain which proved fatal after two and a half months; at necropsy I found a right phrenico-costal sinus contusion which had not been recognized and played no part in causing her death. These lung lesions are common in the wards just as they are in the post-mortem room, but they have to be hunted for in unselected cases. The subject is a research one to a very large extent, and for that reason I should like to see groups of pathologists, radiologists, and clinicians appointed to see the lungs of as many air-raid victims as possible.—I am, etc.,

G. R. OSBORN.

Derby, May 17.

Silk in the Darning of Hernias

SIR,—If Mr. Rodney Maingot, who writes on this subject in your issue for May 24 (p. 777), will refer to the *Journal* of November 25, 1922 (p. 1024), he will find a full description of the method, which I had then used for many years. It is, however, notorious that the employment of plain silk introduces a certain risk of infection even in the most careful hands, and I therefore used a method of preparation developed from that devised by Lange some thirty-five years ago. Briefly, floss silk is boiled for one hour in 1/1,000 biniodide of mercury in watery solution, transferred from this to 1/1,000 biniodide in alcohol for dehydration, and kept for storage in liquid parolein. The silk thus treated is soft and flexible, retains its full tensile

strength, and sets up no irritation in the tissues. The impregnation with a mercury salt renders it immune to early infection but does not prevent the ingrowth of tissue cells, which ultimately convert it into an inextensible structure closely resembling tendon in its histology. Lange used mercurialized silk for the construction of artificial tendons with great success, and I have myself employed it for this purpose on many occasions. It furnishes a surgical material of first-rate value and many applications, among which the treatment of difficult hernias is not the least important.—I am, etc.,

London, May 26. H. S. SOUTTAR.

Subcutaneous Ligature of Veins

SIR,—Critics of my method of subcutaneous ligature (April 26, p. 626) suggest that it is painful, dangerous, and unreliable. With your permission I shall try to correct these impressions.

Essentially, the method entails inserting one stitch in clean skin. Most doctors would agree that they can do this safely, and in fact do so on many occasions in their ordinary work. Mr. N. L. Eckhoff (May 10, p. 729) quotes cases of recurrence after saphenous ligation, but does not allow for the effect of the sclerosing injections. Combining injections and ligation enables the whole length of the affected vein to be completely blocked. Early recurrence in these circumstances appears most unlikely if venous pressure at the upper limit of the occluded portion is normal. This latter proviso must apply to any method of treatment. I agree with Mr. Eckhoff that the Trendelenburg operation is a serious business, with possibilities of disaster, and would suggest that it be reserved for the worst cases.

Dr. S. McAusland (May 17, p. 763) describes the method as "crude," and states, wrongly, that the needle is passed through the vein. The small Rotunda pattern needle is passed between the vein and the deep fascia, and with practice perforation of the vein does not occur. Using novocain as described, there is no more pain caused than an ordinary injection of sodium morrhuate would be expected to produce. "Crude" is the last word one would apply to any method which obtains the desired result with the maximum economy of effort.

My excuse for writing to you at this length is simply this. Dr. Sicard described his method of treating varix by injection in 1923. In spite of the efforts of surgeons and general practitioners, there are still thousands of people in need of effective treatment. In my own practice in two years I have found nearly forty cases requiring ligature. One can only guess at the total number in the country, but it is apparent that all the theatre staffs available could make very little impression on it.

I would urge, therefore, that general practitioners should grapple with the problem, using the method they find best, and make a determined effort to abolish varicose veins.—I am, etc.,

Bradford, May 19. H. S. RUSSELL.

Adrenal Grafts in Addison's Disease

SIR,—In their article on the treatment of Addison's disease by adrenal graft (April 26, p. 617) Drs. F. Katz and F. Mainzer say that a transplantation should not be looked upon as successful "unless there is definite improvement over a period of months in a case of undoubted Addison's disease." They could find only five cases in the literature which fulfilled these requirements, the periods of observation varying between five and twelve months. Their own case was observed for fifteen months after the operation, but, as Dr. J. J. Conybeare rightly pointed out (May 3, p. 688), the diagnosis could not be regarded as indisputable, as there was never any pigmentation of the skin or mucous membrane.

The following case shows that even an extreme degree of pigmentation of skin and mucous membrane does not make the diagnosis certain, nor does improvement lasting for two years prove that an adrenal graft has effected a cure of the disease. A man of 41 was admitted under my care at Guy's in November, 1920, for increasing asthenia with occasional vomiting since January. During this period his skin had become deeply pigmented, and there were numerous dark patches and black spots in addition to the general brown colour. Patches of brown pigmentation were present in the mucous membrane of his mouth. On admission his systolic blood pressure was 120 mm. Hg, but it fell to 80 mm. during his stay in hospital. He was readmitted in April, 1921; he was so weak that he could neither walk nor stand. Mr. W. E. Tanner then grafted into the patient's testicle the adrenal gland of an eight-months infant immediately after its death, which occurred during parturition. The patient's blood pressure rose in the next four weeks from 75 mm. to 120 mm., the vomiting ceased, and he regained his strength sufficiently to be able to do light work, but the pigmentation remained unaltered. He was shown at a meeting of the Clinical Section of the Royal Society of Medicine in February, 1922, when he was accepted as a typical case of Addison's disease apparently cured by an adrenal graft.

He remained at work for another year. His symptoms then gradually returned, and he was found to have anaemia with a high colour index, achlorhydria, and a slightly enlarged and hard spleen and liver. It was now thought that he might have Addison's (pernicious) anaemia simultaneously with Addison's disease. On June 12, 1923, his condition suddenly deteriorated, his blood pressure fell to 90 mm., and he died in July—two years and three months after the operation and three years and eight months after the onset of symptoms.

At the post-mortem the adrenal glands were found on macroscopic and microscopical examination to be perfectly healthy. His liver was cirrhotic and contained excess of iron. There can be little doubt that he died from Addison's anaemia and that this was the cause of his pigmentation. Some excess of fibrous tissue, but no trace of adrenal tissue, was discovered on microscopical examination of his testicle.

I may add that among the numerous physicians who saw the patient during the two years he was under observation, the only one who even questioned the diagnosis of Addison's disease was Dr. J. J. Conybeare.—I am, etc.

Oxford, May 21. ARTHUR HURST.

SIR,—With reference to the paper by Drs. F. Katz and F. Mainzer (April 26, p. 617) and subsequent correspondence, may I state that, although it is obviously prudent to question the diagnosis in a case of supposed Addison's disease without pigmentation, such an apparent absence of pigmentation does not signify the incorrectness of the diagnosis. Obvious pigmentation of the buccal mucous membrane is not an essential feature of Addison's disease, and pigmentation of the skin may be inconspicuous in acute cases or in fair-skinned patients. Nevertheless, a case of supposed Addison's disease without pigmentation and without the characteristic biochemical changes in sodium metabolism is not an ideal one to illustrate the apparent benefit from an adrenal graft. In my limited experience of the effect of adrenal grafts in Addison's disease the result is either negative or temporary, but others may well have been more fortunate.

The implantation of tablets of desoxycorticosterone in the subcutaneous tissue under local anaesthesia is a procedure which is effective for a period of some four or more months and can be repeated. In this connexion one must remember that desoxycorticosterone is not the only essential hormone of the adrenal gland, but the clinical effect is usually satisfactory.

Although Dr. H. M. Stanley Turner (May 24, p. 798) gives theoretical reasons for suggesting that the prognosis in women with Addison's disease would be less unfavourable than in men, in actual fact this does not appear to be the case, although occasionally one meets with a woman patient who seems to make a recovery following the climacteric, the assumption here being that the adrenal cortex, as well as the pituitary, undergoes hypertrophy in this phase.—I am, etc.,

London, W.1, May 23. S. L. SIMPSON, M.D., F.R.C.P.

Acute Abdominal Pain after Opium

SIR,—The experiences which have been recorded under the above heading are probably explained by the experiments carried on for several years at the Mayo Clinic on the mode of production of biliary colic, especially by W. L. Butsch, J. M. McGowan, and W. Walters (*Surg. Gynec. Obstet.*, 1936, 63, 451). These experiments have received less attention than they deserve. When a meal is taken the gall-bladder contracts, the sphincter of Oddi relaxes, and the bile runs into the duodenum. The pressure necessary to overcome the

resistance of the sphincter is usually low—about 20 mm. of water. It was found that in normal animals morphine causes contraction of the sphincter. A subcutaneous injection of 1/6 grain of morphine sulphate caused the pressure in the common bile duct in man to rise to 200 to 300 mm., the rise starting in a few minutes and lasting several hours. In those patients who had previously had colic a similar pain occurred, but in others only discomfort; yet it would not be surprising if more severe symptoms were met with in an occasional case. These experiments explain the common clinical observation that biliary colic is often made worse by a small injection of morphine, the drug being ineffective until the dose is so large that its dulling action on the higher centres overrides the increased spasms of the sphincter of Oddi and the rise of intrabiliary pressure which is the origin of the pain. Atropine causes relaxation of the sphincter normally, but has little or no effect in counteracting the action of morphine. Inhalation of amyl nitrite may produce an instant fall of pressure and relief of symptoms, but the action is temporary. Glyceryl trinitrate grain 1/100 placed under the tongue has a similar action—slower in onset but more lasting. These results have been confirmed by H. Doubilet and R. Colt of New York (*Surg. Gynec. Obstet.*, 1937, 64, 622).—I am, etc.,

London, W.1, May 25. H. LETHEBY TIDY.

Capillary Fragility and Vitamin C

SIR,—The conclusion of Drs. N. U. Khan and M. Minn (May 17, p. 752) that capillary resistance decreases as diet deteriorates is hardly justified on a basis of forty children (even were it shown that the eight children with high petechial counts had persistently high counts before ascorbic acid was given to them). Although some authors consider capillary resistance a dependable test of vitamin C intake, others disagree. Greene (*J. Amer. med. Ass.*, 1934, 103, 4) found that lowered capillary resistance did not necessarily denote low vitamin C intake in children. He found much variation in capillary resistance when the same children were tested at different times. Rapaport *et al.* (*J. Pediat.*, 1940, 16, 624) titrated the vitamin C in the blood plasma of children. They found no correlation between low capillary resistance and hypovitaminosis C.

Positive-pressure capillary resistance tests should be done simultaneously on both arms, as the difference between the number of petechiae on each arm may be large. Subjects with low capillary resistance should be tested repeatedly, and it should be noted that healthy persons on the same diet may show marked differences in capillary resistance (for example, Davis, *Lancet*, 1940, 2, 312).—I am, etc.,

London, S.E.10, May 21. ELI DAVIS.

Laryngitis in Secondary Syphilis

SIR,—In your issue for May 24 (p. 798) there is a letter from Major H. S. Sharp describing a case of "secondary syphilis is one of its rarer manifestations—that is, laryngitis." According to this letter, the "points of interest are: (1) The only complaint was hoarseness; the appearance of the larynx suggested the diagnosis. (2) Mucous patches on the tongue only."

The laryngitis described in this case is most certainly not a rare, but an exceedingly common, manifestation of the secondary phase of syphilis. In my book *Venereal Diseases* (p. 147) is set out a table showing that in a series of 500 consecutive patients of both sexes sore throat and hoarseness occurred in 54 per cent. Where the vocal cords show only hyperaemia and no mucous patches or eroded areas the condition is usually quite painless. The peculiar type of hoarseness is practically pathognomonic. The presence of mucous patches upon the tongue only is not in the least degree uncommon in secondary syphilis. Before the patient reported sick, however, such patches may have been present on other parts of the buccal mucous membrane. Such lesions are often very evanescent—here to-day and gone to-morrow.

From the description of the voice, the larynx, the tongue lesions, and the cervical adenitis, the diagnosis of syphilis was much more than merely suggested, and hardly required—except in the interests of completeness—the discovery of anal condylomata lata, a positive blood serology, and a history of a penile sore.

When I was director of the L.C.C. (Whitechapel) Clinic and lecturer in V.D. at the London Hospital Medical College, I would have been very disappointed in any medical student or postgraduate who regarded the conditions set forth in Major Sharp's letter as being rarities in the acute (secondary) stage of syphilis.—I am, etc.,

Paignton, Devon, May 24. E. T. BURKE.

Loss of Vision following Haemorrhage

SIR,—In his article on loss of vision following haemorrhage (May 24, p. 774) Colonel H. L. Tidy states that only one case of severe loss of vision occurring in pernicious anaemia has been recorded in the literature. This statement appears to be at variance with recent reports of optic atrophy occurring in this disease.

Prof. Henry Cohen has reported cases in which the earliest clinical feature of this disorder was optic atrophy (*Lancet*, 1936, 2, 1202). Similar cases demonstrating the association of pernicious anaemia with optic atrophy have been recorded by Kampmeier and Jones (*Amer. J. med. Sci.*, 1938, 195, 633), and Aldren Turner (*Brain*, 1940, 63, 225). That the visual loss in such cases is not directly attributable to the anaemic state of the blood is shown by its occurrence when the blood count and haemoglobin content are but little altered.—I am, etc.,

London, S.W.6, May 29. L. HARRIS, M.B.

Scabies Epidemic in a Civil Population

SIR,—In the last months of the year 1918 there was an outbreak of scabies in Vienna which spread rapidly. The Ministry for Public Health therefore decided, on the advice of M. Oppenheim, to open a special centre for the treatment of scabies, which was attached to the Department for Skin Diseases of the Wilhelminen-Hospital. The expenses were paid partly by the Government and partly by the panel for workmen. While in the time from 1918 to 1929 27,413 patients were treated, their number fell steadily in proportion to the improvement of the social conditions, especially of the housing accommodation. In 1925 there were 1,031 and in 1930 only 276 patients. After 1931 there followed a sharp rise, and in 1935 (last available figure) 2,539 patients had to be treated. There can be no doubt that that increase was caused by the economic crisis prevailing at that time in Central Europe.

The treatment carried out at the centre was as follows. After the patient had been rubbed with soft soap he got a bath for about half an hour. After the bath the body was dried and rubbed with Hardy's ointment (pot. carbonate 1 drachm, sublimed sulphur 2 drachms, petroleum jelly 1½ oz.). The patient was covered with blankets and had to stay for two hours in a warm room. The treatment ended with a bath and the application of Lassar's zinc paste. The whole treatment lasted for about four hours, and therefore it was possible to work in two or even in three shifts a day.

The excellent results obtained with the work of the centre seemed to depend on several factors: Diagnosis and treatment were concentrated at one place, where a trained staff was available. It might be pointed out that the diagnosis of scabies can be very difficult sometimes—for example, early scabies of people who live hygienically, cases masked by a dermatitis or an eczema following improper treatment, and, especially among children, cases with secondary infection. No patient was admitted to treatment until all members of his family or all persons living with him had been examined. Cases in which the diagnosis was doubtful were treated. After diagnosis each patient was given a leaflet embodying the necessary information—namely, to bring a change of underwear to the treatment centre and to disinfest, by boiling, his bedding and underwear after coming home from the treatment. Patients who seemed to be unsuited to the treatment at the centre because the scabies was too far advanced or they had a dermatitis, etc., and all children under the age of 10 were taken into the hospital and treated, according to age and clinical signs, with Wilkinson's ointment or with sulphur ointment. This treatment lasted from three to seven days. Infants were taken in with their mothers. One of the principal rules was to treat the whole family at the same time.

The treatment used at the Vienna scabies centre compared with modern cures (rotenone, benzyl benzoate) had the disadvantage that it could not be done at home and that it

took a few hours' time. Working men had usually to take a day off. Its advantages were that only one treatment was necessary and that the drugs used were cheap and easily obtainable. Provided the cases were carefully selected the number of recurrences was small.

There were many reinfections, caused chiefly by the fact that not all members of the family were brought for examination or that the directions about disinfestation of bedding, etc., were not obeyed. A close co-operation with a social welfare centre would be of the greatest value to overcome these difficulties. It ought to be especially stressed that group examination and group treatment, disinfestation, and improvement of housing conditions are the most important factors in dealing with a scabies epidemic. The mere treatment of single cases, however effective the treatment might be, will never be sufficient to extinguish the epidemic. Simultaneously with the scabies epidemic among men there was a scabies epidemic among animals, first among horses. There were many cases of scabies among cats, goats, etc. From grazing goats scabies was transmitted to chamois and did considerable damage among game in some districts of the Alps. The animal scabies was interesting; even as late as 1930 people were infected with scabies from their pet cats. The signs of scabies transmitted from animal to men are different from the ordinary scabies and the diagnosis is often difficult. Reinfection occurs till the source—for example, the infected cat—is treated too.—I am, etc.,

Belfast, May 8. A. FESSLER.

Physical Medicine, Orthopaedics, and the Services

SIR,—The controversial views which pervade both your annotation of April 26 (p. 633) and the letters in the correspondence columns criticizing this make it clear that all is not well with the status of physical medicine. In its present form it appears to be no more satisfactory to the physiotherapists than acceptable to his colleagues—the orthopaedist in particular. That this should be so could not possibly come as a surprise to anyone who has watched the trend of events over a period of years. The truth is that the physiotherapist of to-day occupies an untenable position inasmuch as he desires to rank as a universal clinician specialized in a particular group of therapeutic measures. Such a combination invites suspicion and must result in his extinction.

From the letters signed by some orthopaedic surgeons (May 24, p. 791) it is obvious that physiotherapy is looked upon by them as their own rightful "sphere of influence." Such a conception also has objectionable features, for it would lead to a monopoly which might create an anomalous situation such as a gynaecologist having to refer cases requiring intrapelvic diathermy to the orthopaedic department for this type of treatment.

The only other alternative is one where the medical man whose main interest is in the development of physical methods assumes a position somewhat similar to that of the pharmacologist, his programme being the application of physical principles to the diagnosis and treatment of pathological conditions. This, of course, implies investigation of the action of physical agents and the elaboration of technique and posology. For such an ambitious scheme to be successful a number of conditions would have to be satisfied. The physiotherapists, who incidentally should have made a thorough study of physics and mechanics, would have to be in charge of physiotherapy departments in hospitals so as to have access to the clinical material essential to the advancement of this science. At the same time some degree of decentralization should obtain as regards the treatments which have been accepted as valuable, for which the indications are clear-cut, and of which the technique and posology have been established. The importance of close and continued collaboration between the physiotherapist and his colleagues cannot be sufficiently stressed, since without this a wholesome critical element of the patient's progress would be wanting.

It is not possible in a letter of this type to embrace every facet of what must be considered a revolutionary idea, but I feel that such a change would be for the better and would put an end to strife, which must otherwise continue on account of the insoluble nature of the problem.—I am, etc.,

London, W.1, May 26. P. BAUWENS.

SIR,—The recent correspondence in your columns discusses and criticizes the work and status of physical medicine. Some orthopaedic surgeons and others claim that physical medicine should be ancillary to the field of orthopaedic surgery and should be controlled by them with the help of technicians or similar personnel.

It must be recorded that the apparatus and agents employed in physical medicine have biological or physiological actions which include: (1) the counteraction of shock; (2) analgesia and relief of pain; (3) the production of heat, including fever —that is, artificial pyrexia; (4) augmentation of the capillary circulation—counter-irritation; (5) stimulation of metabolism, vitamins, and cell growth; (6) bactericidal effects and surface sterilization; (7) the increase of local and general immunity, prophylactic measures (preventive medicine); (8) the excitation of movement, massage, physical exercise, manipulation, rehabilitation, etc.; (9) psychological effects. These reactions can only be successfully obtained by the training and employment of skilled physicians, who have obtained specialized knowledge of the most suitable apparatus or agent necessary, of the method of application of that apparatus or agent, and of the dosage to be administered by the qualified personnel under their supervision.

Only 10% of the work of physical medicine falls within the scope of the orthopaedic surgeon; about 35% is devoted to the treatment of rheumatic diseases and arthritis, etc.; the remainder is equally divided between the dermatologist, the gynaecologist, the neurologist, and others. It is impossible to conceive the true position of physical medicine as one which is ancillary to orthopaedic surgery alone. In support of Sir Morton Smart's remarks (May 24, p. 792), the position of the orthopaedic surgeon is little different from that of the neurologist, the ophthalmic surgeon, or other specialized department which needs to employ physical medicine. The ideal method must be co-operation between the physiotherapeutist and the personnel under his supervision. The system by which the general practitioner, physician, or surgeon refers his cases to the department of physiotherapy (usually accompanied by inadequate prescription) must have serious deficiencies. In practice the treatment is left to the discretion of the technician or personnel attached to this department. With the best will in the world they cannot give full justice to the patient or obtain the results to be expected from the help and advice of the specialist. The fallacy of such methods is seen in the administration of prophylactic treatment to industrial workers in factories. The general adoption of such policy must finally lead to the complete disappearance of the specialist in physical medicine, since he cannot survive without the recognition of his special knowledge or without support from his colleagues.

In my own opinion manipulative treatment should be carried out solely by orthopaedic surgeons; after-treatment may need the correct co-operation between the orthopaedic surgeon and the physiotherapist.

The present position of physical medicine is unhappy and does not encourage special training or specialization. The department of physical medicine usually treats a high percentage of the total number of patients who attend the outpatient department, but often it has no working specialist. Too much is left to the discretion of the technician, and as a result treatment is often inadequate, disappointing, or unduly delayed. It is practically impossible for the consultant in physical medicine to give his service to more than one or two hospital departments. His work calls for regular attendance in the department for many hours so that he can supervise the treatment carried out by the personnel; it is frequently necessary for him to carry out the treatment himself. Full collaboration with his colleagues is essential, and in special cases the combined effort is needed—for example, in conditions affecting the larynx or the eye, and in gynaecological cases. I hope that in the near future all departments of physical medicine will be directed by an actively working consultant specialist, who will devote regular and adequate time to his duties; in addition, the teaching of nurses and training of students and doctors must be organized. I cannot see any future for specialization or the successful organization of the work of physical medicine unless such plan and programme are rapidly supported.—I am, etc.,

London, W.1, May 26. ALBERT EIDINOW.

Medical Planning Commission

SIR,—I have noticed, with some little regret criticism of the Medical Planning Commission. This commission does represent all that is best in our profession, and we should be grateful to its members for giving up so much of their time to work from which they can derive no possible personal benefit. Much has been said and much written lately on the establishment of a State Medical Service, but whether or not such a service shall be established is for Parliament and not for us to decide. All that we can do is to attempt to safeguard the advancement of medicine and the interests of our patients and protect our own professional life. We have learned during recent months from bitter experience what dire results panic legislation can have, and it is undoubtedly in the national interest that the future of medicine shall be discussed now so that we may not be caught unprepared in a difficult post-war period. It is to be hoped that the Medical Planning Commission and the medical profession generally will see the terrible dangers of the deification of the State—this dread paganism which is overrunning the world, a paganism more dangerous and more evil than any previously known in the world's history, a paganism which is demanding for its god—the State—human sacrifice on a scale hitherto undreamed of.

Much of the influence exercised by the Church has passed away, but medical practitioners individually and collectively still do exercise some influence on public opinion, and the Medical Planning Commission will have to face and consider great sociological problems affecting the lives of millions.

It is the plain duty of all who wish to see a better world for the next generation to give their utmost support and assistance to this commission.—I am, etc.,

JOHN ELIOT

New Barnet, May 25.

Obituary

DUGALD REVIE, M.B., C.M., D.P.H.

The death occurred at Dumfries on May 13 of Dr. Dugald Revie, who had been for many years a well-known figure in Newcastle-upon-Tyne and Northumberland B.M.A. circles.

Born in Glasgow (writes "W. S.," a pupil and admirer) as long ago as 1862, Dr. Dugald Revie was until quite recently the moving spirit of the Morpeth Division of the B.M.A., and engaged in active general practice until a few weeks ago. He received his early education at the George Square Academy, Glasgow, and went on to Glasgow University, where he graduated M.B., C.M. in 1889. In the same year, after a theological course, he was ordained a minister of the United Free Church of Scotland, and sent to India as a medical missionary. He spent twenty very fruitful years (1889-1909) at Wardha, Central Provinces, doing a great work during the plague which ravaged those districts in 1898. For this he received Government recognition, as also for the devoted work he did for the leper asylum at Wardha during the years 1894-1909. Dr. Revie entered into the municipal life of his district (as well as being guide, philosopher, and friend to the people in his capacity as missionary) by serving as vice-chairman of Wardha Municipality 1891-1900, and chairman 1900-4.

After twenty years' service in India Dr. Revie retired to the homeland on account of his wife's health, and began a second long and useful career in this country. He practised at Blairgowrie in Perthshire for about three years, taking in 1912 the St. Andrews D.P.H. and becoming M.O.H. of the neighbouring district of Rattray with the control of Strathmore Hospital 1910-13. Dr. Revie bought a practice at Ashington, Northumberland, in 1913, and gave his services in a voluntary capacity, as captain in a Northumberland Field Ambulance to the R.A.M.C., acting also as a surgeon attached to Ashington Hospital during the last war. He quickly identified himself with medical and medico-political activities on the Northumberland coalfield, and soon became a force in North-Eastern B.M.A. circles, being instrumental in carrying out agreements between the doctors and the miners' lodges on various occasions. It was largely due to Dr. Revie's influence that the Ashington Public Medical Service was founded in 1927. Of this very successful venture he was honorary secretary until his death. He served the Morpeth Division of the B.M.A. in many capacities from 1914 to the present time, being hon. secretary from 1931 to 1938, when he retired on account of failing health. He acted as delegate at several Representative Meetings of the B.M.A., his advice being often asked on medico-political and medico-ethical subjects by doctors in Newcastle-upon-Tyne and Northumberland. He was also a member of the Northumberland Panel Committee and an authority on N.H.I. matters. His last public service was as hon. secretary of the Morpeth (Northumberland) Local War Committee, which post he held from 1938 until his death. In addition to being universally beloved as a family physician in his adopted district, Dr. Revie was well known and respected in Church circles, especially amongst North of England and Scottish Presbyterians. He had the unique distinction of holding a seat in both English and Scottish Presbyterian Assemblies. He used to recall as one of his pleasantest memories his taking part in the historic march through Edinburgh at the time of the Union of the United Free Church with the Established Church of Scotland in 1929.

JOHN W. C. GUNN, M.A., M.B.

Professor of Pharmacology, University of Capetown

We regret to announce the death on May 4 of Dr. John William Cormack Gunn, professor of pharmacology and dean of the faculty of medicine in the University of Capetown. During his early years in South Africa he had been honorary secretary of Cape of Good Hope West Branch of the British Medical Association, and at the Centenary Meeting in London in 1932 he was vice-president of the Section of Pharmacology and Therapeutics.

John Gunn, like his elder brother Prof. J. A. Gunn, M.D., of Oxford, was a native of Kirkwall, Orkney, where he was born on January 29, 1889. From Kirkwall Burgh School he went to the University of Edinburgh and distinguished himself as a student, winning the Neil Arnott Prize on graduation as M.A. in 1908. He took the M.B. and Ch.B. degrees in 1912, and after some months as assistant in materia medica in the University laboratory at Edinburgh was appointed assistant in the Department of Pharmacology at University College, London. He held that post for six years and then went to Belfast as lecturer in pharmacology at Queen's University, and taught there until his election in 1919 to the chair of pharmacology at Capetown. During the last war he served in Egypt as officer in charge of the Medical Division of the 19th General Hospital at Alexandria with the temporary rank of major R.A.M.C., and was mentioned in dispatches.

Besides his work as professor of pharmacology and dean of the faculty of medicine at Capetown Prof. John Gunn undertook the duties of curator of the Wernher and Beit medical laboratories and head of the Medical Students' Residence. He published several papers on pharmacological subjects in the *Journal of Pharmacology* and the *Transactions of the Royal Society of South Africa*.

H. O. NICHOLSON, M.D. Aberd., F.R.C.P.Ed.

Past President, Edinburgh Obstetrical Society

Dr. Harry Oliphant Nicholson died at a nursing home in Edinburgh on May 26. The second son of Prof. H. Alleyne Nicholson, M.D., D.Sc., who held the chair of natural history in the University of Aberdeen, he was born on March 13, 1870, and from Gordon's College went to study medicine at his father's university, where he graduated M.B., C.M. in 1891, and was awarded highest honours and the Strathcona Prize for his M.D. thesis some years later. His early clinical experience was gained as house-physician and house-surgeon at the Royal Hospital for Sick Children, Aberdeen. This was followed by post-graduate obstetrical work in Berlin. He then practised for eight years at Kirkcaldy, moving at the end of the century to Edinburgh, where he spent the rest of his life.

Dr. Oliphant Nicholson was made a Fellow of the Royal College of Physicians of Edinburgh in 1904, by which time he had been appointed to the staff of a number of medical institutions. For twenty years he worked as senior assistant physician to the Royal Maternity Hospital, retiring in 1924. He was also lecturer on clinical obstetrics in the University of Edinburgh, and examiner in midwifery at his own university and for the Scottish Midwives Board. Dr. Nicholson was a

popular teacher, with a gift for imparting the practical side of his subject. Throughout his working life he combined general practice with the specialties of midwifery and gynaecology. As a colleague has written in the *Scotsman*: "He represented the type of practitioner who in some ways is characteristic of one of the most attractive aspects of Scottish medicine—the family doctor who plays a multitude of parts." He was a kind and generous man, devoted to his patients, and in turn they looked upon him as their friend. He had been a member of the British Medical Association for nearly fifty years.

SIR D'ARCY POWER

Dr. J. D. ROLLESTON writes:

The excellent survey of Sir D'Arcy Power's life and work in the *Journal* of May 31 (p. 836) contains one slight error and two omissions. The International Congress held in London in 1913 was an International Congress of Medicine and not an International Historical Congress as stated by the writer of the obituary, though its Section XXIII, to which Sir D'Arcy contributed a paper on the lesser writings of John Arderne, was devoted to the history of medicine. The International Congress of the History of Medicine held in London, of which Sir D'Arcy was vice-president of honour and I was general secretary, did not take place until 1921. The omissions, which are not unimportant, as they are concerned with Sir D'Arcy's interest in public health, are as follows. First, there is no mention of his having been a nominee of the Ministry of Health on the Metropolitan Asylums Board from 1921 to 1927, during which period he served as chairman of the Pinewood Sanatorium, Medical and Nursing Subcommittee, and member of the Tuberculosis Subcommittee, Infectious Hospitals Committee, and North-Western Hospitals Subcommittee. Secondly, some mention should surely have been made of his interest in venereal disease, on which he gave evidence before a Royal Commission as representative of the Royal College of Surgeons and the Royal Society of Medicine in 1914, and contributed many articles to periodical literature, as well as being co-editor with J. Keogh Murphy of a *System of Syphilis*.

We regret to announce the death by enemy action of Dr. R. EDMUND SYMES-THOMPSON at the early age of 28. The son of Dr. H. E. Symes-Thompson, consulting physician to the Royal Chest Hospital, and grandson of the late Edmund Symes-Thompson, M.D., F.R.C.P., Richard Edmund studied medicine at Cambridge and at St. George's Hospital, graduating B.A. in 1934 and taking the M.R.C.S. and L.R.C.P. diplomas last year. At St. George's he won the Sir Charles Clarke prize and the Thompson medal, and since qualification he had been resident anaesthetist there and house-physician at St. Luke's Hospital, Chelsea.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The Committee for Medical Radiology and Electrology has fixed dates for the D.M.R. and E. examinations in 1942 as follows: Part I, February 10 and July 8; Part II, July 7 and October 6.

At a Congregation held on May 24 the following medical degrees were conferred:

M.B., B.CHIR.—(By proxy) I. B. Mackay, A. R. P. Ellis.

UNIVERSITY OF EDINBURGH

The University Court has approved the following recommendations of the Faculty of Medicine:

(1) That psychiatry be added as a subject in the final professional examination in medicine in the fourth year: a written paper and an oral examination, conducted by the professor and lecturer, with an external examiner.

(2) That candidates for the Diploma in Medical Radiology be required to have had at least two years' postgraduate experience: six months as resident surgeon in a hospital and eighteen months' general clinical experience; and that it is desirable that they should have had postgraduate experience in morbid anatomy and morbid histology.

The Services

CASUALTIES IN THE MEDICAL SERVICES

ROYAL NAVY

Surgeon Lieut. IVOR MCNEIL DRYSDALE, R.N., was killed on active service in March. He was the youngest son of the late Mr. Drysdale and Mrs. Drysdale of Glasgow, was educated at the University of Glasgow, where he graduated M.B., B.Ch. in 1935, and entered the Royal Navy in 1936. He leaves a widow.

Surgeon Lieut. JAMES OXENHAM FIELDING, R.N., was killed when H.M.S. *Hood* was sunk last month. He was the only son of Dr. and Mrs. S. J. Fielding of Norwich, and was educated at Queens' College, Cambridge, and St. Thomas's Hospital, qualifying M.R.C.S., L.R.C.P. in 1938. He had held the posts of clinical assistant in the ophthalmic, psychological medicine, and ear, nose, and throat departments, and senior ophthalmic house-surgeon, at St. Thomas's Hospital before entering the Royal Navy in 1938. He leaves a widow. He was a member of the British Medical Association.

Wounded

Temporary Surgeon Lieut. Alexander Watt, R.N.V.R.

ROYAL ARMY MEDICAL CORPS

The death is reported on active service in the Middle East in May of Captain DONALD STARR. He was the only son of Mr. and Mrs. J. Starr of Wigan and graduated M.B., Ch.B. of the University of Manchester in 1926. He had held the posts of house-surgeon at the Manchester Royal Infirmary and medical officer at the Kent County Mental Hospital, Chartham Down. He leaves a widow. He joined the British Medical Association in 1928.

Lieut. ALASTAIR HAIR died in April of wounds received in action. He was the elder son of the Rev. James and Mrs. Hair of Edinburgh, and was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1931. He resided in Edinburgh for a time after graduation and then moved to Presteigne in Radnorshire until 1935, when he was appointed medical officer of health for Llandrindod Wells.

Medical Notes in Parliament

Diphtheria Immunization

In a reply on May 29 to Prof. Hill, Mr. BROWN said it was estimated that if three-quarters of the number of children at each year of age below 15 were immune against diphtheria and this level were maintained year by year the disease would be practically abolished. It would be premature to forecast the result of the steps now being taken to promote immunization. He trusted the good sense of parents would in the great majority of cases lead them to secure for their children this vital protection.

Answering Mr. Leach on the same date, Mr. BROWN said the number of deaths from diphtheria in the 126 great towns during the first quarter of 1941 was greater than in the corresponding periods of 1939 and 1940. The number of notifications in the same period was greater than in the first quarter of 1940, but less than in the first quarter of 1939. He had no figures, as yet, to show the increase in the number of children immunized during the first three months of 1941. This could not be related to the total of deaths from diphtheria in persons of all ages. Nor could the effects of the disease over a short period be related to the number of inoculations carried out in that same period, immunization being essentially a prospective and long-term safeguard. He was not aware of any facts which suggested that immunization caused outbreaks of diphtheria, but there was ample evidence that in places where it had been widely applied to children under 15 the disease had been practically eliminated.

Hospital Physiotherapy Departments

General Sir GEORGE JEFFREYS asserted that there were hospitals staffed with one or more masseuses acting under the direction of surgeons who had no specialized training in this branch of medicine, and that physiotherapists were appointed to the staffs of hospitals only in the event of an application being made for such an appointment by the medical superintendent of the hospital. He asked Mr. Brown to direct that physiotherapists be appointed whether the medical super-

intendent applied or not. Mr. BROWN said on May 28 that the policy of advocating the provision of physiotherapeutic departments in all Class I hospitals with 300 or more casualty beds was announced in a circular of June 25, 1940, and in subsequent statements. The existing methods of staffing these departments were generally satisfactory. His department had in a number of cases invited hospital authorities to consider the appointment of physiotherapists. It would not be wise to insist upon such appointments against the wishes of the clinical staff of the hospital. No alien physiotherapist had yet been appointed to a post under the Ministry.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

With the exception of measles, the incidence of all the common infectious diseases decreased during the week. The notifications of measles, which fell by nearly 3,000 in the previous week, rose by 989. The increase was fairly general throughout the country, the returns from Buckinghamshire, Herefordshire London, and Sussex being the highest of recent weeks. In Scotland the notifications were less than half those for the preceding week, which had been exceptionally high Edinburgh is the only area which did not report a decrease

Whooping-cough

The notifications of whooping-cough for the counties of England and Wales showed only minor fluctuations from the totals returned for the preceding week The relatively large rise in the prevalence of the disease in Buckinghamshire Durham, and Suffolk West was contributed by the rural districts; the increase in Essex was general throughout the county. In Glasgow 403 fresh cases were notified during the week, as compared with 714 in the preceding week

The notifications of scarlet fever in England and Wales declined by 47 and by 43 in Scotland Approximately one-seventh of the total cases were recorded in Lancaster

Diphtheria

The fall in the northern region, and Wales was responsible for the decrease of 73 in the notifications of diphtheria; the tendency was to an increased incidence in other parts of the country. The lowest figure—171—of recent months was recorded in Scotland. The intensive drive by the Ministry of Health for immunization against diphtheria has been well supported by local medical officers, and their reports show that a large number of children have already been treated

Enteric Fever

Forty-one cases of enteric fever were notified in England and Wales, a reduction of 9 compared with the preceding week From the scattered outbreak in Middlesex 17 fresh cases were recorded, an increase of 4. The next largest total was received from Lancaster, 7, an increase of 5 cases The total of 40 cases reported from Scotland was 9 below that of the previous week. Dundee, with 27 cases, is still the principal centre of the disease.

Dysentery

The incidence of dysentery declined by one-third in England and Wales during the week reviewed. A further 8 cases were notified in Lancaster, Whiston R.D., and in the two London outbreaks 7 new cases occurred in Islington and 10 in Wandsworth. A decrease of 8 was recorded in notifications from Scotland, but in the city of Aberdeen the figure rose from 7 to 12.

Cerebrospinal Fever

The number of new cases of cerebrospinal fever notified in England and Wales during the week was 266, a decrease of 61 on the total of the preceding week, and was the lowest weekly total since the second week in January. Small increases were reported in some areas; the highest of these was 6 and was recorded for Cheshire and Devonshire. In London there were only 16 notifications, as compared with 37 in the preceding week. In Scotland 65 cases were notified during the week, an increase of 28 compared with the preceding week. The largest returns were from Glasgow, 20; Edinburgh, 9; and the County of Ayr, 8; the remaining 28 were from twenty-two areas.

Typhus Fever

An outbreak of typhus fever was reported as occurring on May 17 in the Clogher district of West Clare One death has occurred.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 10.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland

A dash — denotes no cases, a blank space denotes disease not notifiable or no return available

Disease	1941 (a)	(b)	(c)	(d)	(e)	1941 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

Medical News

Mr. F. C. R. Douglas, M.A., M.P., Chairman of the Housing Committee of the L.C.C., will read a paper on "Economic Aspects of Soil Fertility and Nutrition" before the Royal Society of Arts on Wednesday, June 11, at 2.30 p.m., at the Institution of Electrical Engineers, Savoy Place, Victoria Embankment, W.C.

A meeting of the Section of Proctology of the Royal Society of Medicine will be held on Wednesday, June 11, at 5 p.m., for a discussion on "Factors which make for Safety in the Pre-operative and Post-operative Treatment of Carcinoma of the Rectum," to be opened by Prof. E. R. Flint, Surgeon Rear-Admiral G. Gordon-Taylor, Dr. Cuthbert Dukes, and Mr. C. Naunton Morgan.

The B.B.C. announces that on Friday, June 13, at 10.15 p.m., "Blitz Doctors," a programme of incidents in the life of the Emergency Medical Services in wartime, will be heard in the Home Service. This is based on material collected by a doctor. The programme, divided into four parts, tells the story of the "doctors of the blitz" (medical men, nurses, ambulance drivers, stretcher-bearers) from their inception through the earlier war days, through the arduous waiting period right down to the moment when they went into action. The programme has been prepared in consultation with medical personnel who have been in the blitz since it started.

A meeting of the Bristol Division of the B.M.A. will be held in the Physics Lecture Theatre at the Royal Fort, University of Bristol, on Thursday, June 12, at 3.30 p.m. All members of the Association and medical non-members will be welcome. A symposium has been arranged on "Experiences of First Aid in Air Raids." Dr. J. N. Nixon, chairman of the Division, will preside, and Dr. H. M. Golding will open the discussion, followed by Prof. R. H. Parry, M.O.H. Bristol, and eight other medical men. Tea will be served after the meeting. Those intending to stay for tea should inform the hon. secretary, Dr. J. A. Hooker, before June 10.

Dr. I. Frost has been appointed medical secretary to the British Social Hygiene Council—the position recently vacated by Sir Drummond Shiels, who is now devoting his whole time to his work on the Empire Parliamentary Association, but remains the Council's medical adviser.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Post-herpetic Neuralgia

"M.B., B.S." writes: I am at present attending an elderly gentleman who is suffering from severe post-herpetic neuralgia following an attack of herpes zoster affecting his cervical plexus. I shall be grateful for hints regarding any treatment which is likely to relieve his pain. The worst of the pain actually seems to have passed off, but the relatives are anxious that something further should be done. Would any of the forms of physiotherapy or electrotherapeutics be of any use in these cases?

Treatment of Night Sweats

"J. R. E." writes: Has "J. N. T." (March 8, p. 389) considered the possibility of undulant fever?

Income Tax

Cost of Board and Lodging of Assistant

"P" claims to deduct £2 per week in respect of a locumtenent, but the inspector of taxes considers £1 per week to be sufficient. Has he a good case for appeal to Commissioners?

* * So much depends on the precise facts of each case that * it is difficult to advise. Certainly £1 a week seems a low estimate to cover not only cost of food but also the locumtenent's share of domestic service, rent and rates, light and heat, etc. We think "P" may have a good chance of increasing the £1 per week on appeal, though the Commissioners might not go so far as to allow £2 per week. If there are no special circumstances we should advise an appeal unless the Inspector is prepared to compromise at, say, 30s. or 35s. per week.

LETTERS, NOTES, ETC.

Evening Temperatures and "Midsummer Time"

Dr. W. H. PALMER (Hayle, Cornwall) suggests that the present two hours' difference between clock-time and sun-time may be leading to many errors where the old times of taking evening temperatures are adhered to. He writes: A preliminary test of this theory, in both private and hospital practice, has shown that quite a proportion of cases have not actually reached the end of their febrile stage, though the charts (kept at clock-time) indicate that they have. In some cases—for example, operation for appendicitis and peritonitis, mucopurulent bronchitis in elderly patients—there was as much as two degrees' difference between the 6.30 and 8.30 evening temperatures, and it is just in these cases that getting up too soon may have unfortunate results. Not having seen or heard this subject referred to as yet, I am drawing attention to it in case others would like to make some comparative tests for themselves.

Opalescence of the C.S.F. after Sulphapyridine

Dr. W. LEES TEMPLETON (London, N.6) writes: Some time ago I reported a peculiar opalescence of the cerebrospinal fluid in cases of pneumococcal meningitis during the administration of sulphapyridine. In each case nothing abnormal was then present in the fluid, but the appearance on naked-eye examination was disconcerting when seen for the first time. Drs. D. F. Johnstone and P. Forgacs (May 24, p. 772) describe the same appearance. One wonders if the pathologists have any explanation for this phenomenon and if it is present in any other condition. Incidentally, with reference to the article mentioned in which cerebral symptoms are, it is suggested, produced by the drug, might I be allowed to point out that, if it is so, then it would seem to support the view that in meningitis sulphapyridine may act by virtue of its homoeopathicity—in other words, that the drug which can produce symptoms may in smaller doses cure the same condition.

Hips and Vitamin C

Mr. A. V. WADSWORTH writes: Quite an interesting correspondence has been taking place on the above subject. No one seems to have gone into the question of the true vitamin C content of rose-hips confection. Last year I made from the hips of *Rosa rugosa* a confection by the following method. The ripe hips were boiled with a little water and strained through a sieve, an equal quantity of sugar was added, and the whole boiled until it formed a jelly on cooling. This made a very pleasant confection. The vitamin C content of the pulp of the original rose-hips was equivalent to 777 mg. of ascorbic acid per 100 grammes, and that of the final conserve was equivalent to 378 mg. of ascorbic acid per 100 grammes. These figures are far in advance of the vitamin content of the much-vaunted orange, and there is no doubt that as a source of vitamin C rose-hips cannot be ignored. The pulp of the very large hips of the *Rosa rugosa* can be eaten when ripe; it has a pleasant flavour of tomatoes. Two of these are practically equal to an orange.

Lobar Pneumonia at 100: Recovery

DR. C. E. H. MILNER (Reigate) writes: A spry and voluble old Dublin lady of a hundred summers (who says she has had two attacks of pneumonia in the past) had a rigor six days ago, and was found to have a temperature of 102.4° F. Pulse and respiration were not unduly hurried—92 and 24. Marked dullness was discovered at the left base, and the diagnosis of lobar pneumonia was obvious. The only treatment was by sulphapyridine, 1 gramme four-hourly, together with 2 drachms four-hourly of John Jamieson's best. The result was dramatic. The temperature fell, step by step, during twenty-four hours to the normal line; pulse and respiration also. Physical signs only now became elicited by auscultation, and the whole of the left lower lobe was found to be consolidated. Recovery in six days is complete, and the patient's appetite is voracious.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JUNE 7 1941

General Council of Medical Education and Registration

PRESIDENT'S ADDRESS

In his opening address to the one hundred and fifty-third session of the General Medical Council, which met at the house of the Royal Institute of British Architects on May 27, Mr. T. L. EASON, the president, referred to the damage to the Council's premises through enemy action. The material loss, he said, was much less than might have been expected in the circumstances. The Royal Institute of British Architects had extended their hospitality not only to the Council but also to the officers of the Council and of the Dental Board. Moreover, they had found room for the material without which the business of both bodies as registration authorities could not be carried on for a day.

It would be the pleasure of the Council that he should convey to Sir Ian MacAlister, the secretary of the Royal Institute, and through him to his colleagues, a warm expression of the Council's appreciation of all that he and they had done at a critical moment.

Personal Matters

Mr. Eason continued:

Since we met in November Prof. Robert Howden who represented the University of Durham on the Council from 1918 to 1928, has died. When he first took his seat among us he was welcomed by the President as "the accomplished editor of Gray's *Anatomy*," and the minutes show that when he retired from our ranks ten years later he had become a familiar friend and had been a loyal helper in our business.

I am sure that all the members of the Council will hear with the deepest regret that, owing to grave illness, Sir Norman Walker has found it necessary to resign his seat on the Council. When he retired from the presidency in November, 1939, I expressed the hope that we might have his advice and counsel for many years to come. That hope has not been fulfilled, and we shall all regret that Sir Norman's long and distinguished services to the Council have now so sadly come to an end. Sir Norman Walker sat on this Council as a direct representative of the registered medical practitioners of Scotland, and by the provisions of the General Medical Council (Temporary Provisions) Orders, 1940, any vacancy in the office of a direct representative is to be filled by the election, as soon as conveniently may be, of a successor by the Council. It will be our duty, therefore, at a later stage in this session, to elect a direct representative to fill the vacancy caused by Sir Norman Walker's resignation. The person so elected will hold office until December 31, 1941.

His Majesty, with the advice of his Privy Council, has been pleased to nominate Professor Lowry to take the place of the late Colonel Thomas Sinclair. This translation of a colleague and friend from the representation of the Queen's University, Belfast, to the position of Crown nominee for Ireland involves the appointment of a new representative of the University.

Supply of Students and Practitioners

The Council will note with satisfaction that in the Schedule of Reserved Occupations as revised in April it is provided that all persons who have been admitted, or duly accepted for admission, as students by recognized medical schools shall be reserved. It is, however, a condition of their reservation that, except in the clinical years, they shall join a Senior Officer Training Corps or an Air Training Squadron, or undertake some alternative form of national service approved by the university authorities, and that their reservation is subject to periodical certification of satisfactory progress in their studies. Medical schools are also to undertake not to admit, in ordinary circumstances, a quota of students higher than the average entry for the three years preceding the war. It will be possible, therefore, to maintain the supply of medical practitioners at its normal level. Meanwhile the Medical Register for 1941 shows that there were 1,319 more registered medical practitioners at the end of 1940 than there were at the end of 1939. The number of persons added by registration to the Register was 584 less in 1940 than in 1939, but this reduction was primarily due to a fall of 410 in the number of registrations in the Colonial and Foreign Lists.

With the object of using to the best advantage the professional services of volunteers from the Empire outside the United Kingdom, or from Allied or friendly countries, and of friendly refugees from enemy countries, a new Order in Council—the Medical Register (Temporary Registration) Order, 1941—has been made since the last meeting of this Council. Under Defence Regulation 32B and this Order the Council may register temporarily in the Colonial or Foreign Lists of the Register practitioners from the following territories: (i) The several States and territories of the Commonwealth of Australia, Burma, the several Provinces of the Dominion of Canada (to which the Order of 1940 also applied), India, Newfoundland, New Zealand, and the several Provinces and territories of the Union of South Africa; (ii) His Majesty's Colonies, Protectorates, and Mandated Territories; (iii) Belgium, Czecho-Slovakia, France, Greece, Holland, Norway, and Poland; and (iv) Germany and Italy.

The President then reminded the Council of the prescribed conditions for registration under this Order.

The numbers of practitioners who had at the end of last week been registered by virtue of Imperial qualifications granted outside the United Kingdom was 44, and by virtue of qualifications granted in the United States of America or in Continental countries 250, of whom 20 were serving in the Armed Forces, and 230 were in civil employment approved under the Order of 1941. More recently Mr. Roosevelt, in response to a telegram sent to the American Red Cross, of which he is president, has appealed for 1,000 young American doctors to volunteer for professional service either in the Armed Forces of the Crown or in the civilian Emergency Medical Service, an appeal to which there has already been a splendid response.

Another instance of the sympathy of the United States with the difficulties which may beset medical students in schools which have been damaged in air raids is the offer of the Rockefeller Foundation to provide a two-years course of clinical instruction free of cost in medical schools of repute in the United States or Canada for twenty-five selected candidates. This offer has been gratefully accepted, and a committee presided over by the Chairman of Business will shortly be making the necessary selection from among the applicants. A number of licensing bodies have already agreed that the studies which they pursue during their two years' absence will be recognized here as part of the curriculum. The Council has intimated that it will raise no difficulty to this.

Medical Reciprocity

The severance in October of the reciprocal relations between the United Kingdom and Italy has set us free to make it known that the view of the law on which an important provision of the Anglo-Italian agreement of 1925 as to professional practice in the two countries was founded has since proved to be mistaken. The view which in 1925 had prevailed since 1886 was that every practitioner whose name was in the Medical Register was a registered medical practitioner of the United Kingdom. The later, and the authoritative, view is that only practitioners registered by virtue of qualifications granted in the United Kingdom or in Eire are registered medical practitioners of the United Kingdom. That is to say practitioners registered in the separate lists of Colonial and foreign practitioners in the Register in pursuance of Section 14 of the Act are not registered medical practitioners of the United Kingdom, and no territory is required to afford privileges of practising to Colonial or to foreign practitioners as a condition of the establishment or maintenance of reciprocal relations between that territory and the United Kingdom.

Certificates by Practitioners

It has recently been made to appear to me by informati and evidence received from competent authorities that i

number of instances there has been a relaxation of the vigilance with which certificates are being signed. I have therefore, after consultation with the Penal Cases Committee, issued, on behalf of the Council, an announcement in the medical press drawing attention of registered medical practitioners to the terms of the Warning Notice issued by the Council with regard to the granting of medical certificates. (See *British Medical Journal*, April 19, 1941, p. 600.)

EDUCATIONAL BUSINESS

Colonel H. L. TIDY, chairman of the Education Committee, stated that a complaint had been received, through the Secondary Schools Examination Council, from the Joint Committee of the Associations of Headmasters and Assistant Masters and Headmistresses and Assistant Mistresses, concerning the action of certain medical schools in allowing only a limited number of students who had obtained exemption from the first medical examination on the result of the higher school certificate to enter second-year courses. The Examinations Council had been given to understand that the difficulty was largely one of the existing pressure on accommodation at medical schools. The complaint stated that candidates wishing to pursue a medical course were being advised to enter the medical schools so soon after matriculation as their age allowed and to take the first-year courses there instead of remaining at school for two more years to take the higher certificate with a view to obtaining exemption from the first medical examination. The masters and mistresses viewed this tendency with much concern because the withdrawal of intending medical students from the schools soon after matriculation must inevitably have a harmful effect upon sixth-form science work. The medical schools, moreover, recommended that between matriculation and entry to the University intending medical students should pursue courses of study in subjects other than those bearing on their medical studies in order to acquire a general cultural and educational basis on which to build their medical education. The masters suggested that the medical schools had overlooked the fact that in hard times pupils would not wish to stay at school to take a course which bore no relation to their future studies, nor would they wish to offer for the higher school certificate examination, particularly if they were candidates for State scholarships, subjects in which they had no special interest. There was no valid reason, in the opinion of the masters' association, why the medical schools should bring pressure to bear upon candidates to adopt an alternative procedure which would not only involve them in greater expense but would induce them to enter college at an earlier age than was desirable.

The Education Committee of the Council, after considering the matter, felt that it was not one in which any intervention on the part of the Council was called for, but trusted that compliance would be secured with the recommendations of the Council in regard to preliminary general education which had been in operation since 1938.

The Council endorsed this view.

The report of the Examination Committee, presented by Dr. R. J. BROCKLEHURST, consisted of a summary of the annual returns of professional examinations held in 1940. The highest percentage of passes at the final examinations in medicine was at St. Andrews (90.32), and the lowest at Cambridge (59.41); the highest in surgery was also at St. Andrews (95), and the lowest at the Apothecaries' Society of London (42.86).

The Public Health Committee, under the chairmanship of Mr. JOHN RITCHIE, embodied observations of the Universities of Durham and of Glasgow on the report on the visitation made by representatives of the Council of examinations for diplomas in sanitary science, public health, and state medicine.

The Pharmacopoeia Commission

Dr. DAVID CAMPBELL, chairman of the Pharmacopoeia Committee, presented a report from the British Pharmacopoeia Commission concerning the work done during the past six months, which had been concerned principally with the adaptation of the existing standards of the *Pharmacopoeia* to the changed conditions of wartime, and with the preparation of monographs on new substances for which it is evident that pharmacopoeial standards are required. A Fourth Addendum to the *British Pharmacopoeia, 1932*, is in preparation. This will include amendments already made official by notices in the *Gazette*, new monographs prepared for the next volume but which it is now considered should be forthwith made official, and amendments relating to glycerin made in accordance with the recommendations of the Committee on Substitutes for Glycerin and Sugar. In this work the Commission has been in close association with the Therapeutic Requirements Committee of the Medical Research Council and the War Emergency Formulary Committee of the Ministry of Health, and certain of the amendments and new monographs are proposed for inclusion in the Addendum in order that materials required for the prescriptions of the War Emergency Formulary shall have proper official definitions.

Appointments

The Council nominated Mr. C. G. Lowry for appointment by the Minister of Home Affairs, Northern Ireland, as a member of the tribunal constituted under the Dangerous Drugs Regulations, 1938. This tribunal deals with cases in which it is suspected that a practitioner is supplying or prescribing drugs or preparations for himself or other person otherwise than is properly required for medical treatment. The tribunal consists of three medical practitioners with a legal assessor, one of the members to be appointed on the nomination of the Council, the others to be appointed by the Minister.

Under the Temporary Provisions Order whereby in the event of the office of a direct representative becoming vacant the Council itself may fill the vacancy, Dr. Thomas Fraser of Aberdeen, President of the British Medical Association, was elected a direct representative for Scotland to the seat recently vacated by the resignation of Sir Norman Walker.

Prof. Sydney Smith was appointed by the Council a member of the Dental Board.

The chairmen of the Education, Examination, and Public Health Committees—namely, Colonel H. L. Tidy, Dr. R. J. Brocklehurst, and Mr. John Ritchie respectively—were reappointed for 1941-2.

Prof. J. S. B. Stopford was re-elected chairman of Business.

DISCIPLINARY INQUIRIES

Conviction for giving False Information

The Council considered the case of ARTHUR JOHN IRELAND, registered as of Tunstall, Staffordshire, who was summoned on the charge that he was convicted at Chester Assizes in February last of the following misdemeanours: (1) of giving false information concerning a birth, contrary to Sect. 4 (1) (*a*) of the Perjury Act, 1911; (2) of making a false statement in a notice required to be made by a Public General Act of Parliament, contrary to Sect. 5 (*b*) of the Perjury Act, 1911; and was bound over in the sum of £25 to be of good behaviour for two years and to come up for judgment if called upon. Dr. Ireland was present, accompanied by Mr. George Bankes, counsel, instructed by William Gorringe and Co., solicitors.

Mr. Winterbotham, the Council's solicitor, said that these proceedings concerned the alleged birth of a son to Mrs. Ireland on May 13, 1939. Dr. Ireland at this time was not living with his wife, although he saw her at times; and she helped him in his practice by keeping his accounts. She had, however, some years after their formal parting, gone through a form of marriage with another man, and she was accustomed to describe herself as "Lady Haldon." Lord Haldon died in August, 1938, so that if she had a son born subsequently he would inherit the title. It was alleged at the trial that with the help of her secretary, Isabella Blackett, she arranged with a woman in the neighbourhood to take away a baby. "Lady Haldon" was sentenced to three years' penal servitude on the charge of making a false claim about the baby's birth and on two charges of bigamy. Dr. Ireland's part in the affair was to send to the registrar of births and deaths at Knutsford a letter dated March 17, 1939, stating: "I beg to inform you that Lady M. Haldon gave birth to a male child (living) on March 13 at 7 p.m." It was the duty of persons attending a confinement to send a statement to the medical officer of health, and the fact that the statement in this instance was sent to the registrar caused inquiries to be made. When inter-

viewed by a detective superintendent Dr. Ireland said: "I was present at the delivery; at least I delivered the afterbirth. I was the time at approximately 7 p.m.; I could not tell to a moment." In binding over Dr. Ireland, who was a captain in the R.A.M.C., Mr. Justice Croom-Johnson indicated that he might have dealt with the case by way of imprisonment, but he said: "I think the public interest will be best served by allowing you to go back and continue your duty. I have been struck by your military record." There was no evidence that Dr. Ireland was concerned in arranging for a baby to be brought to the house.

Mr. Bankes said that when in 1917 Dr. Ireland married this lady she described herself as 23 years of age, but evidence was called at the trial which showed that she was born in 1878, so that she would have been over 60 at the time of this alleged birth. He had apparently been told that she was going to have this baby; later he saw the baby, and he wrote the letter which formed the substance of the charge. He was unaware at the time that the lady was still legally his wife. He was completely deceived by this woman, and accepted her word that the baby was hers.

After deliberation *in camera* the Council found the conviction proved and instructed the Registrar to erase from the Register the name of Arthur John Ireland.*

Cases following Convictions at Courts-Martial

Several cases came before the Council on convictions from courts-martial. The first was that of JOHN ALEXANDER TOLMIE, registered as of Anlaby Road, Hull, who was charged that being a registered medical practitioner and a captain in the R.A.M.C. he had been guilty of infamous conduct in a professional respect in being found guilty at a general court-martial held at Reading on September 20 last of being drunk at Botley when on active service, and was sentenced to be dismissed from the Army.

Dr. Tolmie was present and was represented by Mr. A. A. Pereira, counsel, instructed by Messrs. Le Brasseur and Oakley, for the London and Counties Medical Protection Society.

The Council's solicitor handed in the certificate of the conviction, and said that Dr. Tolmie had been previously before the Council in 1922 on petty sessional convictions on two occasions of driving a motor-car or of being in charge of a car while under the influence of drink. Dr. Tolmie in evidence admitted the charge and expressed his great regret. Since his previous conviction until the Botley incident he had given no cause for complaint on the ground of insobriety. At the time of the incident he was worried about his private affairs and was induced by a friend to take more drink than was good for him.

The Council put Dr. Tolmie on probation for twelve months.

The next case was that of OLIVER WATSON, registered as of Caledon, Co. Tyrone, who had been found guilty by general court-martial held at Dunblane on September 11 1940, of having been drunk in the field when on active service on the previous March 24 and May 24. He had been sentenced to be dismissed from His Majesty's service.

Dr. Watson was represented by Mr. R. S. Carden, solicitor, who said that Dr. Watson denied having been drunk on these occasions. His Irish brogue might be mistaken for indistinctness of speech due to drink. He also complained that five or six months had elapsed between the occurrence which had led to the charge and the date of the court-martial. The occurrences took place in France before the Dunkirk evacuation and the court-martial in Scotland. If there was any substance in these charges he should have been dealt with on the spot. The interval seriously handicapped the defence in getting evidence. The tradition in the British Army that an officer should not say anything against an N.C.O. had also worked unfortunately against Dr. Watson in this instance.

In this case also the respondent was placed on probation for twelve months.

In two other cases in which a charge of drunkenness had led to a court-martial and dismissal from the Service there appeared to be some doubt as to whether notice had been served on the practitioners, and both were postponed to a later session.

Charge of Canvassing and Advertising

The case of HORATIO MATTHEWS, registered as of 30, Harley Street, London, came again before the Council. In May, 1940, the Council found that this respondent had canvassed and advertised for the purpose of obtaining patients and promoting his own professional advantage (*Supplement*, June 8, 1940, p. 90) and he was placed on probation for twelve months.

Dr. Matthews did not now appear before the Council, but a letter from him was read in which he said: "Six months' deliberation has confirmed my opinion that the G.M.C.'s action in publishing in the daily press that it had been proven against me that I advertised for eye patients was both unjust and illegal. As appeal against it is beyond my power I am now, after this letter reaches you, regarding myself as in your Council's judgment guilty of infamous conduct in a professional respect on this account. I shall accordingly hereafter conduct my calling as if removed from the *Medical Register* . . . In a later letter he wrote: "I will not recognize the proceedings of the Council of May last, and . . . I hold them to be both illegal and unjust. Therefore I shall not appear before the Council again."

The Council judged Horatio Matthews to have been guilty of infamous conduct in a professional respect and instructed the Registrar to erase his name.

Convictions for Drunkenness

A large number of the remaining cases arose out of police-court convictions of drunkenness or cognate offences. REUBEN DENNY, registered as care of a firm in Jermyn Street, S.W., against whom judgment had been postponed at a previous session after convictions for driving a car under the influence of drink and for being drunk and incapable had been proved, was called but did not appear. It was stated that he was serving in the Royal Navy, and the case was again postponed.

*This is the first case of false certification with which the Council has had to deal since the issue of the President's memorandum drawing attention to the necessity for extreme care in such certification.

E.M.S.: CLASS III PRACTITIONERS' FEES

THE following circular (No. 2394) has been sent by the Ministry of Health to county and county borough councils and other authorities with hospitals in the Emergency Medical Service and to voluntary hospitals in the scheme.

1. I am directed by the Minister of Health to refer to Circular 2176 dated October 19, 1940, which announced certain modifications in the terms of service of Class III officers of the Emergency Medical Service and in the method of payment for medical services remunerated on the accepted bed basis at voluntary hospitals, and to Circular 2329 dated April 19, 1941, which specified the conditions under which payments of one guinea were to be made for Service out-patients in accordance with paragraph 3 (*e*) of Circular 2176.

2. The following further arrangements have now been agreed, after consultation with the Advisory Emergency Medical Service Committee, and in so far as they modify existing practice will take effect, as regards paragraphs 3 and 4, as from March 1 last, and as regards paragraph 5 from June 1 next.

3. *Method of calculating sessional fees of Class III practitioners at hospitals at which the sessional method of payment is in operation.*

(*a*) In accordance with existing practice, short sessions of less than one hour each occurring in any week running from Saturday midnight to Saturday midnight are to be aggregated and the total hours so ascertained divided by two, the result being the number of sessions to be paid for. If the remainder is half an hour or more it is counted as a full session. If it is less than half an hour it will be disregarded, but if the total time worked in a week is less than half an hour it will be carried forward to the next week in which further service is given. Sessions lasting between one and two hours are counted as one session. Where a practitioner attends continuously for more than two hours, the same principles are applied to the excess over two hours. It is proposed to incorporate this system in the contracts of Class III officers.

(*b*) Where the sessional fee is, owing to distance from the practitioner's home or consulting-room, in excess of 2½ guineas or 1½ guineas as the case may be, the excess is payable for each session, however short. In other words, the principle of aggregation applies to the basic fees and not to the additional sums which represent an allowance for time and mileage. Thus, if a practitioner attends for twenty minutes on each of four occasions in one week at a distance for which the scale fee is £2 12s. 6d., plus 5s., he will be entitled in all to £2 12s. 6d., plus four times 5s.—total £3 12s. 6d.

(*c*) Where a Class III practitioner is specially summoned to attend a particular patient owing to some urgent condition and out of the normal course of his visits to the hospital, a basic fee of 1½ guineas for a specialist and 1 guinea for a general practitioner will be payable where the period of attendance at hospital is less than one hour. Where the period is between one and two hours the full fee of £2 12s. 6d. or £1 11s. 6d., as the case may

be, will be payable. If the period exceeds two hours, the same principles will be applied to the excess over two hours. Where, however the practitioner is so summoned at night—i.e., between 9 p.m. and 6 a.m.—payment at the full sessional rates will be made irrespective of the length of the period of attendances. Special calls to which this paragraph applies would not be included in the process of aggregation.

4 *Administrative Sessions.*

The arrangements referred to in paragraph 2 (3) of Circular 2176 normally apply only in the case of Class III officers attending hospitals where the sessional method of remuneration is in force. When in an occupied bed basis hospital a Class III consultant or specialist who does not normally visit the hospital is required by the hospital officer to undertake administrative work exceptionally, the appropriate sessional fee will be payable.

5 *Payments for second opinions or special investigations.*

As from June 1, 1941, the conditions for the payment of the fee of 1 guinea referred to in paragraph 3 (*e*) of Circular 2176 will be as follows:

(*a*) The fee will be payable where the medical officer sending the patient desires a second opinion or special investigation (or both) by a physician or surgeon or other medical officer in clinical charge of patients on the visiting specialist staff of the hospital, and submits a statement of the patient's condition or other relevant facts together with an indication of the matters on which he desires a consultant opinion or investigation. The specialist will be required to state his opinion on the result of the special investigation in writing, and a copy of the report must be retained by the hospital. Where the patient is referred for admission—if that should be considered advisable—the fee of £1 1s. 0d. will not be payable, but if he is referred for a second opinion and as a result of the examination by the specialist is admitted to the hospital, the fee of £1 1s. 0d. will be payable in the usual way.

(*b*) In certain hospitals it is the custom for the medical officer of a special department—e.g., a radiologist or pathologist—to make a special investigation and report within the scope of his specialty, without any examination of the patient by a specialist in clinical charge of patients as defined in (*a*) above. Where a medical officer sends a patient to one of these hospitals for an investigation of this kind the fee payable will be on a scale which is being drawn up in consultation with the Central Medical War Committee and not at the flat rate of 1 guinea. The scale will be communicated to you in due course. In other respects the conditions specified under (*a*) will apply.

(*c*) Not more than one fee of £1 1s. 0d. will be payable in respect of services to any one patient in connexion with the same disability. Where the services of more than one practitioner are involved, these will be covered by the fee, the apportionment of which will be a matter for the medical staff of the hospital to decide (see (*g*) below).

(*d*) Payments as set out above may also be made under the same conditions for references of civilian patients from other hospitals within the Emergency Hospital Scheme, and for Service patients, whether sick or injured, sent from another hospital. They may also be made in the case of recruits to the Women's Auxiliary Services in respect of whom the Service Department, after examination by members of medical boards, desires specialist advice before deciding whether the recruit is to be accepted.

(*e*) The fee will not be payable where the practitioner responsible for the second opinion or special investigation, or all the practitioners, if there are more than one, is or are in receipt of a full-time salary from the hospital.

(*f*) The patients in respect of whom fees are payable must be clearly identifiable in the hospital's registers, so that the particulars may be available for audit purposes where required.

(*g*) Subject to the above, the fees will be repaid to the hospital and the subsequent disposal of the moneys to individual members of the hospital staff will depend upon the scheme approved by the medical staff. These special fees should be shown at the foot of the monthly statement of out-patient attendances and included in the total in the periodical claim from the hospital on Form A.G.136.

(*h*) Where Service or other patients are sent to out-patient departments for treatment and not under the foregoing procedure, the normal capitation fees will be payable—i.e., 1s. 6d. (with the guaranteed minimum of 1 guinea) if the patient is admitted and 6d. if it is decided to give out-patient treatment.

The Home Office announces that Drs. Henry Scott Buckland and Clifford Gordon-Wilson are once more authorized persons for the purposes of the Dangerous Drugs Act, 1920.

Correspondence

Bedside Manners

SIR,—Dr. S. F. Marwood in his paper, "Free Choice of Doctor" (*Supplement*, May 17, p. 66), advocates teaching students the art of "handling people" or "bedside manner," although he does not like this term. I suggest that the student might be advised to peruse the following extract from Burton:

"'Tis an ordinary thing with us to account honest, devout, orthodox, divine, religious, plain-dealing men idiots, asses, that cannot or will not lie and dissemble, shift, flatter, adapt themselves to the station in which they were born, make good bargains, supplant, thrive, fawn upon their patrons, learn the usual methods of getting on, be scrupulous in the observance of laws, manners, customs, praise in glowing terms, defend with vigour, adopt others' opinions, doubt nothing, believe everything, endure everything, resent nothing, and do all the other things which lead to promotion and safe position, which make a man fortunate beyond all question, and truly wise, according to our notions; that cannot temporize as other men do, hand and take bribes, etc., but fear God, and make a conscience of their doings. But the Holy Ghost, that knows better how to judge, He calls them fools."—*The Anatomy of Melancholy*, vol. I.

Dr. Johnson said of Fitzherbert, in whom he considered that there was no sparkle and no brilliancy: "He was an instance of the truth of the observation that a man will please more upon the whole by negative qualities than by positive; by never offending than by giving a great deal of delight. In the first place, men hate more steadily than they love; and if I have said something to hurt a man once, I shall not get the better of this by saying many things to please him."

The young doctor may find a brusque manner an expensive luxury, but an invariable courtesy so readily extends itself to obsequiousness, and then favours exploitation and oppression of the profession of which we now have sufficient.—I am, etc.,

Gloucester, May 17. C. DE W. GIBB.

Postgraduate News

The Fellowship of Medicine announces the following courses for Final F.R.C.S. candidates: (1) Clinical demonstrations, 2 p.m., Wednesdays, July 2 to 23; (2) Revision course, daily 10 a.m., July 7 to August 1; (3) Practical operative surgery, Mondays, Thursdays, and Fridays, 2 p.m., July 7 to August 1; (4) Urology course, Thursdays, 2.30 p.m., August 7 to 28.

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—*Brompton Hospital*, S.W.—Mon. and Thurs., 5 p.m., M.R.C.P. course in Chest Diseases. *West End Hospital for Nervous Diseases.*—Tues. and Fri., 3.30 p.m., M.R.C.P. course in Neurology. *Royal Chest Hospital*, City Road, E.C.—Wed., 3.30 p.m., M.R.C.P. course in Heart Diseases.

EDINBURGH POSTGRADUATE LECTURES.—At Edinburgh Royal Infirmary, Thurs., 4.30 p.m. Prof. Sydney Smith: Wounds from Firearms.

Section of [illegible].—Wed., 4.30 p.m. Dr. A. P. Cawadias.
General Meeting.—Fri., 5 p.m. Candidates for Fellowship.
Section of [illegible].—Annual general meeting. Discussion: Factors which make for Safety in the Pre-operative and Post-operative Treatment of Carcinoma of the Rectum.
Sections of Laryngology and Otology.—Fri. Combined summer meeting at Horton Hospital, 10 a.m., 11.30 a.m., Discussion: Relationship of to Thoracic Surgery, 2.15 p.m., Mr. V. E. [illegible] Ear, Nose, and Throat Department in the E.M.S.

APPOINTMENTS

MCINTYRE, D. M., M.B., Ch.B., Examining Factory Surgeon for the Scalbergh District (Yorkshire, West Riding).

B.M.A.: Branch and Division Meetings to be Held

BATH, BRISTOL, AND SOMERSET BRANCH: BRISTOL DIVISION.—At Physics Lecture Theatre, Royal Fort, University of Bristol, Thursday, June 12, 3.30 p.m. Symposium: "Experiences of First Aid in Air Raids." Opener, Dr. H. M. Golding; other speakers, Prof. R. H. Parry, Dr. I. G. Davies, Dr. A. M. Fraser, Dr. M. E. J. Packer, Dr. J. Morton Evans, junior, Dr. W. Woolley, Dr. W. H. Hayes, Dr. H. D. Pyke, and Dr. R. J. Stephen. All medical practitioners are welcome to attend the meeting.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

BIRTH

ROBINSON.—On May 13, at Denison Hall, Leeds, to Joy (née Portlock), wife of Lieut. G. B. Robinson, R.A.M.C., of Woodside, Knaresborough, a son.

'HYPOLOID' BRAND SULPHANILAMIDE L.S.F.

A solution for parenteral administration

The activity of soluble sulphanilamide derivatives is proportional to the amount of sulphanilamide actually present. Each 20 c.c. of 'Hypoloid' Solution of Sulphanilamide L.S.F. provides 3 grammes of Sulphanilamide as sulphanilamide lactoside sodium formaldehyde-sulphoxylate. Practically the whole of the sulphanilamide becomes readily effective.

Apart from the relatively high sulphanilamide content 'Hypoloid' Sulphanilamide L.S.F. has the added advantage of presenting a nearly neutral solution.

'Hypoloid' Sulphanilamide L.S.F. is available as a sterile solution in 'Hypoloid' Ampoules of 5 c.c. in boxes of 6; also in single ampoules of 20 c.c.

Also available:

'TABLOID' BRAND SULPHONAMIDE–P (SULPHANILAMIDE)

A compressed product for economical oral administration. 0·5 gramme products in bottles containing 25 and 100.

'WELLCOME' BRAND SULPHONAMIDE–P (SULPHANILAMIDE)

A crystalline powder in bottles containing 25 and 100 grammes.

Allantoin—a new Therapeutic Agent

Allantoin is a cell-proliferant, found in the embryonic fluids and also in the growing parts of many plants. Chemically pure synthetic Allantoin has been increasingly used by surgeons, especially in the United States, as a stimulant of cell-proliferation. It has proved particularly useful after skin-grafting, and in the treatment of varicose and other sluggish ulcers, bed-sores, and slow-healing wounds.

Whilst promoting cell mitosis, Allantoin in no way retards or interferes with amoeboid cell-movement.

Allantoin is non-toxic and non-irritant.

Mode of Application

Allantoin may be used as a powder, or in aqueous solution by means of gauze packs steeped in the liquid. Alternatively, the 2% ointment may be applied to the lesion; in the case of deep wounds, gauze impregnated with the ointment may be packed into the cavities. Sulphanilamide with Allantoin should be employed in cases of gross infection.

Preparations

The following forms are now available: pure substance; sterile solution in n. saline; 2% ointment in special 'Fissan' base; 2% ointment with 5% or 10% sulphanilamide for cases of infection; also Allantoin powder 4% with sulphanilamide 96%. The medical profession is invited to send for literature and further information to the manufacturers: Genatosan Ltd., Loughborough.

THE BACTERIOLOGICAL INVESTIGATION OF WOUNDS TREATED BY THE CLOSED-PLASTER METHOD

BY

JEAN ORR-EWING, B.M. J. C. SCOTT, M.S., F.R.C.S.

AND

A. D. GARDNER, D.M., F.R.C.S.

Although the last war left us with a good general knowledge of the bacterial flora of open wounds, the present increasing use of the closed-plaster method of treatment calls for more information about the special characters and changes of the flora under these peculiar conditions; and it is this type of information that we have aimed at obtaining.

At the outset it was clear enough that completely covered wounds cannot be adequately investigated without devising some means of bacteriological access to the wound as often as desired; and our investigation therefore began with the invention of a transparent window, easy to open and to close again hermetically, which could be incorporated in the plaster casing of any limb. In this we had the advice and collaboration of Prof. Seddon and Messrs. Corry, Foley, and Elliot Smith. One of the results of the work has been the development of a type of window more satisfactory than the first one, which was found to have a bad effect on the surface of the wound directly under it; and we hope that our experience may be of use to other workers in this field.

At the outset we expected a large number of air-raid casualties to be available, but it has been our happy misfortune to have instead only a slow trickle of compound fractures and lacerations such as occur at all times in civil life, with one or two aerial wounds from the surrounding district. Nevertheless, frequent examinations of a few wounds have given some information not available by rarer examinations of many. Up to the present we have made 73 complete analyses from the flora of 10 cases (often with two wounds), first at excision whenever possible, and then at short intervals after the application of the plaster. In the later stages examinations were made at plaster changes and usually, at less frequent intervals, between changes. Windows were not fitted to patients who were up and about.

The subjects investigated all had injuries to the limbs received in road, aeroplane, or machinery accidents (8) or shell-splinter and gunshot wounds (2). All but one had compound fractures. Five of the cases followed from the beginning were operated upon within eight hours of the accident, two at sixteen hours, one at forty-eight hours. Clinical notes are given towards the end of the paper.

Methods

Access to the Wound.—Various types of window have been tried. The ideal opening should fulfil the following conditions: (1) it must not admit extraneous bacteria to the wound either at the time of opening or at intermediate periods; (2) it must allow representative specimens of the wound flora to be obtained; (3) it must not interfere in any way with the treatment of the wound. To fulfil this last condition it was found by experience that free drainage must be allowed and that an even pressure on the tissues must be maintained: for example, if the under surface of

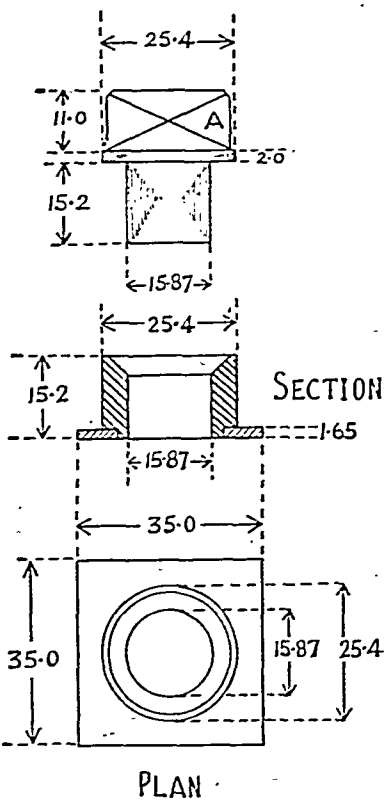

Diagram of apparatus giving access to the wound surface (measurements in millimetres)

the apparatus is not flush with that of the plaster, oedema occurs in the part of the wound immediately beneath the window. The most satisfactory apparatus so far devised (see diagram) consists of a small cylinder (internal diameter 1.5 cm., height 1.5 cm.) mounted on a square plate cm.) bored with a central hole (diameter 1.5 piston fits closely into the cylinder; its upp

so as to cover the cylinder rim, and a rectangular handle is attached. The whole apparatus, which is made by Mr. S. W. Bush of the School of Pathology, Oxford, consists of "perspex," the parts being cemented together with "perspex" cement. (No doubt other plastic material could be used.) The apparatus is sterilized by immersion in 10% formalin, washed in saline, and applied directly over a portion of the wound. Underlying gauze packing is, if necessary, split just beneath the cylinder in order to give access to the tissues. Plaster is then applied as usual, the cylinder being surrounded but not covered. Samples are obtained by momentary removal of the piston and insertion of a swab. We have always scrubbed up and used sterile gloves, masks, and overalls while taking samples. These samples have proved to be representative of the flora, provided that (1) direct access is obtained to the wound surface; (2) the apparatus lies over the most dependent part of the wound. In all respects the apparatus has proved quite satisfactory.

Bacteriological Methods

Direct microscopical observation of the discharge was made at every examination, and was used both as a check of the cultural methods and as a basis for a rough estimate of the absolute and relative richness of the flora.

Cultivation.—In general the methods of isolation recommended in the Medical Research Council War Memorandum No. 2 have been followed: plating on blood agar incubated aerobically and anaerobically, and cultivation in Robinson's cooked meat medium and in litmus milk. We have, however, modified and extended the methods recommended for the detection and isolation of organisms in the presence of *Proteus*. Samples are plated on two horse-blood agar plates containing 0.04% potassium tellurite and on one nutrient agar plate containing crystal violet (1/50,000). One tellurite plate is incubated anaerobically. On this plate haemolytic streptococci and *Staph. aureus* have been found to develop satisfactorily, usually within twenty-four hours. *Proteus* is either completely inhibited or grows in discrete colonies. This is the lowest concentration of tellurite which we have found to prevent spreading growth with certainty. On one or two occasions it has been necessary to replate the picked coccal colonies on further tellurite medium, but the separation from *Proteus* has nearly always been complete at the first pick. Colonies of *Str. pyogenes* after twenty-four hours' anaerobic incubation are small, black, and haemolytic; hence they are readily defected and picked off. In preparing the medium care should be taken to bring all the ingredients to a temperature of about 45° C. before mixing and pouring. Spontaneous haemolysis often takes place in medium mixed at a higher temperature.

Diphtheroids, as is well known, develop, often in pure culture, on the aerobic tellurite plate. Some strains of *Staph. aureus* and very occasionally other micrococci may also appear, but we have usually been unable to isolate the non-pathogenic micrococci in the presence of *Proteus*. This organism is completely inhibited on the crystal-violet plate, on which *Ps. pyocyanea* grows well, as do some members of the genus *Bacterium*.

Findings

Presence of Pathogenic Organisms.—Toxigenic *Cl. welchii* (Type A toxin) was present in one case (No. III). It was first isolated at the fourth examination, which was made a few days after the first change of plaster. It was re-isolated on two occasions during the succeeding month. Four weeks later it had disappeared, and was not found again. The patient never at any time showed any clinical evidence of gas gangrene.

Haemolytic streptococci belonging to Group A and *Staph. aureus* were each found in seven cases; five of these patients harboured both cocci. Both these microbes have invariably persisted in the wound from the time they were first observed to the end of the plaster treatment—in one case for a period of nearly seven months. Dr. F. Griffith kindly typed the streptococcal strains on repeated occasions. All but one belonged to well-recognized types of Group A. The remaining strain, which persisted in the wound for six and a half months, reacted to a group serum, F 69. The type originally isolated persisted in each case throughout the period of observation. One Group B strain was isolated from Case X. It disappeared within a few days, and evidently had no pathological significance. It is of some interest that it was detected in the wound within three hours of injury.

Saprophytic Organisms.—A complete list of the organisms isolated in each case, with the period during which they were observed and an estimate of the approximate duration of the infection, is given in Tables I (persistent microbes) and II (microbes tending to disappear from the wound).

TABLE I.—*Organisms isolated from Wounds. Pathogens and Persistent Organisms*

Organism	Case and Period of Observation[1]	No. of Cases	Approximate Duration
Str. pyogenes, Group A[2]	I (19–240), III (8–86), IV (90–115), V (95–117), VII (1–81), VIII (1–51), X (4–65)	7	Indefinite
Str. pyogenes, Group B	X (1–8)	1	< 16 days
	I (3–172), V (1–117), VI (50–89), VII (1–81), IX (18–31), X (1–65)	7	Indefinite
Staph. aureus	I (1–51), III (26–46), II (7–84), III (8–207), IV (50–100)	1	4–6 weeks
		3	Indefinite
Cl. welchii		1	Indefinite
Proteus	V (1–117), VI (50–89), VII (11–81), VIII (23–51), X (4–65)	4	Variable; few weeks; indefinite
Diphtheroid Type I ..	I (70–205), II (15–28), III (8–207), VIII (11–33)	4	Variable; few weeks; indefinite
Ps. pyocyanea		1	Indefinite

[1] Roman numerals are case numbers. In brackets are the periods of observation in days; day 1 being the day of the excision operation.
[2] Types of streptococcus: Case I, Type F 69; Case III, Type 12; Case IV, Type 11; Case V, Type 11; Case VII, Type 11; Case VIII, Type 27; Case X, Type 12.

TABLE II.—*Non-persistent Organisms*

Organism	Cases	No. of Cases	Duration
Str. viridans	VI	1	< 7 days
Staph. albus	I, III, VI, VII, VIII	5	< 7 days
Micrococcus	I, III, V, VI, VII, VIII	6	< 3 weeks
Diphtheroids other than Diphtheroid Type I	I, III, V, VI, X	5	< 7 days
Bacterium	I, II, V, VIII	4	1–6 weeks
Chromobacterium	II	1	< 7 days
Ps. fluorescens	I, II, III, V, VII, VIII, IX, X	1	< 7 days
Bacillus	II	8	1–4 weeks
Cl. sporogenes	II	1	< 3 weeks
Cl. bifermentans	I, II	1	< 3 weeks
Plectridia (various)		2	Variable

Since wholly harmless microbes usually disappear within a few days or weeks, it is curious to note the persistence of the diphtheroid "Type I." This is in marked contrast with all the other diphtheroid types, which disappear within a few days. This organism ferments glucose, saccharose, and galactose, but not maltose, lactose, or mannitol. It appears to conform to the Type I of the M.R.C. Committee's list of unclassified corynebacteria (Andrewes and others, 1923). In general, the flora of these plaster-treated wounds does not appear to differ materially from that of open ones of similar type which receive early treatment. The incidence of anaerobic infections (from both sporing and non-sporing organisms) is low in comparison with battle casualties in 1914-18 and in 1940. Anaerobes are not, however, commonly found in air-raid casualties, and such wounds, which receive comparatively prompt treatment, appear to have a flora similar to that observed in our series (Douglas, Fleming, and Colebrook, 1920; Miles and others, 1940).

Time of Introduction of Organisms

"*Hospital Infections.*"—We are satisfied that in normal circumstances no infection of the wound takes place through

the plaster casing. Infection has, however, been shown to occur fairly often during plaster applications. Evidence for these statements is based upon observations made on wounds fitted with windows so that the nature of the flora can be repeatedly observed both before and after the change of plaster. Thus, at the first examination made after changing plaster, species new to the wound were detected in 7 out of 12 samples—11 new species being found. On the other hand, 21 samples taken at subsequent examinations before the next plaster change showed no new species. Of our 10 patients, 4 were proved to have been infected in this way. A fifth also acquired new species during a period when he had no window, and the source of infection could not be tested. The bacteria so acquired are listed in Table III. These observations apply only to examinations

TABLE III.—*New Species appearing after First 15 Days of Treatment*

Organism	Case	Plaster No.	Fate of Organism
A. In Patients fitted with "Window" in Plaster			
Str. pyogenes (Group A)	I	2	Persisted > 7 months
Cl. welchii	III	2	Disappeared < 63 days
Str. viridans	VI	2	" < 19 "
Staph. albus	VI	2	" < 21 "
Micrococci (1)	VI	2	" < 21 "
" (2)	VI	2	Persisted > 40 "
Bacterium	I	2	Disappeared < 50 "
Ps. pyocyanea	I	3	Persisted > 133 "
Plectridium	II	2	" > 63 "
Bacillus	III	3	Disappeared < 57 "
	VI	2	" < 39 "
B. In Patients without "Window" in Plaster			
Diphtheroids	V	3 (?)	Disappeared < 39 days
Str. pyogenes	V	Uncertain	Persisted
Str. viridans	V	"	Disappeared < 48 days

made after the fifteenth day following the accident. During the first fortnight new species appear in the wound, often in considerable numbers. For reasons given below we believe these to have been introduced before or during the first plaster application.

Pre-hospital Infection.—Our observations throw no light at all upon the sources of pre-hospital infection—i.e., whether this is acquired at the time of the accident or by first-aid treatment, etc., as suggested by Hare (1940). We are, however, inclined to think that the majority of infecting organisms in our series were introduced during this period in spite of the fact that they were often not detected in the wound for seven or even occasionally for fifteen days after admission. In other words, there appears to be a very considerable lag in development of many species in wounds which have been thoroughly excised and cleansed within a few hours of the accident. Some species appear to have been permanently removed by this procedure: thus 12 strains of various organisms isolated from the tissues removed at operation never reappeared at subsequent examinations. These were *Proteus* (Case V); *Staph. albus* and other micrococci (Cases I and III, four species; Case V, one species; Case X, three species); diphtheroids (Cases I and III); *Ps. fluorescens* (Case II).

The progressive development of new species during the first fifteen days is shown in Table IV (cases treated within eight hours of the accident) and Table V (cases treated sixteen to forty-eight hours after the accident).

Most of the delayed development takes place in the group treated early. The appearance of new species on the third or fourth day is to be expected in this group, for many species of organisms introduced at the time of injury are likely to be present in numbers too small to be detected at the first examination, carried out only two or three hours later. It will be seen, however, that six species appeared between the third and seventh or eighth days, one between the fourth and tenth, and four between the seventh and fifteenth days—a total of eleven species. (Technical difficulties unfortunately prevented specimens from being

obtained from all patients during this period.) Although it is possible that these microbes may have been introduced during the process of opening the window, it seems more probable that they were in fact present but undetected at previous examinations. For, on the first assumption, we should have introduced eleven new species in the course of eleven examinations made between the third and tenth days, while no new species has been detected as a result of twenty-one similar examinations made at later periods. The point needs further investigation, for any delay in

bacterial development at this time, when the barrier of granulation tissue is being built up, may be of great benefit to the patient.

Our reasons for thinking that most (though doubtless not all) of the flora is introduced before and not during débridement are that (1) the number of new species is far greater in the early than in the comparatively late cases, and (2) such infection is by comparison rare at subsequent plaster changes.

Pseudomonas pyocyanea

We have paid some special attention to this organism since the suggestion has recently been revived that it may have a beneficial effect upon wounds and, in particular, that it may inhibit the growth of *Str. pyogenes* and *Staph. aureus* (Trueta, 1939). It has been present in four of our cases (I, II, III, VIII), and three of these have persistently harboured haemolytic streptococci in large numbers; two patients had in addition a *Staph. aureus* infection. The evidence does not suggest that the growth of any other organism is influenced by the presence of *Ps. pyocyanea*.

This question is complicated by the existence of many different strains of the species, which differ in colony form, pigment production, and autolytic action. Only one of our strains (Case III) was highly coloured and strongly autolytic. This strain was not associated with a coccal infection. Very large numbers of observations would be required to show whether this was or was not a purely chance connexion.

The following are the clinical notes of the present series of cases.

Case I

Persistent microbes: *Staph. aureus, Str. pyogenes* (from day 19), diphtheroid Type I, *Plectridium, Ps. pyocyanea* (from day 70).

27/6/40.—A man aged 45 sustained compound fracture of right leg in motor-cycle accident. Admitted to W.M.O.H. 11 a.m. General condition satisfactory; grossly compound fracture, junction of middle and lower thirds of right tibia and fibula. 11.15 a.m., operation: Wound 3 in. × 2 in. on anterior medial aspect; deep wound 2 in. × 1 in. antero-lateral aspect; skin cleaned with soap and water, antiseptic applied to margins of wounds; wound excised, and enlarged to allow removal of extremely lacerated underlying muscle; wound dressed with dry gauze; fracture reduced by manipulation; plaster applied.

8/7/40.—Patient has had a mild serum reaction, with slight rise in temperature. Leg is satisfactory. Plaster changed; wounds show healthy granulations. Slight discharge.

12/7/40.—Temperature elevated. Patient has pain over indurated area in perineum. This area gradually subsided without incision. Patient continued to run a mild evening temperature, up to 100°. Leg satisfactory.

30/7/40.—Plaster changed. Both wounds smaller in size, full of healthy granulation tissue. Fresh plaster applied. Two days following change of plaster patient had temperature up to 102° and general malaise.

2/8/40.—Temperature normal. No complaints.

29/8/40.—Plaster removed. Wounds healing well. Moderate discharge. No local inflammation. Again, following this change of plaster, patient had brief period of temperature up to 102°, which rapidly subsided.

5/9/40.—Patient allowed up, with crutches.

16/12/40.—Plaster removed. Clinically, union sound; both wounds almost completely healed. Radiographs show small sequestrum, which was removed.

16/1/41.—Wound healed. Union firm. Patient up with crutches, bearing weight.

Case II

Main persistent bacteria: *Proteus*; two clostridia ? non-pathogenic; diphtheroid Type I; also, intermittently, haemolytic streptococcus (seen four times but never isolated), and *Ps. pyocyanea*.

Man aged 21, injured in bomber crash. Compound fracture of lower third of tibia; also compression fracture of fourth cervical vertebra (discovered later) and minor injuries.

20/7/40.—Operation 2½ hours after accident. Cleansing and débridement of leg wound 6 in. × 3 in. in size, exposing 5 in. of tibia; full of dirt. Suture of upper third; plaster, with window. Sulphapyridine, 1 gramme i.m. 4-hourly.

21 and 22/7/40.—No significant rise of temperature. Sulphapyridine continued by mouth (0.5 gramme 4-hourly on 22nd), then discontinued.

29/7/40.—Steady improvement without fever. Plaster smelly.

9/8/40.—Plaster changed; good progress in healing.

28/8/40.—" Zimmer distraction " under spinal anaesthesia. Good position of bone achieved (plaster presumably renewed). No subsequent fever.

28/9/40.—Progress has been smooth; pins removed (plaster presumably renewed).

6/10/40.—Plaster removed. Wound healing well.

8/10/40.—Clinical evidence of bony union. Radiological report: " No sound union; some osteitis."

15/10/40.—Transferred.

Case III

Persistent microbes: *Str. pyogenes, Proteus, Ps. pyocyanea.*

At about 6 p.m. on August 23, 1940, a man aged 24 was involved in a motor-cycle accident and sustained injuries to the right leg. He was admitted to Radcliffe Infirmary and found to be suffering from compound fracture of right patella, compound supracondylar fracture of right femur into knee-joint, and extensive laceration of skin and muscles of lower part of thigh. There were no other injuries.

Operation was carried out at 8.45 p.m. under general anaesthesia. The skin was scrubbed with soap and water and shaved. The edges and all devitalized tissue were then excised, including the patella, which was in many small fragments and impregnated with road dirt. The cavities created by this thorough excision of the wound were lightly filled with dry gauze and the limb was encased in a plaster spica.

For about forty-eight hours the patient's condition was very good. He had little pain in the limb and no pyrexia. Then his temperature shot up to 104° and he began to complain of pain around the knee. He was immediately put on sulphapyridine and given 16,000 units of anti-gas-gangrene serum intravenously. A small window was cut in the plaster above the wounds so that the condition of the leg could be seen. There was more than an inch between the skin and the plaster, but no suggestion of gas in the tissues. The temperature settled a bit, but continued to swing up to 101° in the evenings. The plaster was removed on September 9 and a large pocket of pus was found tracking well up on the posterior aspect of the thigh. The large abscess was drained by a postero-lateral incision into its most dependent part.

Since that time the problem has been entirely one of drainage. The patient has had repeated changes of plaster and three operations for removal of sequestra and for drainage. Since the first three weeks his general condition has never given rise to any anxiety. At the time of writing his wounds are reduced to two sinuses, which are healing. The union of the fracture is unsound because of the removal of a large sequestrum.

Case IV

Persistent microbes: *Str. pyogenes, Proteus.*

17/5/40.—A man aged 34 sustained a technically compound fracture of the right femur following a bomb explosion. Was operated on at Bruges three hours later. Wound was sutured without exploration and plaster spica applied.

29/5/40.—Admitted to Pembury Hospital. Skeletal traction with Kirschner wire through lower end of femur on Thomas splint.

8/6/40.—Plaster spica applied.

10/6/40.—Admitted to W.M.O.H. Ill man; high temperature. Toes swollen.

17/6/40.—Plaster removed under general anaesthetic. Original wound opened. Large abscess evacuated. Sequestrum removed. Counter-drainage effected. Thomas splint, with strong traction, applied.

27/6/40.—Drainage improved. Plaster applied.

5/8/40.—Plaster changed under general anaesthetic. Wound healing. General condition satisfactory.

5/9/40.—Plaster removed. Pin inserted through tibial tubercle. Traction and Thomas splint to correct slight overlap.

9/9/40.—Position satisfactory. Plaster spica applied.

7/11/40.—Plaster changed. Wound clean; healing.

20/12/40.—Dressings changed. Two sequestra removed.

10/1/41.—General and local condition satisfactory.

NOTE.—This has been a problem of drainage from the beginning; each rise in temperature and deterioration in general condition has been associated with retention of pus, and has improved following the institution of adequate drainage.

Case V

Persistent microbes: *Staph. aureus*, *Str. pyogenes* (from day 95), diphtheroid Type I.

11/9/40.—9 a.m.: This patient, a youth aged 16, caught his arm in a machine, and was lifted up by the limb. Admitted to High Wycombe Hospital, and found to have compound dislocation of left elbow and compound fracture of both bones of forearm. 1 p.m.: Dislocation reduced under general anaesthetic; excision of wound; vaselined gauze, dressing, and plaster applied. 5 p.m.: Admitted to W.M.O.H. On examination, mild shock. Plaster splint; wound 4 in. long inner medial side of lower end of humerus. Apparently little loss of skin, but wide separation of edges. First dressing and bivalved plaster applied.

13/9/40.—General condition satisfactory. Plaster removed under general anaesthetic. Wound cleaned. Small wound on ventral surface of forearm opened. Some necrotic muscle excised. Dry dressing applied to both wounds. Fresh plaster.

1/10/40.—Discharged home in plaster.

24/10/40.—Plaster removed. Both wounds healing well, and filled with clean granulation tissue. Moderate discharge. Radiograph shows good alignment and early union of forearm fracture. Loss of joint space. Apparently beginning destruction of elbow-joint.

21/11/40.—Plaster changed. Condition as above, with further progress of healing.

17/12/40.—Patient readmitted with fever and some pain in the arm. History: On 3/12/40, while in quarantine for scarlet fever, he had a sore throat and pyrexia, and complained of pain in the elbow. Plaster was split and the wound inspected. He was given sulphanilamide for three days, and condition subsided. On 15/12/40 he again complained of pain, and had a rise of temperature.

On admission the temperature was 104°, with some swelling of the hand; no other signs with regard to the arm. The throat was inflamed and the right tonsil large and oedematous. Plaster changed; wounds healthy; no increase in discharge; no retention of pus. Fresh plaster applied.

19/12/40.—Temperature normal. No complaints. The administration of sulphanilamide was discontinued.

15/1/41.—Seen as out-patient. Has been free from pain and pyrexia since discharged from hospital. Plaster off. Wound of forearm healed. Good progress of healing of elbow wound. Radiographs show firm union of forearm fracture. Increase in destruction of elbow-joint. Plaster reapplied.

5/3/41.—No complaints. Plaster removed. Elbow wound healed except for small sinus. Little discharge.

Case VI

Persistent microbe: *Staph. aureus*.

16/8/40.—5 p.m.: Patient, a man aged 40, had left leg injured as result of enemy action. Admitted to Radcliffe Infirmary. Found to be suffering from very extensive lacerations of calf of left leg, from popliteal space to lower part of tendo Achillis. Large area of skin and underlying muscle shot away. 9 p.m., operation: Skin cleansed with soap and water; antiseptic applied to margins of wound; normal excision of wound, which involved excision of greater part of gastrocnemius, leaving soleus fascia exposed; following excision, dry gauze applied to wound and plaster to mid-thigh. Patient had no rise in temperature, with exception of 100.2° on 17/8/40, and made no complaint of his leg. Plaster was left untouched for seven weeks.

5/10/40.—Plaster removed. Some pus inside plaster; the gauze was removed with difficulty from wound, owing to granulations having grown into it. Wound was clean, granulating well. Fresh plaster was applied. Following this change of plaster there was no rise in temperature and no pain in the leg. Skin graft applied.

25/11/40.—A section of full-thickness skin 3 in. × 1 in. was taken from posterior aspect of left thigh. This wound was sutured, and the piece of skin removed was cut into a large number of small pieces and applied to the granulating surface. Vaselined gauze dressing applied.

18/12/40.—Whole area covered with thin layer of skin.

Case VII

Persistent microbes: *Staph. aureus*, *Str. pyogenes*, diphtheroid Type I.

20/10/40.—Motor-cycle accident, 10.30 p.m., to schoolmaster aged 21. Admitted to Wantage Hospital. Injuries to face, right hand, and right leg. Sterile dressings applied to wound. Laceration of face sutured.

21/10/40.—Admitted to W.M.O.H. General condition satisfactory. Marked contusions of right hand without fracture. Abrasions on dorsum. Oblique compound fracture right tibia and fibula, junction of middle and lower thirds, with wide separation. 3 p.m., operation: Wound 2½ in. × 1¼ in on postero-medial aspect of leg, with muscle protruding; skin carefully cleaned with soap and water, and margins of wound painted with antiseptic; wound enlarged to permit exploration of surrounding muscle; all dead muscle excised; wound dressed with dry gauze, fracture reduced by manipulation, and plaster applied with a perspex window over wound.

25/10/40.—No complaints re leg. Some cough and physical signs in left chest. Temperature 100°. Given sulphapyridine; 2 grammes initial dose, then 1 gramme four-hourly.

30/10/40.—Condition satisfactory. Slight rash over arms and trunk. Sulphapyridine discontinued.

15/11/40.—General condition good. Temperature within normal limits for past fifteen days. Plaster changed under general anaesthetic. Wound clean and granulating well.

18/11/40.—Patient allowed up with crutches.

24/11/40.—Patient had two days' fever, general aches and pains. Diagnosed influenza. Temperature again normal, no complaints.

13/12/40.—Plaster changed. Wound clean, granulating well. Slight excoriation of skin. Radiograph shows some callus formation.

21/12/40.—Discharged from hospital.

6/2/41.—Plaster changed. Wound almost healed. Clinically, fracture has united in satisfactory position. Radiograph shows good callus. Short plaster applied.

Case VIII

Persistent microbes: *Staph. aureus*, *Str. pyogenes*, diphtheroid Type I, *Ps. pyocyanea*.

20/10/40.—Motor-cycle accident to man aged 26. Admitted to Cottage Hospital with injuries to left hand and right knee. Sterile dressings applied to wound.

21/10/40.—Admitted to W.M.O.H. General condition satisfactory. Multiple abrasions dorsum of left hand. Large open wound right knee, with fracture lateral margin of patella. 3 p.m., operation: Wound about 4 in. × 3 in., ragged, with considerable loss of skin, skin of leg and thigh cleansed with soap and water; margins of wound painted with antiseptic; wound excised, including damaged muscle and fragment of patella; following excision of wound, knee-joint was closed with interrupted catgut sutures; wound dressed with dry gauze, and rubber drain inserted through stab wound to effect dependent drainage.

22/10/40.—Following the operation, the plaster was applied from high up in the groin to the ankle. Sulphapyridine, 2 grammes initial dose, 1 gramme four-hourly, was started. No complaints. Temperature 100.8°.

25/10/40.—Temperature normal. No complaints. Sulphapyridine discontinued.

14/11/40.—Plaster removed. Wound clean, granulating well. No infection in knee-joint. Fresh dry dressing and plaster applied.

22/11/40.—Since last change of plaster, patient has made no complaint. Temperature has been normal. Plaster changed. Wound healing well.

17/12/40.—Plaster bivalved. Local dressing of sulphanilamide powder applied.

20/12/40.—Secondary suture of wound. Following plastic operation and suture, moderate rise of temperature for four days, which settled down when a haematoma was evacuated from lateral side.

25/12/40.—Temperature normal. No complaints.

11/1/41.—Wound healed. Patient walking well.

Case IX

Persistent microbes: *Staph. aureus*, diphtheroid Type I.

14/11/40.—A man aged 45 had his right leg injured in a motor-cycle accident. Admitted to W.M.O.H. 5 p.m. with compound fracture of right tibia and fibula at junction of middle and lower thirds. At 5.30 p.m., under general anaesthesia, the wound was exposed. It was found to be a puncture about 2½ in. × 1 in. The skin was cleansed in the usual manner and the wound edges excised; all underlying muscle was viable, and only a small quantity of subcutaneous tissue was excised. Dry dressing; fracture reduced by manipulation; plaster applied.

16/12/40.—Since the operation the general and local condition of the patient has been satisfactory. No pain in leg and no pyrexia. Plaster changed; wound almost healed; little evidence of union of fracture. Fresh plaster applied.

4/1/41.—No complaints. Up on crutches without weight-bearing.

5/2/41.—Plaster changed; very small area not covered by skin. Union progressing; plaster applied below knee.

Case X

Persistent microbes: *Staph. aureus, Str. pyogenes,* diphtheroid Type I.

20/1/41.—At 7.45 p.m. patient, a man aged 61, was knocked down by a bus. Admitted to W.M.O.H. at 8.5 p.m. Found to have compound fracture of upper third left tibia and fibula, with extensive violence to the skin, and a large wound in the popliteal space. No loss of skin on posterior aspect. Medial dislocation of left ankle. General condition satisfactory. 9.50 p.m., operation: Skin cleansed with soap and water; antiseptic applied to margins of wound; the extensive wound of the back of the leg was excised and the skin sutured; the fracture and dislocation of the ankle were reduced by manipulation; dependent drainage was effected by means of rubber tubes through the stab wound. Plaster was applied.

26/1/41.—Patient has had no pain in the leg. Rise in temperature and respiration rate and some sputum. Has been on sulphapyridine for the past five days. General and local condition now satisfactory.

5/2/41.—Plaster changed because of profuse discharge. On removal it was found that the posterior wound was satisfactory, but that a large area of damaged skin on the upper anterior surface of the leg had separated and was lying as a free slough. This was removed. Wound dressed and fresh plaster applied.

21/2/41.—Patient has been running slight evening rise of temperature, but has made no complaint with regard to the leg. Considerable discharge from plaster. Plaster removed. Posterior wound well healed, anterior wound shows large clear area of granulations, about 6 in. long by 4 in. wide. No surrounding infection. Following change of plaster patient had no rise of temperature. General and local condition satisfactory.

Discussion

The cases investigated were selected from a much larger series as being suitable for complete bacteriological examination from the earliest stages to the final healing. One of us is in process of analysing the clinical aspects of the larger series as a whole. Neither the general composition of the wound flora under closed plasters nor the changes of its composition in the early or later stages have given any clear explanation of the virtue of the closed-plaster method of treatment. We have found no striking difference in flora between our wounds and the open wounds described (Miles and others, 1940) during the present war. We have not seen, as we thought we might see, a disappearance or diminution of pathogenic bacteria under the influence of saprophytic anaerobes or of relatively harmless Gram-negative aerobic rods such as *Proteus* or *Ps. pyocyanea.*

Although it is impossible to assert that *Str. pyogenes* (Group A) is completely innocuous in properly immobilized and protected wounds, it is clear enough that this microbe may be present from first to last in wounds which, under these conditions, heal without obvious complications or gross delay; and the same is true of *Staph. aureus.* But these phenomena, it seems, may also be seen sometimes in open wounds.

The method of treatment, we feel, owes its efficacy rather to its physical and physiological effects than to any specific influence on the bacterial flora (Trueta and Barnes, 1940).

The window-sampling method has proved satisfactory when true access to the tissues is provided, and has enabled us to observe changes in the flora at all periods of treatment and to form provisional views about the reasons for the appearance and disappearance of species, and about the protection afforded by the plaster against gross infection.

Summary

A satisfactory method has been devised for securing bacteriological samples from wounds encased in plaster without interfering with the treatment.

The flora of wounds treated in closed plaster does not appear to differ from that of open wounds, and neither its character nor its fluctuations explain the efficacy of the closed-plaster method. Infection of such wounds during the period of hospital treatment occurs fairly often during changes of plaster, but no cross-infection has been detected at any other time.

It is suggested that the multiplication of bacteria is delayed for some days in wounds which are excised and cleansed within a few hours of the accident. Some organisms appear to be permanently removed by this procedure.

No evidence has been found that *Ps. pyocyanea* or any other organism inhibits the growth of haemolytic streptococci or of *Staph. aureus* in wounds.

The Medical Research Council has provided a part-time grant for one of us (J. O.-E.) and a whole-time salary for a laboratory assistant (W. Fincham), as well as money for expenses. Prof. Gardner owes his leisure for research partly to the University of Oxford and partly to the Nuffield Trust. Prof. H. J. Seddon and Prof. H. W. Florey played a large part in launching the research, and Mr. Elliot Smith collaborated on the surgical side during the early stages. Dr. F. Griffith, whose death we lament, kindly typed our streptococci, and Prof. A. A. Miles struggled nobly and successfully with our anaerobes.

DIABETIC COMA IN A SERIES OF YOUNG DIABETICS*

BY

LESLIE COLE, M.D., F.R.C.P.

Physician to Addenbrooke's Hospital, Cambridge

This clinical study of diabetic coma is based on a series of 24 young diabetics who have attended Addenbrooke's Hospital during the last twelve years. Some of these cases have already been referred to (Cole, 1934). In 23 the disease came on before the age of 15, and in one patient, aged 18, coma was the first symptom. After standardization as in-patients they have attended as out-patients at intervals of from one to three months until the time (1939) when this study was completed (or in fatal cases until death). With the exception of Case 24 they are unselected and comprise all the diabetics attending my department between 1927 and 1939 who were under 15 at their first attendance. Four live in Cambridge and the remainder in towns and small villages within a radius of fifty miles, often at considerable distances from their doctors, and when complications such as infections or coma develop there is often some delay before they can be treated or be admitted to hospital. A series of young diabetics has been chosen for this study because in youth the results are less likely to be complicated by chronic intercurrent disease.

Incidence of Coma

Table I shows that in 24 diabetics coma occurred 13 times: 7 patients had one attack and 3 had two. In 6 coma was the first recognized symptom of diabetes, and in 7 it occurred during the course of treatment. The whole series covers a period of 165 diabetic years, giving an average of approximately one attack every thirteen years for all cases, including patients who had had no treatment before coma. In cases under treatment with insulin the average was one attack every twenty-three years. These figures are quoted to show the incidence in a small group of patients living under somewhat similar conditions and treated on similar lines.

Table II indicates the possible causes of coma. In 6 out of 13 instances the attack occurred in patients in whom diabetes had not been previously diagnosed, and in 4 of these its onset coincided with an infection. In the remain-

*A communication given to the Ulster Medical Society at Belfast in November, 1940.

* Hagedorn-Jensen.

ing 7 instances, when it developed during insulin treatment, an infection was also present in 5. In 4 of the latter the normal dose of insulin had been discontinued on account of either vomiting or failure to take food.

These cases, few as they are, indicate the great importance of infection in precipitating diabetic coma. Occasionally it may develop suddenly in a hitherto unrecognized diabetic (Cases 18 and 20), and rarely in a patient on insulin, without any accompanying signs of infection (Case 13), but in the greater number an acute or chronic infection is a prelude. The most certain way of inducing coma when an infection develops is to stop or reduce the regular dose of insulin.

Usually coma does not occur without some warning history or symptoms to suggest diabetes. Joslin (1935) records 12 cases in a series of 55 in which the diagnosis had not been made before the onset of coma. In children and young adults symptoms may not be present for more than a few days before and may be slight enough for an intelligent parent to ignore. In those who had reported to their doctors, failure to examine the urine in the face of slight but suggestive symptoms was the cause of disaster. The fact that some of these patients were children made the diagnosis more difficult when the essential urine tests were ignored.

Diagnosis of Coma

Some factors which suggest a diagnosis of coma are: previous attacks of coma, untreated or badly controlled diabetes, recent chronic or acute infection, and reduction or stoppage of the regular dose of insulin. The more important warning signs and symptoms are: vomiting, abdominal pain, signs of dehydration, alteration of breathing, sugar in the urine, a positive Gerhardt test, and a raised blood sugar. The incidence of these symptoms in the 13 cases of coma in this series is shown in Table III.

TABLE III.—*Signs and Symptoms in 13 Cases of Coma*

Inability to take regular diet at onset	10
Vomiting at onset	7
Abdominal pain at onset	5
Dehydration	13
Altered breathing (sighing 7; hyperpnœa 6)	13
Sugar in urine (heavy reduction)	13
Rothera's test (strong; 1 weak for 6 hours)	13
Gerhardt's test (absent for first 6 hours in 1)	13
Blood sugar at onset	0.33 to 1.4%

This table shows the importance of vomiting and abdominal pain as early symptoms of coma. If these were more widely recognized as such, insulin would be less often stopped or reduced at the onset. Inability to eat the usual food may be a symptom of coma, and is not an indication to reduce insulin.

The urinary findings were almost constant. Rothera's and Gerhardt's tests were strongly positive in all but Case 6, which is unusual enough to quote.

Case 6.—The patient developed diabetes in 1933 at the age of 10, when he was admitted in early coma after scalding his foot. Diabetes had not been previously diagnosed. He recovered, but for the next five years he was always difficult to control, and mild infections were very apt to upset him. He was tried on various diets and did best on: C. 180, F. 56, and P. 105, with 70 units of insulin daily. He was a sensible boy, with anxious but not very intelligent parents.

His second attack of coma occurred in 1938. Five days before admission he developed a cold in his head. The day before admission nausea and later vomiting came on, and because of this no insulin was given on the morning of admission. He was admitted at midday almost unconscious, with all the classical clinical signs of coma (see Table III). His blood sugar was 1.13%.

The urinary and blood-sugar findings were as follows:

	Rothera	Gerhardt	Blood Sugar
Midday	Faint positive	Negative	1.13%
3 p.m.	Positive	,,	
6 p.m.	,,	Faint positive	
7 p.m.	,,	Positive	0.58%

At 4 p.m., two hours after 100 units of insulin, the CO_2-combining power was 15 volumes %, the blood urea 39 mg. per 100 c.cm., and the blood chlorides 500 mg. per 100 c.cm. Throughout the whole coma there was no marked diminution of urine.

After 800 units in twenty-four hours (700 in the first ten hours) and a continuous intravenous-drip saline, 3,000 c.cm. in twelve hours (the last 1,500 c.cm. contained only 5% glucose), the blood sugar was normal, Gerhardt's test was negative, and the patient had recovered.

This patient, although a very severe case of diabetic coma, showed only a faintly positive Rothera and a negative Gerhardt test on admission, and the latter did not become strongly positive until he had been in coma for at least six hours.

Joslin (1935) states that in coma the urine almost invariably contains a large quantity of diacetic acid, as shown by a positive Gerhardt test, and that only in cases with an associated renal block does one see a negative test for acetone bodies. Richardson (1932) describes a case with a CO_2 of 7 volumes % which had no diacetic acid or acetone in the urine. Payne and Ponlton (1925), Oliver (1926),

and Graham *et al.* (1929) also describe cases. In this patient there did not appear to be renal block, and the explanation of the slow appearance of diacetic acid in the urine is not clear. In diagnosis it is important to remember that although a positive Gerhardt test is present in nearly all cases of coma there are occasional exceptions to this.

Blood-sugar readings of over 1% occurred in three patients: one (Case 6) recovered, the other two (Cases 17 and 18) had both been unconscious for many hours before admission and died. The blood-sugar readings were 1.13, 1.37, and 1.4% respectively. In Case 24 (bronchopneumonia and septicaemia in a hitherto undiagnosed diabetic) the blood sugar was 0.8% on admission. 1,370 units of insulin in twenty-eight hours reduced it to normal, but death occurred a day later. Joslin states that in a series of 293 the blood sugar was over 1% in 11, and of these 4 died. Curtis and Dixson (1928) describe a patient with a blood sugar of 1.68% who recovered, and Haines and Davis (1932) 3 others of over 1%, with recovery.

Treatment of Coma

Diabetic coma is one of the most acute emergencies in medicine, and an hour lost may mean death. The indications are: insulin and glucose to make possible the complete oxidation of fats, fluid for dehydration, sodium chloride for salt deficiency, and warmth and ephedrine for circulatory failure and shock. Symptomatic treatment, which includes gastric lavage for severe vomiting and enemas for constipation, is also important.

Insulin cannot work without glucose, but in the early stages the blood sugar is usually above 0.4% and there is no likelihood of glucose deficiency. When the blood sugar is known to be high it would seem unnecessary to give additional glucose. In the later stages of treatment, when the blood sugar is falling, and particularly when it cannot be watched by frequent readings, it is important to give extra glucose. This also ensures that there is no overshoot into hypoglycaemia. In practice the decision whether to give glucose or not in the early stages depends on the experience of the doctor and the biochemical facilities available. If no blood-sugar reading can be obtained, or if the doctor is inexperienced, glucose should be given from the start.

The dose of insulin is difficult to judge, as there is great variation in the requirements of different patients. Dosage depends on the depth and duration of the coma, the severity of any infection present, the previous dose of insulin and whether this had been discontinued, and what is known of the patient's response to insulin in the past. A patient who goes into coma while balanced on a certain dose of insulin (usually because of an infection) tends not to need such a large dose. Insulin should be given as soon as possible in a dose of from 20 to 100 units, but usually not less than 50, repeated every one or two hours according to the clinical and biochemical progress. In these patients the average dose needed in the 10 who recovered was 236 units in from twelve to twenty-four hours. This average was raised by 1 patient who needed 800 units. Of the 3 fatal cases, 1 died at once, 1 had insufficient insulin, and 1 had 1,370 units in twenty-eight hours.

The early administration of fluid and sodium chloride in the form of normal saline is as important as insulin. This may be given by the mouth to patients who are still able to swallow, and also rectally, subcutaneously, or by intravenous drip. The last method is the one of choice in all patients with severe dehydration. 5% glucose should be added when it is considered necessary. In this way 6 pints or more may be given in twelve hours. Root and Riseman (1938) emphasize the importance of very large amounts of fluid intravenously in severe cases, particularly after a history of prolonged acidosis, unconsciousness for more than six hours, repeated vomiting, excessive dehydration, and suppression or diminution of urine, and quote cases in which 8,000 c.cm. and 6,800 c.cm. were given intravenously in eight and thirty hours respectively, in addition to large amounts of subcutaneous saline. In our series continuous intravenous drip was given to severe cases in which the patients were unable to swallow fluids. When the initial blood sugar was very high glucose was not added until it had fallen. In milder cases, when fluid was given orally, rectally, or subcutaneously only, glucose was added from the start.

Prevention of Coma

In diabetes, even under the best conditions, some attacks of coma are inevitable. The series quoted here, although it cannot be regarded as a random sample of the diabetic population, does indicate how far in one area the management and treatment in the home fall short of the best that could now be obtained. There are two causes for this: (1) failure to diagnose diabetes before the onset of coma (6 cases, 2 fatal); (2) failure to treat diabetes properly during an infection, or when for any reason the usual diet cannot be taken (6 cases, 1 fatal).

Thus in this series of known diabetics under treatment coma occurred only once without an obvious cause. In the remainder proper treatment of infections or failure to take food, by rest, warmth, fluids, glucose, and continuation or increase of the regular dose of insulin, would almost certainly have prevented coma.

The remedy lies, first, in more thorough teaching of the medical student at hospital on the routine management of diabetes. In many teaching hospitals diabetes tends to be treated in separate clinics, and if, as is often the case, a student clerks for a physician who is not interested in the subject, he may fail to receive any practical instruction. Secondly, there must be more thorough teaching of the patients or, in young children, of their relatives. Failure here is often due to insufficient trained staff at the diabetic clinic. Thirdly, co-operation between the patient, the family doctor, and the specialist at the clinic must be closer. It is unfortunate that many diabetics who attend clinics regularly tend to lose touch with their home doctors. This is unsatisfactory, because when an emergency arises at home their doctors are not in possession of the necessary facts.

Diabetes is still, twenty years after the discovery of insulin, one of those conditions in which there is a great lag between knowledge and its application.

Summary

The incidence, causes, symptoms, and treatment of diabetic coma in a series of 24 young diabetics are analysed.

13 attacks occurred in these patients. In 6 of these diabetes had not previously been diagnosed. In 7 which came on during treatment insulin had been discontinued in 4 on account of vomiting or failure to take food. An acute infection preceded the onset of coma in 9.

Most attacks could have been prevented either by earlier diagnosis of diabetes or by proper management of infection during its course.

I should like to thank Dr. J. F. Gaskell, under whom 3 of the cases were admitted, and Dr. R. J. Twort for his help with several severe cases of coma.

DIFFERENTIAL DIAGNOSIS OF CONTUSION OF THE BRAIN AND PSYCHONEUROSIS

BY

WILLIAM A. BREND, M.D.Lond., M.R.C.P.

Medical Referee under the Workmen's Compensation Act; Neurologist to the Ministry of Pensions

The Personal Injuries (Emergency Provisions) Act provides that compensation to civilians injured by enemy action shall be payable only for disablement caused by physical injuries. The diagnosis between contusion of the brain following concussion and psychoneurosis accordingly becomes of great importance, and as it is clear that the distinction presents some difficulty in the certifying of these conditions, it is hoped that the following account of cases I have examined recently for the Ministry of Pensions may be helpful. I have to thank the Director-General of Medical Services for permission to publish the record. The observations are based on an examination of some 300 persons injured in air raids whose disorders had been diagnosed as "shock," "nerve shock," "bomb shock," "concussion," "anxiety neurosis," and "neurasthenia." These people were seen after an interval of three to five months from the incident alleged to have been responsible for their condition, but the notes of those who had been taken to hospital at the time were available. They included persons of all ages from 15 to 82, and of both sexes, with a slight preponderance of women. This long series of consecutive cases afforded an excellent opportunity of comparing the two conditions.

The term "nervous shock," the diagnosis most often used, possesses no medical precision, though it may be convenient and non-committal as a temporary description in the early stages, but its use had been continued in weekly certificates long after accurate diagnosis had become possible. Actually the cases fell into three groups: those showing a typical post-concussional syndrome or chronic cerebral contusion, forming about 30% of the total; those equally clearly suffering from some form of anxiety state—about 50%; and the remainder showing a combination of these two conditions. There was, however, very little correspondence between the diagnoses made at the time of the injury and those which could be made with assurance at a later date.

Influence of Physical Injury

Since the publication of Trotter's papers on head injuries it has been universally accepted that the syndrome of which headache is the most prominent symptom, so often seen after concussion, is the result of physical injury —i.e., contusion of the brain. On the other hand, there is no evidence that physical injury will produce a psychoneurosis, although the contrary view is widely held. If we listen to the evidence constantly given in the county courts we find that many doctors regard it as almost axiomatic that a physical injury may produce or precipitate an anxiety state, which is variously described as "traumatic neurasthenia," "nerve shock," etc., and this is the teaching of at least one of our leading textbooks on medicine. Nevertheless, experience under the Workmen's Compensation Act and in the treatment of ex-Service men suffering from war neurosis has convinced me that where neurotic symptoms become manifest immediately after a physical injury the effect has been produced not by the physical injury itself by the psychic concomitants of that injury. The influence of fear and suggestion may be exercised at three stages: before the accident, when the person is in a state of terror, if only for a brief period; immediately after the physical impact, when he finds himself lying on the ground bleeding and in pain, and, for all he knows, may be going to die at once; and at a later stage when, it having been found that the physical injuries are not serious, he is nevertheless sent to bed, certified by his doctor to be suffering from "shock," and treated as if seriously ill. Months later this type of patient may come up in court still claiming to be suffering from "shock," supported by medical evidence, long after physical injuries have been forgotten or are represented by healed, non-disabling scars. As the belief in the physical causation of "traumatic" neurosis is so generally held it is desirable briefly to summarize the grounds for the opposite opinion.

In the first place there is no clinical difference between "traumatic" neurosis and the neurosis resulting from other agencies. The anxiety state in the "shell-shocked" soldier was found, under treatment, to be identical with the anxiety state in the soldier who had broken down during training without having received any physical injury, and to have its root in the same ultimate type of psychological disturbance. The injured workman presents no features not equally met with in the unscathed. Even with the hysterical muscular contractions or flaccid paralyses occasionally associated with an injury to a limb, the injury has done nothing more than determine the seat of manifestation. That it is still the psychic factor which is operative is shown by the fact that these affections correspond to no anatomical lesions, but to the patient's conception of his injury.

Another significant point is the well-recognized fact that "traumatic neurasthenia" is far more likely to be associated with slight injuries than with serious lesions, yet if physical injury is the cause of the condition it might reasonably be supposed that the greater the injury the greater the likelihood of the appearance of neurotic symptoms. The explanation usually given of this fact is that the neurosis develops to meet a wish—escape from the battlefield in soldiers, compensation or damages in injured civilians—and that the seriously injured person has no need to display such symptoms. Wish-fulfilment may be a factor in some instances, although I have long been sceptical of its playing any material part in compensation cases: exaggeration of symptoms in the hope of obtaining a lump sum is not rare, but this is not a neurosis. Another, and probably more important, consideration is that the seriously injured person knows what is the matter with him, and is therefore much less likely to have suggestion of psychic injury forced upon him. He can see for himself an open wound, and he knows what a broken leg means. The victim of "shock," on the other hand, is suffering from an unfamiliar and almost mysterious entity, and it comes to him with all the force of medical authority. There are reasons for thinking that the use of the term "nervous shock" as a certifiable medical disorder is doing as much harm among civilians as did "shell-shock" among soldiers in the last war.

Finally we may note that we do not expect to find neurotic disorders arising from illness from disease, nor do we hear of "post-operative neurasthenia." Yet, apart from the psychic factors, it is difficult to see why there should be any difference between disease and injury in this respect. Where, during convalescence, such symptoms do manifest themselves, it will, I think, again always be found that they are the result in injudicious medical suggestion or over-concern of relatives acting upon persons already of neurotic temperament.

Importance of the History

If the pathological difference between contusion and neurosis is the presence or absence of organic change the history of the incident becomes all-important. In cases presenting the post-concussional syndrome we expect to find, and do find in the great majority of instances, a history of injury to the head followed by a period of unconsciousness, the duration of which may be quite brief. A few of our patients presenting typical symptoms of contusion stated that they did not lose consciousness; but many of those bombed during air raids are dazed and confused at the time and can give no reliable account of what happened to them. C. P. Symonds (1941) states that the group of symptoms forming what he terms the "minor contusion syndrome" may follow injury to the brain without any loss of consciousness, and that their severity and duration have no constant relation to the degree and duration of the unconsciousness if it has occurred. In a few of our cases it was clear that the patient was not unconscious when first struck, but became unconscious after being rescued. Retrograde amnesia was almost always present. Many of the patients stated that their last recollection was that of doing something homely—"making a cup of tea" was often mentioned—and their next was that of finding themselves in hospital or in an ambulance on the way thereto.

On the other hand a large proportion of those who showed anxiety or other neurotic symptoms had sustained no physical injury at all, but had had terrifying experiences. Here is a typical case:

Mrs. A., a middle-class woman, was, previous to being bombed, apparently of normal mental make-up. In December last eight bombs fell in quick succession in the vicinity of her house, and a house two doors away was demolished. Some of the plaster fell from her ceilings and windows were broken, but she was not hit or cut or physically hurt in any way. She was, however, alone in the house and was terribly frightened. Later her husband came in, and in the morning they went together to see her doctor. He told her that she was suffering from "shock" and ordered her into the country at once. She returned in three weeks feeling no better. Examined at the end of four months, her most prominent symptom is terror, with an urge to micturate as soon as she hears an air-raid warning, and at times she has been unable to avoid wetting her clothes.

Other instances have been furnished by members of demolition squads or of fire services who, without having been physically hurt, have found themselves unable to face the terrors of their work. Some describe themselves as having "collapsed" while actually fighting fires or engaged in rescue work; others have carried on through the particular job but have found themselves sick and shaking the next day and have been unable to go back to duty. One man, who had worked for some months successfully as a member of a demolition squad, dated his symptoms from an occasion when, while working on one house, he was ordered to go to another building which had been destroyed, and found it was his own house and that his wife was buried in the ruins.

Some of the neurotic subjects had sustained cuts or burns or bruises, but there was not a single instance of one of them having also received a severe physical injury.

In estimating the psychic factors in these cases it must be remembered that all the three periods of suggestion of injury which, as we have seen, may play an important part in ordinary accidents are much accentuated in air raids. The antecedent period of terror may last for hours and may be very severe in those who have already once been bombed. After the crash, instead of the prompt help which is the rule in ordinary accidents, the injured person may be in a position of danger for a long time and his rescue may have to be effected while bombs are still falling and buildings are blazing. The person who is unconscious from the beginning is saved the last experience.

The Clinical Pictures

The clinical pictures in the two groups of cases, though superficially alike, are readily distinguishable in most instances. The outstanding feature in contusion is the headache, which is often associated with giddiness. The sufferers complain of it at once, and it may overshadow all other symptoms. They describe the pain as of a stabbing or throbbing character, or as being like that caused by a tight band round the head, and it is the essentially disabling factor in the condition, both for physical and for mental effort. In neurosis, on the other hand, headache is not a typical symptom. It may be complained of, but it is often mentioned only at the end of the story, almost as an afterthought, and it never has the prominence or the apparent severity of the headache met with in contusion.

Inability to concentrate is the other cardinal symptom in contusion, any mental effort tending to make the headache worse. This symptom is best elicited by encouraging the patients to talk freely about their daily affairs—what they do to pass their time, whether they help in the housework, etc. Nearly all will say that they cannot read more than the headlines in the newspapers, as reading makes the headache worse, the eyes sore, and the print become blurred. A characteristic feature is the forgetting to carry out small intentions. The sufferers go out intending to do something, but return without having done it. A woman trying to do shopping now finds she must make a list of the things she is going to buy. "I leave my change on the counter"; "I paid my fare in the bus and then offered it to the conductor again"; "I went to stay with a friend, and left all my luggage in the train," are other actual instances of this condition. The neurotic may complain of inability to concentrate, though if he uses these words he has probably heard the phrase; but when pressed to give specific instances he is often at a loss to find any. He becomes vague, and will make some such reply as, "Well, when I want to do anything." The contused person is often abstracted; the neurotic is usually too self-centred to leave his luggage in a train.

Another point of difference is that the victim of contusion takes a much more hopeful view of his future than does the neurotic. Contusion is an affection from which we expect recovery, and nearly all our contused patients stated that they felt definitely better than they had done a month or six weeks previously. The anxiety state, on the other hand, is a persistent disorder, and those suffering from it will rarely admit to improvement in so short a space of time.

Finally the general mental attitudes are different. The contused person goes straight to his major symptom—the headache. The neurotic is often vague. "It's my nerves," "I cannot explain myself," "I am a perfect wreck," are frequently his opening complaints; while others dilate at once upon their terrors during air raids. As they tell their life stories the differences in their personalities gradually reveal themselves. Many of the contused persons have led active vigorous lives and seem more concerned about getting back to their work than anything else. Two women ambulance drivers seen in succession were obviously minimizing their symptoms in the hope that they would be found fit to resume their duties. Those with anxiety states, on the other hand, belong to the "tender-minded" section of the community. Many of them show great courage in facing their difficulties, but much of this courage must be expended in overcoming an internal enemy from which their sturdier brethren are happily free.

The two groups described above comprise a large proportion of the total and are easily distinguishable, but a certain number of cases in which both sets of symptoms are present to a variable extent offer some difficulty in diagnosis. We have to remember, however, that a person already suffering from an anxiety state may sustain concussion, and the contused person may develop some of the indications of the excessive fear reaction now to be considered.

Influence of Fear

I have so far spoken of "neuroses" in rather general terms, but there is one condition presenting a very definite picture which calls for detailed consideration It was shown by a large proportion, certainly not less than two-thirds, of the cases classed as neuroses, and it was exhibited equally by men and women. These people start off at once by describing the terror they feel as soon as they hear an air-raid warning or gunfire. They begin to shake; some feel sick—"my stomach turns over" is a frequent description—and some even vomit; others have an immediate urge to micturate, and some have attacks of hyperidrosis. They cannot go on with their occupations; some feel impelled to rush out into the street; others run to the nearest shelter. At night they lie awake listening for warnings. Apart from these attacks of terror they have no complaints. Under examination they may show a tremor of the hands and eyelids and a somewhat quickened pulse.

Many of these people have led strenuous lives, often following occupations demanding judgment and "nerve," and no evidence of a neurotic tendency can be found in their personal histories. Their occupations have included lorry-driving and bus-driving, steel-erecting, tunnelling, plate-laying, shunting, etc., and important clerical and administrative work. The women have brought up families, run businesses, and held responsible jobs. They have carried on at their work until the incident occurred which affected them, and some express their profound shame at finding themselves in their present state. Here are two typical instances:

A man, married, with four children, served in France, Egypt, and Gallipoli in the last war. On discharge with the rank of sergeant he became a park-keeper in a London park and subsequently head park-keeper. He had a considerable staff under him and had important A.R.P. duties in the park, which he discharged satisfactorily until one night when a bomb fell near but did not physically hurt him. Since that date he has been unable to go on with his work as he cannot control his terror during air raids.

Another man served in France in the last war and had a good record. For twenty years he was a London bus-driver. In January of last year bombs fell near him, and he saw another bus wrecked and the driver blown to pieces. He cannot now drive in London, and has been placed in a quiet outlying district; but whenever he hears a warning he must go at once to the nearest urinal, and sometimes wets his clothes.

These people feel sure that they would be all right if they were transferred to a safe district, and there is every reason to believe that they will again become normal citizens after the war.

I do not think this condition should be regarded as a neurosis at all. It has not the deep-seated foundations of an anxiety state and is simply an accentuation of the normal response to threat of danger. The reaction caused by a physiological stimulus which is excessive or prolonged is apt to be re-evoked when the stimulus is repeated in much milder form or even when there is merely a threat of such repetition. Examples are not rare in compensation claims. A familiar instance is afforded by the workman who once having had a serious fall is afraid to work at a height again. A youth who rode a carrier cycle in the City recovered completely from a bad accident, with the exception that he dared not ride again in crowded traffic. Many persons are familiar with the condition in a minor form; speaking of a terrifying experience, they will say, "It makes me shudder to think of it again." Looking back, we can see now that many of the cases described as "shell-shock" in the last war fell into this category. These symptoms are really in the nature of conditioned reflexes, and we can postulate no more about their aetiology than that those who display them have a rather greater susceptibility to the fear stimulus than their fellow-men—a remark, however, which might be made about every form of disease. To describe this condition as anxiety neurosis, as ordinarily understood, is to suggest for it an aetiology for the existence of which there is no evidence. We require a term which shall simply define the condition without making any suggestion as to its fundamental origin, and none of our present names meet this need. "Commotional shock" and "emotional shock," terms used by Mott in the last war, have been recently revived; but the former seems to me to amount to concussion, and the latter to be our old friend "traumatic neurasthenia" under a new name. All these words carry implications with them, just as did "shell-shock." It would simplify the problem of handling these cases if they were lifted entirely out of the category of the neuroses; but this can never be done so long as they bear a designation indicating a neurotic origin. I have been accustomed to describe the condition in reports as "exaggerated fear reaction," which leaves the question of the aetiology entirely untouched; but a Greek cloak is kinder, and I suggest "hyperphobosis"* instead. The condition is not new. Job is our exemplar of withstanding adversity, yet he too felt it, and described it in the words: "In thoughts from the visions of the night, when deep sleep falleth upon men, Fear came upon me, and trembling, which made all my bones to shake. Then a spirit passed before my face; the hair of my flesh stood up." (Job iv, 13.)

SULPHONAMIDE TREATMENT OF HYPOPYON ULCER OF THE CORNEA

BY

I. LLOYD JOHNSTONE, M.C., M.D., D.O.

Honorary Surgeon, Worcester City and County Eye Hospital

The sulphonamide group of drugs have found a place in ocular therapeutics in this country, particularly in the treatment of ophthalmia neonatorum. Bellows and Chinn (1939) demonstrated that sulphanilamide penetrates to the ocular fluids and tissues in suitable and efficient therapeutic concentration when given by mouth, but not when applied topically. Luo and P'an (1940) obtained quite different results when they experimented on human eyes. Concentration in the aqueous after instilling 1% sulphanilamide was roughly the same as after oral administration. After applying the drug in powdered form the concentration in the aqueous was from five to eight times as great.

The present article is the record of a clinical experiment directed against a particularly destructive corneal condition—hypopyon ulcer. Because the pneumococcus is often the organism involved in the condition sulphapyridine was chosen as the chief though not the only weapon. The experiment began in June, 1939, with the use of sulphapyridine eye-drops as a 0.07% solution in saline isotonic with the lacrimal secretion.

* ὑπέρφοβος, "very fearful, timid" (Liddell and Scott).

The results were encouraging without being phenomenal. They were a little better than those obtained with the usual antiseptics or optochin and in a parallel series of cases treated by older methods. No eyes were lost either in experimental cases or in controls, except those that had been severely burned by molten metal. The cases treated with sulphapyridine drops had the advantage of quicker recovery and less dense scarring of the cornea. Several of the control cases failed to clear up or recurred, and were finally cured by administering sulphapyridine drops, in one case assisted by subconjunctival injection of the same solution. In a proportion of the cases sulphapyridine has been given orally instead of or in addition to the drops.

During the last few months a number of really severe cases have appeared, and it became evident that only by frequent instillation of the drops could the condition be prevented from deteriorating. A continuous drip was thought to be necessary to effect a cure, and this led to the use of sulphapyridine powder just as one uses calomel powder in phlyctenular ulcers. By this means 3 cases with purulent regurgitation from tear sacs were successfully healed; the tear sacs were subsequently removed—2 after healing of the cornea and 1 while healing was in progress.

Subconjunctival injections of soluseptasine (10%) have been given in a small number of cases in which there was no apparent discharge from the eye and conjunctival redness was moderate. One case—a typical serpiginous ulcer in a coal-miner, with early collection of pus in the anterior chamber—was given such an injection and the patient was allowed to go home—a risk one could never have taken in the past. Two days later the hypopyon had cleared and the ulcer had healed.

Accessory Forms of Treatment

In addition to the sulphonamide every case has had atropine drops and some form of cautery of the ulcer. It is true that some cases are cured by these means alone, but many eyes have been lost when these forms of treatment, aided by every art and antiseptic, have been carried out. It may be possible to omit cautery of the ulcer when using a sulphonamide: that and several other permutations and combinations of sulphonamide treatment remain to be tried.

Suggested Routine Treatment

In the light of experience so far gained the following is suggested as an outline of treatment, to be modified as further experiment may indicate:

1. The patient should as a rule be admitted to hospital.
2. A smear and culture are taken.
3. Atropine is an essential part of treatment, and cautery may prove to be so (see above).
4. In the absence of purulent discharge, possibly even with slight discharge, a subconjunctival injection of two or three depots of soluseptasine (10%) or sulphapyridine (0.07%), about five minims to each depot, should be given. Possibly stronger solutions of sulphapyridine may yet become available.
5. When the organism is known the appropriate sulphonamide treatment should be chosen. For the pneumococcus, sulphapyridine powder should be dusted lightly over the cornea three times a day. For a streptococcus, sulphanilamide powder may be used or soluseptasine continued as drops or by subconjunctival injection. For *Staphylococcus aureus*, sulphathiazole would seem to be the appropriate drug. It has been used in the form of drops in this experiment as 0.1% solution in 1.4% saline, but no definite opinion can yet be offered regarding its superiority over sulphapyridine.

Fine powder (200-mesh) causes no discomfort to the patient, though considerable conjunctival redness arises. So far the practice has been to precede the dusting by one drop of 1% decicaine. Any discomfort complained of has been relieved by removal of the pad and bandage. There is no need for this dressing unless the cornea erodes deeply and requires external pressure.

The total number of cases treated, apart from controls, is 41. Details of cases and comparative tables have not been given, as it is felt that brevity is preferable at the present time.

The two kinds of drops and the sulphapyridine powder were supplied by May and Baker, Ltd., to whom my thanks are tendered. My thanks are also due to the ophthalmic house-surgeons and nursing staff at the Guest Hospital and Eye Infirmary, Dudley, and to the matron and nurses at the Worcester City and County Eye Hospital.

THE CALCULATION AND PRESCRIBING OF INFANTS' FEEDS*

II. THE NEONATAL PERIOD: PRACTICAL POINTS IN THE REGULATION OF FEEDS IN MATERNITY HOSPITALS AND HOMES

BY

HELEN M. M. MACKAY, M.D., F.R.C.P.

Physician for Diseases of the Newborn to the Mothers' Hospital; Member of the Staff of the Medical Research Council

Many experienced sisters in maternity hospitals deal very successfully with feeding problems without the aid of any schedule of feeding, but their experience has to be bought at the price of many mistakes, and is not easily passed on to others unless it can be formulated in some general principles. At a time when many new maternity homes have been established in reception areas, and large numbers of newborn babies must be coped with by midwives with occasional help from a general practitioner, some practical suggestions may be helpful.

Routine of Feeding

Full-term babies are best put to the breast as soon as the mother has had some hours' rest after her labour—say about six hours after birth—and thereafter fed at regular intervals. But there is no object in keeping the baby at the breast for more than a few minutes at a time until the milk has "come in." Three-hourly feeding, giving both breasts at each feed until lactation is fully established, probably suits a larger proportion of newborn babies than a four-hourly routine, but against this must be set the greater amount of rest allowed to the mother by a four-hour interval. In any case nearly all normal babies can be started on five feeds in the day at four-hourly intervals before they are a month old. The time spent over a feed should never exceed thirty minutes and should seldom exceed twenty minutes. Many strong babies will soon take all they need in eight to ten minutes. Long feeds exhaust baby and mother and generally lead to an inadequate intake.

A common cause of lethargy and failure to suck is a subnormal temperature. When a lethargic baby develops slight oedema one can be fairly sure the temperature has fallen to a low level, perhaps on the previous day; moreover, if a baby shows little or no loss in weight after birth he should be examined for oedema. The keeping of a temperature chart for each baby in the maternity ward is strongly advised. Underfeeding, too, is often a cause of lethargy and poor sucking, and hence may establish a vicious circle; but every lethargic baby merits

*Part I of this paper appeared in last week's issue at page 841.

careful consideration, as failure to suck satisfactorily is a symptom in many pathological conditions in the newborn, including intracranial trauma. Midwives are generally familiar with the necessity for having mother and baby in a comfortable position during feeds and with the fact that in the early days many babies need gentle encouragement to suck, and know that if the breast is hard and yields with difficulty manual expression may be temporarily necessary.

Quantitative Requirements during the First Ten Days of Life

Daily weighing of the newborn baby is much to be desired in order to ascertain his progress. If a breast-fed baby is making satisfactory progress and showing normal vigour it is unnecessary to attempt to regulate his intake, as he will do this quite well for himself. Test feeds are desirable, however, if he is not sucking well, if he is not gaining weight fairly steadily from 3 days old, if he loses more than, say, 8% of birth weight (or about 1¼ oz. per pound birth weight), or if he vomits or passes an excessive number of stools. If accurate scales are not available a rough estimate of the day's intake may be made by expressing and measuring the whole of some feeds.

I have suggested a formula based on the baby's birth weight whereby an approximate estimate can be made of the calorie requirements for the first ten to fourteen days of life (Mackay, 1941). On the seventh day (6 days old) and during the second week of life the requirement for twenty-four hours is assumed to be 50 calories per pound birth weight. This calorie allowance is divided by 7, and, on the first day of life the baby is allowed 1/7 of 50 calories per pound birth weight, with an increase of the same amount daily until 6 days old. On this basis a baby by the second week of life would receive 2½ oz. of breast milk per day per pound birth weight. A premature baby doing well and seeming hungry would be allowed more by the end of the second week, all increases being made gradually. As an example, a baby 4 lb. at birth should, according to the formula, have 200 calories on the seventh and subsequent days, or, in order to have a figure divisible by 7, let us say 210 calories; during the first day he would receive 30 calories, or 1½ oz. of breast milk, and this would be increased by 30 calories daily till he reached 210 calories, or 10½ oz. of breast milk, daily at 6 days old. This formula has been shown to give good results with hand-fed premature babies, but it must be remembered that most of the hand-fed premature babies were started on human milk from another mother. The normal full-term baby, however, fed on the breast, and making normal progress, gets considerably less than the formula requirement during the first two days of life, but after that period his average intake is somewhere around that shown by the formula, with large individual variations resulting probably in part from variations in the calorie value of colostrum and early breast milk (Langstein, Rott, and Edelstein, 1913). If it is known that a mother cannot feed her baby, and that consequently he has to be hand-fed from the outset, he may be fed in accordance with the schedule from the first day if breast milk is available. A rather slower start is generally necessary if he is wholly artificially fed, and no harm is done by giving water only to a healthy full-term baby during the first twenty-four hours if so desired.

Calorie-Value of Colostrum and the Use of "Standard" Mixtures of Artificial Feeds

For practical purposes the round figure of 20 calories per fluid ounce can be taken as the average calorie value of colostrum and early breast milk, like that of milk after lactation is established. The differences between individual samples may be large, particularly during the first few days after parturition, and it is said that on the first day the calorie value of colostrum may even be double the average value for breast milk (Langstein, Rott, and Edelstein, 1913). On this ground it would seem illogical if artificial feeding has to be adopted, to give the newborn infant dilute feeds of low calorie concentration. In practice it is found that if this is done the baby is apt to receive an insufficient amount of food because he tires before he has taken the large bulk necessary. Babies from the first day of life can usually take and tolerate feeds of suitable character with a calorie value of 20 per fluid ounce, provided the quantities are carefully graded; and when artificial feeds have to be given I strongly advocate the use of "standard" mixtures of this calorie value (see Part I, p. 842), whatever the infant's birth weight. The quantity of artificial food must always be carefully graded, however, with no sudden large increase. For example, if till the fourth day of life the infant has been put to the breast but has obtained little food he should start with a small supplement, and not suddenly receive the full allowance given in the schedule of feeding for this age, or an upset and a loss of weight are risked. As to the character of the feed, I suggest for premature and feeble babies sweetened condensed milk, 1 in 5 by volume, and for vigorous full-term babies half-cream dried milk with sugar—either the powder already sweetened by the manufacturer and containing about 27% of the calories in added lactose, or unsweetened milk powder to which sugar must be added when the feed is mixed. If these are not available, and full-cream dried milk must be used, a large proportion of the food must be given as added sugar in order to render it as easily tolerated as possible. Of the calories ordered 50% may be in the form of added sugar, in which case the feed would consist of equal volumes of "standard" dried milk mixture and "standard" sugar solution. But the use of full-cream dried milk entails a careful watch for any symptoms of digestive disturbance which necessitate reduction of intake. Since roller-process dried milk with its poorly emulsified fat must always be freshly mixed with water for each feed, the quantity mixed will often have to be in excess of that required for a very young baby, since it is impossible to measure fractions of a drachm of dried milk with any semblance of accuracy. In the case of premature and feeble babies no artificial feeds can approach the results achieved with breast milk.

Vitamin and Mineral Adjuncts

Vitamin D in some form should be started as soon as the baby is well established on his full calorie requirements, except during the summer, when it need not be given to full-term babies lying out of doors daily. Vitamin C should be started next, and it is desirable that all babies, breast-fed and bottle-fed, should receive an iron supplement from about 2 till 12 months or more old.

The Use of Feeding Tables: (a) For Full-term Babies

The use of feeding tables, such as those here given, saves time and trouble in repeated calculations, and in a maternity hospital such tables hung in the ward kitchen will do much, provided they are intelligently used, to keep the feeding on the right lines. It is assumed that all foods given provide 20 calories per fluid ounce. In Table I are shown the volumes of food, according to the schedule, required for babies of different birth weights for each of the first seven days of life. The total for each twenty-four hours is given and also the volume required in each feed, according to whether five feeds or six are taken in the day. For breast-fed babies such a schedule is chiefly of use from 3 days old and onwards for checking the intake if they are not making normal progress, and should prevent mistakes in diagnosis between overfeeding and

10									
Per lb. birth weight ..	Calories 43			Calories 50					

The volumes shown in this table are based on the assumption that all feeds given provide about 20 calories per fluid oz. Normal breast-fed babies take less than the quantities shown on the first and second days of life. No breast-fed baby progressing satisfactorily should be given a supplement. Babies wholly artificially fed should have a rather slower rate of increase than that here shown.

underfeeding—mistakes which are not infrequent. The figures for the first three days can be used for the prescribing of feeds for babies who have to be hand-fed throughout, though if no breast milk is available the increase should usually be rather slower than that shown in the table. It should be carefully explained to nurses that it is not desired to adhere to any schedule rigidly, that in the first two or three days of life normal breast-fed babies do not take the quantities shown in the table, and that babies making normal progress on the breast should certainly not receive supplements up to this schedule; also, as artificial feeds are less easily tolerated than the breast, supplements should always be started gradually.

The ordering of supplements for breast-fed babies in the first ten days of life involves various considerations. Generally speaking, a baby losing weight after the third day on account of underfeeding should have a supplement, but to this there are many exceptions. Some lethargic babies, when given supplements, tend to suck the breast less vigorously; but more commonly lethargy is increased by keeping the baby underfed, and vigour and sucking improve with the giving of a supplement. Great care must be taken to ensure complete emptying of the breasts, and if the baby does not do this with gentle encouragement they should be emptied by hand. If a mother lacks confidence in her ability to feed her baby this may be a reason for avoiding supplements when possible. Big babies, weighing 8½ lb. and more at birth, often require temporary supplementing of their feeds until the breast secretion adjusts itself to their larger needs. An infant should not be discharged from hospital or pass to the mother's unaided care while he is underfed. A mother finding that her underfed baby is "not getting on" often abandons breast-feeding in the second fortnight after parturition, whereas, with a temporary supplement, full breast-feeding could often be resumed. If a supplement is given, the mother's co-operation should be sought in reducing and omitting it, if and when possible. Statistics showing a high proportion of babies discharged from hospital wholly breast-fed are valueless unless it can be shown that the babies were getting enough food.

(b) For Premature Babies

Table II sets out a schedule of feeding for premature babies, calculated from the formula. Some such table is essential in a busy maternity ward, as the time consumed in calculating each day's feed for each premature baby is wasteful, and mistakes are likely to be common. Here again the table is intended as a guide only: a baby wholly

5½ ..	275	13¾	1,100	39									55¾ (1,113)

All feeds to provide 20 calories per fluid ounce. Supplements providing vitamin D and vitamin C should be started cautiously as soon as the baby is established on his feeds, and iron should be started before he is 2 months old.

PRODUCT OF GLAXO LABORATORIES LTD.

Penetrating protection for all wounds

Acriflavine made FULLY effective

The success of acriflavine is due to its capacity to kill bacteria without damaging the tissues. Acriflavine in fact, so far from impeding reactions of the tissues, works *with* them: the effort is *mutual* on the part of tissue and antiseptic. The degree of effectiveness must, however, depend to an appreciable extent upon the medium in which the antiseptic is applied. The ideal medium has been developed in Flavogel—a water soluble jelly base.
In this medium, acriflavine can achieve intimate and continuous contact with every surface and crevice in the depths of the wound, thus obtaining and *maintaining* the maximum bactericidal action. Natural and rapid healing is encouraged, and re-infection prevented. Flavogel is soothing, and lessens the tendency of dressings to adhere to the wound. The tube packing is very convenient for inclusion in all first-aid kits.

FLAVOGEL

ACRIFLAVINE JELLY *In 1½ oz. tubes and 16 oz. jars.*

There is no respite for ADEXOLIN

Although conditions which call for a course of Adexolin are less widespread in summer, there yet remain a number of states (some of which are detailed below), common to all seasons, where this supplement of vitamins A and D is unmistakably indicated. Adexolin has the advantages of being standardised, rational in A-to-D balance, convenient, and acceptable to the patient.

Routine for Infants

Adexolin gives powerful help to normal growth, to dental and skeletal development, and to resistance against infection. The Liquid can be given unnoticed in the bottle feed, or on the infant's tongue. Adexolin Emulsion, miscible with milk, is an excellent tonic for debilitated and under-weight infants.

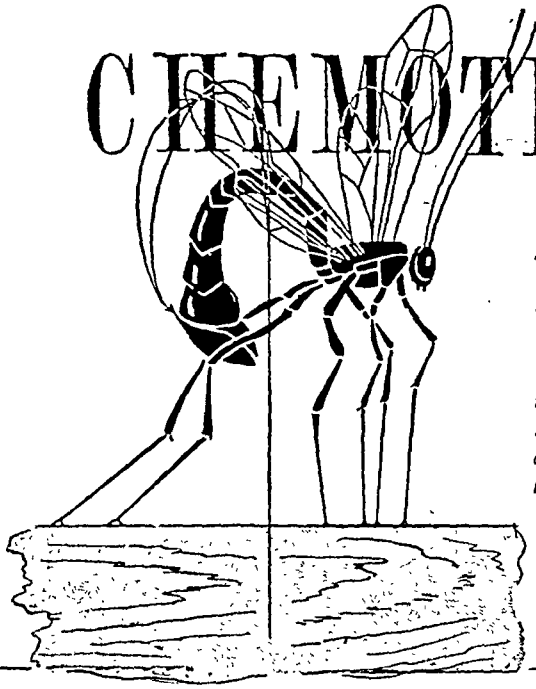
Last 100 days of Pregnancy

Adexolin equips the mother to meet the strain of lactation; and helps to mobilise calcium for the growth of the fœtus. The routine is one Adexolin Capsule a day for the last 100 days of pregnancy.

Adjunct to Specific Treatment

Adexolin, by instituting a nutritional attack upon infection, is of great value as an adjunct in the treatment of gastro-intestinal, nephritic and metabolic disorders; hypo-vitaminosis incidental to restrictive diet therapy; febrile illnesses; debility; and convalescence.

Barrier against Infection



Summer weather this year has to compensate for a winter of unprecedented strain and to build resistance for next winter. In many cases, a routine of 1 to 2 Adexolin capsules a day may well be an essential measure to help combat continual strain and the difficulties of the food situation.

Adexolin Capsules, boxes of 25, 2/-; 100, 6/-; Tins of 500, 24/-; 1,000, 45/-. Tax free. Liquid, ½ oz. phials 2/-; 2 oz. 6/-; 4 oz. bottles 10/-; 8 oz. 18/-. Tax free.

CHEMOTHERAPY

THALESSA LUNATOR

THIS fine insect bores down into wood which is being damaged by the grub of the Sirex (wood wasp) and injects its egg right into the channel made by the grub. Then the larva of Thalessa attacks this grub and feeds on it until it is destroyed, without damaging the wood itself . . . .

Streptocide was the first English brand of sulphanilamide on which a controlled clinical trial was carried out and the results reported upon.

—vide *Lancet* 1937, **2**, 1237.

STREPTOCIDE TABLETS	Oral administration.	STREPTOCIDE SOLUTION 2½ per cent.	Parenteral use and local application.
*STREPTOCIDE POWDER	Oral administration and local application.	STREPTOCIDE OINTMENT STREPTOCIDE CREAM STREPTOCIDE OINTMENT OPHTHALMIC	local application.

* A special apparatus known as the *Streptocide Bacteriostatic Insufflator* is available for the local application of Streptocide Powder into wound cavities.

Complimentary copy of "Chemotherapy with Streptocide" will be sent on application to the Home Medical Department, Hanover Street, Liverpool.

M.J.

artificially fed, or one who takes unwillingly and is inclined to vomit, or who has some abdominal distension, must have a slower increase; a baby obviously hungry and progressing well on breast milk may have the quantities telescoped, so that he receives 50 calories per pound birth weight by the sixth or even the fifth day. Whether the calorie allowance for the day is divided into a smaller or a larger number of feeds must depend on how easily the feed is taken. Abdominal fullness is probably the commonest early sign that the baby is getting rather more than he can well tolerate.

Many small premature babies have temporarily to be fed with pipette or spoon, or possibly with an oesophageal tube. Often administration of carbon dioxide and oxygen through a double nasal catheter for five to ten minutes before feeds increases depth of respiration, brings about better expansion of the lungs, and thereby increases the baby's vigour and his ability to suck. As premature babies are particularly likely to suffer from dietetic deficiency, vitamin D, vitamin C, and iron should be given early and regularly.

Extra Fluid

Some extra fluid over and above that contained in the feed is essential if the best results are to be obtained and inanition fever avoided. A full-term baby taking from the breast requires water given regularly for the first three to seven days, and continued thereafter if the baby takes it readily, as he probably will in hot weather or if living in a very warm room. The quantity will depend largely on the baby's desire to take, but should generally amount to 3 oz. to 4 oz. daily from the second to the fourth or fifth day of life. In my opinion it is undesirable to give sugar in the water.

Premature babies for the first five days of life should, if possible, be given extra water amounting to about as much as they get in their feeds: as the size of the feeds increases the amount of extra water can be decreased. This water is better given between rather than in the feeds, as big bulks are more likely to be vomited, and as it is undesirable to let the food allowance drop because the baby tires before he takes the whole of a large volume of fluid.

Day Sheets

If the best results are to be attained with premature and feeble babies full records are essential. For this purpose it is desirable to supply the nurses in maternity wards with ruled sheets for each infant, on which to record in columns hour by hour anything of importance. The records should include the quantity of food taken at each feed; extra fluid given, and its amount; each stool, and if abnormal its size and consistency; all vomits; the temperature record, if possible four-hourly; the baby's weight at the same time each morning; and any symptoms noted.

Discharge of Babies

If it can possibly be avoided babies should not be discharged from hospital and maternity homes underfed or until they are making satisfactory progress. They should be having not more than six feeds in the day: night feeds mean insufficient sleep for the mother. The conditions to which a baby is going should be inquired into: is the house intact?; will he be sleeping in a wet Anderson shelter or under a railway arch?; is there infection in the home?; can the mother obtain any needful artificial food at once, and are her financial circumstances such that she is entitled to obtain free milk for herself and the baby? The mother should herself have fed and washed the baby before discharge and have mixed any artificial feeds being given, so that she can undertake these things with confidence in her own home. If possible, the premature baby should be getting its full requirements of vitamin D, vitamin C, and iron before discharge, so that the feeding may be something like plain sailing for the mother.

Summary

The routine feeding of newborn babies is discussed, and a formula is suggested whereby their approximate daily calorie needs can be calculated. The advantages are indicated of standardizing artificial feeds so that they contain 20 calories per fluid ounce. Feeding tables are given whereby the food of babies in the neonatal period can be ordered or checked, and indications for supplementing the breast milk intake are discussed

Medical Memoranda

An Unusual Sign in Fractured Skull

The following case may be considered worthy of record on account of its rarity.

CASE REPORT

A man aged 45 was admitted to hospital with a history of having fallen off a bus twenty minutes previously. He was semi-comatose, restless, and incoherent. The pulse rate was 100 and the blood pressure 120/80. The pupils were equal and active. Movement of limbs was apparently full. Babinski's sign was absent. There was bleeding from the left nostril, and he vomited once soon after admission.

Two hours later he was conscious and showed retrograde amnesia, remembering nothing after waiting for the bus. He complained of headache only. Lumbar puncture produced pure blood only Radiographs revealed a fissured fracture of the occipital bone running down from the foramen magnum to the right of the middle line. Forty-eight hours after admission there was "oedema" of the whole scalp, with pitting on pressure. The swelling extended from occiput to sinciput, but did not spread beyond the supra-orbital ridges. There was no scalp wound, no obvious haematoma, and no localized inflammatory swelling such as is seen in Pott's puffy tumour. Twenty-four hours later the oedema had gone. He now complained of dimness of vision of the right eye, and investigation disclosed a complete vitreous haemorrhage with absence of the red reflex. The left fundus showed swelling of the nerve head to the extent of about 2D

Lumbar puncture sixteen days after admission revealed clear fluid with no abnormal features except a stronger Fehling reaction. By this time there was a slight return of the red reflex on the right side with some corresponding return of vision, and the swelling of the left disk was subsiding. The headache improved slowly, and on discharge after seven weeks the patient did not complain of anything except slight giddiness and defective vision in the right eye.

DISCUSSION

The only similar case record found in the literature is that of a child reported by Gottlieb (*Medical Record*, 1935, 142, 511), in which with a fracture of the occipital bone there was a progressive swelling of the scalp and face attributed to an escape of cerebrospinal fluid extending into the subaponeurotic tissues from the epicranial space and thence to the subcutaneous tissues Gottlieb suggests the name "cephalhydroma" or "extracranial hydrocephalus" for the condition. He was able to show radiographic evidence of fluid beneath the scalp, and though this proof is missing in our case it would seem likely that the condition is of the same nature.

P. N. CUTNER, M.B., F.R.C.S.Ed.

London, W.1. W. LEES TEMPLETON, M.D.

J. Parks (*Amer. J. Obstet. Gynecol.*, 1941, 41, 714), who emphasizes the rarity of true diphtheritic vaginitis in the adult, records a case of isolated diphtheritic vaginitis in a woman aged 22. The diagnosis at first made was acute bartholinitis and secondary syphilis, until the patient passed a cast of the vagina in which virulent diphtheria bacilli were found. Rapid healing followed injection of diphtheria antitoxin. Generalized constriction of the vagina ensued.

Reviews

WILFRED TROTTER'S WRITINGS

The Collected Papers of Wilfred Trotter, F.R.S. Oxford Medical Publications. (Pp. 194. 10s. 6d. net.) London: Oxford University Press. 1941.

In every profession there is often a striking discrepancy between the popular estimate of a man and the opinion held of him by his colleagues. Of this Wilfred Trotter was an outstanding example. Too little known by the outside world, he was regarded in the profession as having perhaps the finest mind in twentieth century British medicine. The more closely men were associated with him the greater was their admiration, sometimes reaching " this side idolatry." For his great gifts were equalled by his high character. The unusual combination of the mind of a philosopher with the hands of a surgeon gave him a singular intellectual poise, wisdom, and breadth of view. The publication of his *Collected Papers* is therefore timely and most welcome. Those who heard his Hunterian Oration will be glad to recapture the spell of that occasion, remembering the fascinated audience in the crowded theatre to whom he said, " Nothing brings more certain conviction of a man's death than his memorial. . . . No piety after their death can equal in effectiveness a receptive and sympathetic understanding [of great men] during their lives." In that respect he was fortunate in his own lifetime.

In addition to valuable neurological studies this book gives the clue to his general outlook, which we will endeavour to summarize. He held that at no time in the history of the intellect has the sanitary work of destructive criticism been more needful, yet he succeeded in making this both illuminating and inspiring. The instinctive reaction against a novel idea he explained as due to a subconscious feeling that a new truth involved a threat to the personality. To him a medical career appeared desirable because it is possible in it " to pursue the dying ideal that an occupation for adults should allow of intellectual freedom, should give character as much chance as cleverness, and should be subject to the tonic of difficulty and the spice of danger." It is a practical art, and although we must trust to the laboratory rather than to mere observation for further advances in it, " the affectation of scientific exactitude in circumstances where it has no meaning is perhaps the fallacy to which medicine is now most exposed." " A practical art which pretends to be applied science does not thereby show itself to be progressive, it only shows itself to be quackery." " The exactitudes of science call for the elimination of human faculty as far as possible; the lack of exactitude in the practical art calls for the use and expansion of human faculty as far as possible." Yet, he maintains, we cannot trust to the intellect alone, for psychology has shown that it is after all no more than a human organ with preferences and caprices like the stomach.

The consequences of the confident and uncontrolled use of reason in medicine have been gloomy enough; applied to the general affairs of life the results have been even more dreadful. Guided by such master hands as Aquinas, Calvin, Hegel, and Marx, the intellect has shown itself more deadly than cholera or bubonic plague and far more cruel. Philosophy has been cultivated by many of the ablest minds. " It has evolved innumerable systems each rationally proved by its founder to be true and all inconsistent with one another. An experiment that has gone on failing for 2½ millennia may well make us wonder whether the apparatus is adequate or the method sound." It is not surprising therefore that in recent days we are sometimes advised actually to abandon the use of reason; but this is more often founded on a dislike for its conclusions than on doubts of their validity. Reason is an instrument which is powerful but awkward to handle; like any other instrument it is subject to error. We have to learn how to " calibrate the intellect " for the contemplation of ordinary experience. This problem, his son tells us in a brief introduction, occupied Wilfred Trotter's mind in the last years. If his health had permitted him to elaborate his ideas for making the human mind an instrument of greater practical use it might have proved his most considerable achievement.

It is impossible in this summary to convey an adequate sense of his clarity of thought and beauty of expression. To watch Wilfred Trotter's mind in action was a humbling yet salutary and even exhilarating experience. We may apply to himself the words he used about John Hunter: he worked " faithfully, in purity of heart, and with utter devotion to truth."

INDUSTRIAL MEDICINE

Outlines of Industrial Medical Practice By Howard E. Collier, M.D.Ed., Ch.B. (Pp. 440. 21s. net.) London: Edward Arnold and Co.

To those who are engaged in industrial medical practice it becomes more and more apparent that as a branch of medicine it has become so comprehensive that it cannot be covered adequately by the experience of any one person. The author of this book, however, has valiantly attempted by himself to cover the whole of the subject, and this has inevitably led to some inequality of treatment. The subjects discussed are grouped under the headings of executive duties, advisory functions, industrial psychology, industrial medicine, and industrial forensic medicine. In some parts the book shows evidence of a lack of first-hand experience of industrial medical practice. For example, the Thomas splint is advocated as the best method of treating lower limb fractures by first-aid workers in the ambulance room, and the author proposes that all workers found to have a temperature of 98.6° or over should be sent home; in neither instance is this advice practical. The statement that medical examination of new entrants produces a fall in labour turnover in almost all factories is misleading; and is the author on safe ground in recommending that industry should supply vitamins for night workers? The chapter on industrial psychology does not make a difficult part of the subject very much easier for the reader. The section on industrial diseases is the best part of the book, which concludes with a summary of the various Acts applicable to industrial medicine.

SURGICAL PATHOLOGY

A Textbook of Surgical Pathology. By Charles F. W. Illingworth, M.D., Ch.M., F.R.C.S.Ed., and Bruce M. Dick, M.B., F.R.C.S.Ed. Fourth edition. Churchill's Empire Series. (Pp. 728; 300 illustrations. 35s.) London; J. and A. Churchill, Ltd. 1941.

Although the medical student is not of necessity the best judge of a good textbook, yet he has a very shrewd idea of its general teaching value, and if a book reaches a fourth edition in less than ten years it may be accepted that it must at least offer what the student requires. This is certainly true of Illingworth and Dick's *Textbook of Surgical Pathology*, of which a fourth edition has appeared: but, in addition, quite apart from the student's point of view, this volume is recognized as an excellent exposition of the subject.

A book intended primarily for students should be clearly written in good language, free from ambiguity, well illustrated, and, above all, the balance between the various sections and between different views of any one subject must be fairly held. Judged by all these standards, this

textbook emerges with flying colours. We have tested the information provided by reference to many subjects, new and old, over the whole range and always found a completely satisfying account, free of verbosity but not unduly skimped. The proportionate space devoted to different subjects has obviously received very careful attention, so that while the rare conditions receive a short notice there is no tendency to overload the book at the expense of more important aspects of surgical pathology. This careful balance is one of the outstanding features of the book; it is doubtful if the authors' judgment in this respect could be improved.

There are some 300 illustrations, mostly of high quality, but if one were searching for criticism it could be that some of the radiographs have not reproduced very clearly, a widely recognized difficulty which can be overcome only by the use of full art paper with all its attendant disadvantages. The general production of the book reaches the usual high standard of Churchill's Empire Series. We feel no hesitation in recommending it to the student, and to the surgeon who wishes to brush up his knowledge and to obtain a balanced statement on the new aspects of the subject.

HUMAN EMBRYOLOGY

Developmental Anatomy: A Textbook and Laboratory Manual of Embryology. By L. B. Arey, Ph.D., Sc.D., LL.D. Fourth edition, revised. (Pp. 612; illustrated 35s. net.) Philadelphia and London: W. B. Saunders Company. 1940.

The fourth edition of Arey's *Developmental Anatomy* is described by its author as "essentially a new book." It is well and very fully illustrated, and it covers within the limits of 612 pages nearly the whole field of human developmental anatomy, with in addition a valuable series of illustrations of sections and models showing some of the most important stages of development in chick and pig embryos. At the end of each chapter there is appended a valuable list of references to literature. This, though by no means complete, is sufficiently full to enable the reader to find further and more detailed information on special subjects.

The work regarded from the standpoint of medical or science students is certainly one of the best textbooks on human embryology. One misses, however, much interesting matter, which is dealt with more fully in some of the older textbooks, more especially the practical details which are necessary from the clinical standpoint in order to understand fully and to treat congenital defects of such parts as the lips and palate, the spinal cord and the vertebral column, and of special organs or systems such as the eye or uro-genital apparatus. Also from the biological standpoint this work lacks much of the interest that is inspired by some of the earlier works, which by a few words of reference to comparative anatomy or comparative embryology whet the appetite for further information and extended study. As a well-ordered, dogmatic exposition of the facts of human embryology this book forms, however, a masterly survey of recent work on embryology which deserves the highest commendation, and it will be of great value both to students and to research workers.

Notes on Books

The outstanding success of Dr. A. E. HERTZLER'S *Horse and Buggy Doctor* has encouraged him to embark on the admittedly risky enterprise of a sequel. His title, *The Doctor and His Patients* (John Lane, 12s. 6d.), is rather misleading, because, as he tells us in his preface, the book deals with one aspect only—the complications of marital and family relationships. His outlook has been largely conditioned by the loss of a much-loved daughter, which has led to a highly protective attitude towards children and adolescent femininity. That the well-ordered life of a family united by love is the most satisfactory state in the world is true; that it is difficult to attain, these pages amply testify. The author is obviously well-meaning and sincere, and much, though not all, of his advice is sensible. Most medical men have had unpleasant patients, but Dr. Hertzler seems to have specialized in them. To his question, "Why are allegedly Christian people so interested in the sordid things of life?", we would reply by another—Why publish 316 pages chiefly devoted to their description? Repetition becomes wearisome and blurs the intended effect. It may be urged that he knows his public and the way in which to impress them. Some people may like the discussion of the most delicate topics in language reminiscent of Damon Runyon. We don't.

Notwithstanding all the difficulties of to-day in Britain, *The Public and Preparatory Schools Year Book* for 1941 has made its appearance in customary size and shape, and is published by H. F. W. Deane and Sons at 10s. 6d. This reference work, invaluable to schoolmasters and parents, has served its public for fifty-two years. The new edition records the moves, necessitated by the war, of twenty-nine public schools and 100 preparatory schools to temporary addresses. Besides authoritative information about all the public schools represented on the Headmasters' Conference or belonging to the Association of Preparatory Schools, whose official book it is, the volume contains particulars about the universities and guidance on careers, including useful notes on the medical and dental professions.

Preparations and Appliances

SCREENING CUBICLE FOR SHORT-WAVE DIATHERMY

Before the war short-wave diathermy was finding an increasing application in medicine. There was some complaint that the apparatus used interfered with radio reception, especially television, but efforts were being made to find a solution of the difficulty. A short-wave apparatus radiates energy over considerable distances and any radio receiver adjusted to its frequency can pick it up. With the outbreak of war the expected interference of these sets with the radio communications of the Services led to the promulgation under the Defence of the Realm Regulations of the Control of High Frequency Apparatus Order, which applies to "any apparatus that generates or uses and has a maximum output exceeding 10 watts at a frequency exceeding 10,000 cycles per second, not being wireless transmitting apparatus." Thus the possession of diathermy apparatus, both long and short wave, valve-operated or of the spark-gap type, was restricted to approved hospitals and similar institutions and made conditional upon the provision of screening in accordance with official specifications. Details of screening methods have been published by the Engineering Department of the G.P.O. (Radio Branch).

In some circumstances the screening of a whole room, with a supply of filters for every electrical circuit, may be expensive and difficult. Philips Lamps Ltd. of Century House, Shaftesbury Avenue, W.C.2, have constructed a cubicle which complies with the G.P.O. instructions. It can be of any size, but a convenient one will be 6 ft. in each dimension. It is constructed of sheet metal and 1/4-in. wire gauze. If the cubicle is required to stand in the corner of a room the two sides against the wall may be made entirely of sheet metal instead of sheet metal in the lower half and wire mesh in the upper, the panel arrangement minimizing the wire cage effect. The mains suppression filter and the metal-sheathed lead to the plugs are provided, and the door is of wire gauze with two locking handles to give good contact. There is room in the cubicle for massage couch, chair, apparatus, and the necessary movements of the operator. The cubicle is sectional, so that it can be easily dismantled and re-erected or additional sections added to permit it to contain more than one apparatus.

The screening cubicles can only be supplied to recognized hospitals or institutions which can quote the number of their permit from the Engineering Department of the G.P.O., and the restriction upon possession by private practitioners of high-frequency apparatus still holds good.

ELIMINATING USE OF SURGICAL SPIRIT

We referred not long ago[1] to the impulse which has arisen to overhaul aseptic and antiseptic technique. Preventable sepsis has repeatedly been attributed to defects in time-honoured methods of sterilization, and war surgery, both by its very nature and owing to conditions in which it is sometimes conducted in improvised hospitals, has provided a field in which the effects of imperfect technique soon become abundantly manifest. Although war has magnified the problem for us, it exists under normal conditions and has recently caused much concern in the U.S.A.; the text of our previous editorial was the report of a Congress of the American College of Surgeons at which methods of sterilization and their improvement were discussed from many standpoints and for several days. A remarkable feature of this report was the extraordinary diversity of method employed for sterilizing instruments, and the principal speaker drawing attention to this urged the College whose members he was addressing to undertake the official standardization of satisfactory measures for this purpose. Sterilization technique has hitherto been left too much to the discretion of nursing staffs in theatres and elsewhere, and although some of their traditional methods are open to criticism, these have been so long established that they will not readily be changed without the backing of wide authority.

It sometimes happens that an overdue reform is precipitated by unforeseen circumstance, and that circumstance has arisen with us in the form of an acute shortage of spirit. The supplies of alcohol, and indeed of all other solvents and substitutes for it, are low, and consumption for surgical purposes will have to be drastically reduced forthwith. The War Wounds Committee of the Medical Research Council has therefore considered in some detail the measures which can be taken to economize in the surgical use of spirit, and as spirit is extensively used in various ways for purposes of sterilization, the efficacy of alternative methods has also had to be considered. This situation has in fact called urgently for decisions on matters which have been the subject of leisurely debate and varied practice for many years. Not only have these matters been discussed, but where information was incomplete or any doubt existed actual tests have been carried out in order to verify the efficiency or feasibility of a proposed method. The conclusions reached are embodied in a memorandum which has now been sent to the heads of medical services throughout the country, and instructions based on them will presumably be issued soon to hospital personnel.

Spirit is used in surgery for three main purposes. One of these is the sterilization of instruments, and this practice is condemned in unqualified terms. No one acquainted with publications on this subject even during the past few years can logically dispute this judgment. Pure spirit is a poor disinfectant, by no means always sterile itself, and even when diluted with water to its optimum strength for disinfectant action—at which it rapidly rusts instruments stored in it—it is incapable of penetrating even the thinnest film of material such as blood, and is, of course, powerless in any circumstances to attack spores. It is recommended in this memorandum that instruments should be sterilized by heat: dry heat, if available, is the ideal method for any instrument composed only of steel or glass; the alternative for most is boiling, and it is suggested that whenever possible instruments should be sterilized by boiling immediately before use. Two important pronouncements are made in connexion with this method. The first is that boiling for five minutes in a 2% sodium carbonate solution is lethal to all types of bacteria, including spores. Statements to this effect have been made in the past, but we have authority for saying that these have been verified by stringent tests conducted in this country on behalf of the Medical Research Council within the past few weeks. The second is that "recent tests, as well as the experience of many surgeons, have indicated that the widespread view that boiling blunts the edges of surgical knives has little or no foundation." It is pointed out that scalpels must be protected from damage by contact with other instruments during boiling, either by the use of a separate rack or by wrapping them in gauze. A further purpose for which large amounts of spirit are used is the storage of instruments already sterilized by other means. It is suggested that these may often be placed dry in covered trays or sterile towels, or, alternatively, stored in a watery solution of formalin to which borax is added to prevent rusting.

Another wide and debatable field covered by these recommendations is application to the skin. The large bowls of spirit sometimes provided in operating theatres are more wasteful in proportion to their usefulness than any other use to which spirit is put, and are to be prohibited. The main object of immersing the hands in spirit before putting on gloves is to dry them, and this can be achieved by the use of a sterile towel. This condemnation includes the bowl provided in the theatre for rinsing the gloved hands during the operation itself. No mention is made in this memorandum of the solution of mercury biniodide in spirit which is so much favoured for a variety of purposes, but we venture to suggest that its use might well be abandoned altogether; it is greatly inferior in disinfectant power to a solution of mercury perchloride in water; and in any event mercury salts themselves should be employed with economy.

The sterilization of skin before operative incision is admittedly a purpose for which alcoholic solutions are useful, owing to the rapidity with which they evaporate, leaving their dissolved constituents *in situ*. To overcome the drawback of antiseptic solutions made up in water the only requirement is patience, and it is recommended that any of the aqueous antiseptics specified should be allowed three minutes to act and to dry before the operation is begun. Spirit is also considered superfluous in many cases for prevention of bed-sores; alternatives are careful drying after washing and dusting with talcum powder, or, for dry skins, massage with a mixture of zinc oxide and castor oil.

[1] *British Medical Journal*, 1941, **1**, 246.

This review of these new provisions is not intended as a complete guide to the methods recommended, but merely as an indication of their nature and an explanation of their necessity. It must clearly be understood that these changes, whatever their merits, will inevitably be imposed on surgical staffs by the impossibility of obtaining enough spirit to continue the methods to which they are accustomed. We have also endeavoured to make it clear that merely theoretical discussion is not their only basis: where *ad hoc* investigations have seemed necessary in order to confirm the efficacy of some proceeding or to reveal the extent of its possible drawbacks, actual tests have been made to settle the point in doubt. Whether a committee with a free hand to improve sterilization technique and unfettered by the need for drastic economy in a particular type of material would have made exactly the same recommendations we do not know. But undue reliance on spirit as a disinfectant is certainly one of the major faults in existing practice, and it therefore so happens that the ends of both economy and efficiency are served by the same means.

STANDARDIZATION OF DIPHTHERIA PROPHYLAXIS

To those who have not been continuously engaged in immunization against diphtheria the evolution of the procedure has been confusing and the choice of prophylactics difficult. From the original toxin-antitoxin mixture of von Behring we have moved to formol toxoid, toxoid-antitoxin mixture, toxoid-antitoxin floccules, and alum-precipitated toxoid. There seemed to be no finality as to either the reagent to be preferred, or its dosage, or its time-spacing. For these among other reasons, a Committee on Immunization of the British Medical Association in 1935 summarized the knowledge available at that time, and the same purpose was served in 1940 by a committee of the American Public Health Association.[1] In some respects American practice differs from ours, but the outstanding contrast lies in the success achieved in Canada and the U.S.A. in the application of specific prophylaxis, although many of the improvements in the reagents have been made by workers in this country like Parish, Glenny, and their colleagues. Our relative failure may partly be attributed to the confusion we have mentioned. To some extent the prospect is brighter since the Ministry of Health began publicly to advocate immunization with some vigour toward the end of last year, and practical guidance (a little too brief) was afforded in an official memorandum.[2] While four of the five reagents mentioned above are in common use, it is now generally agreed that at least for young children, on whom a special effort should be concentrated, alum-precipitated toxoid is the prophylactic of choice. It may be noted, however, that while the Ministry states that the usual practice in this country and the U.S.A. is to administer doses of 0.2 c.cm. and 0.5 c.cm. at four-weekly intervals, the Emergency Laboratory Service of the Medical Research Council, which now acts as the Ministry's distributing agent, advises 0.1 c.cm. and 0.3 c.cm. with the same time-spacing. If the latter dosage is sufficient it would be wasteful to give more.

It is this continuing state of uncertainty which has stimulated Dr. J. Tudor Lewis to discuss the whole matter in a timely and useful book.[3] By closely reasoned and clear argument, informed by the quoted accounts of others and his own fairly extensive experience in Croydon, he tries to reach a plan which can be adopted universally. It may be said at once that the scheme which commends itself to him is a still further variant of those propounded by the Ministry and the Emergency Laboratory Service. If the use of other reagents be disregarded—and there is not much difference of opinion as to how they should be used—he advocates the following procedure with alum-precipitated toxoid: for children under 8 years of age a first injection of 0.5 to 1 c.cm. intramuscularly into the extensor aspect of the left arm, followed in not less than a month by 0.5 to 1 c.cm. in the right arm; but for children over 8 years a first dose of 0.1 to 0.25 c.cm. and a second (if the first causes no reaction) of 0.5 c.cm. with the same interval and change of site. The interval, it will be noted, must always be at least a month—an important point which still does not seem to be widely enough realized. The larger initial dosage for young children is designed to compensate for their less ready reaction to antigenic stimulus, probably because they have been subjected less to the "priming" of latent infection, and it is practicable because they are less likely to have uncomfortable reactions. Moreover, the degree of immunity derived from this one injection, if the child fails to return for a second, will still be considerable. Indeed, although he is emphatic on the desirability of two injections, Lewis is not so dogmatically condemnatory, as some British and Canadian workers are, of the practice in some American quarters of giving alum-precipitated toxoid in single doses. As to the age drawing the line between his two methods, he would no doubt admit that this might vary with the type of area and its past experience of diphtheria, in much the same way as he suggests that this should lead to a decision whether preliminary Schick tests ought to be done. In rural or other protected groups of the population children even over 8 years may show a resistance to immunization comparable to that of the average younger child in town. It would appear to follow, if Lewis is right as to dosage, that the schemes approved by the Ministry and the Emergency Laboratory Service are not universally the best for every area and every age group. They may, however, be sufficient for practical purposes, especially if waning immunity is revived a few years later by a further dose—for instance, on school entry among those primarily immunized in infancy.

In recounting the few disasters which have occurred in the process of immunization Lewis conveys the impression that nothing of the kind has happened where a British reagent has been used. The omission to mention the "Ring case" is hardly justified by the fact that the preparation used was exonerated in a court of law and was almost certainly not the cause. There was evidence that tuberculosis occurred as the result of immunization, and there is little more reason to exclude this incident from record than there would have been for treating the inexcusable contamination of the prophylactic with staphylococci at Bundaberg in the same way. Every misfortune of this kind has its lesson, which Lewis in another part of his book drives home by quoting the investigations into sterilization of instruments which arose out of the events at Ring.

CYSTICERCOSIS

The recent outbreaks of trichiniasis in this country have drawn attention to the fact that raw pork is a more popular item of the diet of certain groups of the population than the health authorities realized. This shows the necessity for thoroughly cooking all pork in order to prevent infestation not only with *Trichinella spiralis* but also with the less common *Cysticercus cellulosae*, the cystic stage of *Taenia solium*. This tape-worm, a rare parasite in England, is common in Asia and in many parts of Europe. Most of the cases seen in this country have been in soldiers who have served in India, where the sanitation has been defective, the habits of the people less cleanly, and pollution of ground and water supplies with human excrement possible. Apart from those suffering from intestinal infestation with the adult worm, many, as recorded by MacArthur[1] and more recently by Blyth[2], have presented themselves as cases of epilepsy due to infestation with the cystic stage (which occurs more usually in pigs).

The adult parasite *Taenia solium* lives in the intestine in man, attaining when mature a length of about 10 feet composed of approximately 800 segments. The terminal ten or twelve segments, or proglottides, consist of the uterus and its branches, which contain about 30,000 ova. If these ova, which normally develop further in the pig, are swallowed by man, small six-spined embryos are liberated in the stomach; these pass into the blood stream and thence to all the tissues of the body. Brailsford[3] considers that autoinfestation through the regurgitation of ripe proglottides of an intestinal *Taenia solium* into the stomach happens very rarely; otherwise infestation would be much more extensive than in the worst cases that are seen. The embryos develop in the connective tissues, particularly of the musculature, and in the central nervous system. If they reach a favourable site, each develops into a *Cysticercus cellulosae*. Many of the embryos proceed to full development, while others die, disintegrate, and become calcified. The fully developed embryo can live encysted in the musculature for some years. While alive the cyst is about 3/8 in long and 1/4 in. broad; it is flaccid and its wall is elastic. It appears to cause little reaction, beyond the development of a fibrous capsule, in the adjacent host tissues. After an interval of several years the inimical products in the host tissues cause the death of the parasite. This is followed by necrosis, disintegration, absorption of fluid, shrinkage, and deposition of calcium.

Special feeding experiments have shown that within a month of the ingestion of ova the parasites begin to develop in favourable sites, and that within four months the embryo is fully formed within its cyst. But in contrast to human trichiniasis there are few or no symptoms until probably several years after infestation. Then the patient may notice painless nodules in the subcutaneous tissues; they are either mature, live, or dead cysts. It is often stated that the central nervous system is more frequently infested than the skeletal tissues, but Brailsford considers this an erroneous impression. He thinks it is due to the fact that the symptoms resulting from infestation of the brain or eye often appear before cysts in the subcutaneous tissue are demonstrable, either clinically or radiographically. He has for many years made a careful study of the condition, examining some thousands of *x*-ray plates of patients in both general and mental hospitals. He believes, in contrast to MacArthur, that the number of cases of epilepsy and cerebral disorders due to infestation with *Cysticercus cellulosae* is very small. The degeneration and calcification of the contents of the parasitic cyst do not take place so readily in the brain as in the musculature: consequently patients may show signs and symptoms of cerebral involvement. As long as ten years after calcified cysticerci have been radiographically demonstrated in the connective tissues of the musculature, radiographs of the skull may not have shown any evidence of the presence of such parasites in the brain. Brailsford suggests that in cases of epilepsy where infestation is suspected a radiograph should be taken of the muscle of either the thigh or the calf, and if these fail to show cysticerci it is unlikely that radiographs of the skull will. These cysts should never be confused with the cystic stage of *Trichinella spiralis*, for the latter is so small that when fully developed it is only just visible to the naked eye. Most cases of infestation of the central nervous system will end fatally, in contrast to cases of trichiniasis, to which, according to Bercovitz,[4] there are no permanent sequels. Though not a common condition at present, cysticercosis may need to be watched for in future after the wide distribution of our armies abroad.

VARIATIONS IN AGE OF ONSET OF HEREDITARY DISEASES

It is well known that in the case of many hereditary human diseases age at onset is a very variable feature. It is further known that there is often a marked tendency for sufferers belonging to the same family group to resemble each other in this respect. It may also be accepted that age at onset is closely associated with the selective disadvantage of a gene: a very early onset in the case of a serious condition makes the reproductive rate *nil* or almost *nil*; while a very late onset may yield a rate of almost unity. Variations in age at onset may come about in any one of three ways. First, there may be two or more main genes, any one of which produces a clinically similar condition, but age at onset will vary according to which gene is responsible. Secondly, a single main gene may be responsible, but modifying genes may determine the time at which the effect is produced. Finally, in the presence of a single main gene environmental conditions may favour an early or a late onset. Professor J. B. S. Haldane[5] has made an analysis of these possibilities using data recently published by Dr. Julia Bell[6 7 8] on several inherited conditions. He points out that if the first of the three possibilities is realized the correlation between sibs as regards age at onset and also between parent and child would tend to be very high. It would not of course be unity, because there must certainly remain some residual variation even when the same gene is concerned. If modifying genes were responsible for the observed variations the correlation would tend to be of the order of 0.5. If, on the other hand, environmental influences were chiefly responsible we should expect to find lower correlations, the figure for sibs, however, being higher than that for parent and child because sibs tend to share a more similar environment. There should also occasionally be associations with other factors—for example, sex or occupation. In the case of the hereditary ataxias and spastic paraplegia the tendency for members of a family group to exhibit a similar age at onset is very strong indeed. The correlations exceed 0.5 with a high degree of significance. There can be no doubt that in these cases any one of several main genes may cause the condition, and the observed variations are to be attributed above all to this circumstance. The same result is found in the case of glaucoma and peroneal atrophy. Even in these cases, however, there is the suggestion that modifying genes may occasionally play an important part, because a few pedigrees display very large variations. It is probable that about 1% of the population carries modifying genes which greatly delay

the onset of Friedreich's ataxia. In the case of Huntington's chorea the correlations are of the order of 0·5. It may well be that in this instance a single main gene is responsible and that variations in age of onset are indeed due to modifying genes. The same may be true of Leber's optic atrophy, but this condition is a genetic curiosity. No Mendelian scheme fits the facts of its transmission, and at the moment it can only be unsatisfactorily labelled as a possible case of cytoplasmic inheritance: unsatisfactorily because of the extreme rarity of such transmission, particularly in the higher forms. Huntington's chorea appears to fulfil the criteria demanded by Fisher's theory of the evolution of dominance, selection through the ages having produced an ever later age at onset of the disease. The ultimate tendency may be for the condition to become in effect recessive, when there would follow a spread of the gene with perhaps the appearance of a much more pronounced condition due to the simultaneous presence of two of the abnormal genes.

TUBERCULOSIS IN DOGS

It is known that dogs may become infected under natural conditions with human and bovine tubercle bacilli, but the recorded incidence varies from 0.04% to 1.0% in statistics based on clinical work and from 0.83% to 5.6% in figures obtained at necropsy. Lovell and White[1] found that 4.6% of the dogs brought to the clinics of the Royal Veterinary College Hospital, which were mainly the property of poor people living in London and, therefore, not random samples, were tuberculous at necropsy. Of twenty-two dogs with tuberculosis nineteen were males and three were bitches; the ratio of males to females among those coming to necropsy during the same time was only 3:1. Eight of the twenty-two were wire-haired fox terriers (36%), but of 350 received consecutively for necropsy only 11% were of this breed. (Hjärre[2] in Stockholm found the highest incidence among Irish setters and fox terriers.) In three dogs the main symptom was swelling of the mandibular lymph node, while one had no ill-health apart from thickening of the spermatic cord. With primary involvement of the mesenteric nodes the symptoms were usually vomiting and diarrhoea of a few weeks' duration, and when the lungs were solely or principally infected there was a history of loss of condition and coughing for periods varying from a few days to a year. Involvement of the serous membranes was common. There was tuberculous pleurisy in nine of the twenty-two dogs, with effusion in six; in five of these the omentum or parietal peritoneum was also involved. Altogether there were seven cases of tuberculous peritonitis, which was accompanied by effusion in only one instance, and in five of them there were also omental lesions; the latter were seen in three additional cases. There was one case of primary tuberculosis of the tonsil. Lovell and White failed to find healed tuberculous lesions. In only four of the twenty-two animals was the bovine type of bacillus isolated, and in all these the mesenteric nodes were affected. This relative incidence of human and bovine infection is comparable with that found by other workers: approximately three-quarters of natural cases of tuberculosis in dogs are caused by the human bacillus. This appears to be due more to the opportunity for infection than to any difference of susceptibility to the two types. There is only one record of infection of avian origin. A definite history of tuberculosis in the owner (or other member of his family) of three of the affected dogs was obtained. In Stockholm, Hjärre and Herlitz[3] examined the history of the household in twenty-five cases of canine tuberculosis, and found evidence of tuberculosis in six. The authors failed to produce evidence of transmission of the disease from dog to man, but they emphasize the danger that might arise from infected sputum and urine of tuberculous dogs. The paper by Lovell and White should help to draw the attention of workers to an aspect of the tuberculosis problem in man which has hitherto been ignored.

AMERICAN MEDICAL WOMEN'S GESTURE

In the middle of the last war, as a result of a widespread desire of medical women in the United States to participate in war service, the American Medical Women's Association set up an organization known as "The American Women's Hospitals." The first unit sailed for Europe in June, 1918, and Hospital No. 1 was established in France in the following month. The armistice, however, came about three months afterwards, so that actual war service was very brief. The organization continued in being, and directed its energies to the care of the sick and the prevention of disease in many European and Asiatic countries, fully or partially maintaining and conducting over seventy hospitals and three hundred clinics. In London it assisted in the endowment of a bed in memory of Dr. Elizabeth Blackwell in the Washington Ward of the Royal Free Hospital. A year ago the Medical Women's Federation received from Dr. Esther P. Lovejoy, who has served for many years as chairman of the American Women's Hospitals, the offer of a monthly contribution for the relief of civilians in the bombed areas of Great Britain, and up to date £3,000 (12,000 dollars) has been received, and a further 1,000 dollars (about £247) a month has been promised. These sums have enabled the executive committee of the Federation to send financial help to many districts in the London area and a dozen or more other cities which have suffered air bombardment. Medical work naturally had first call, but it has not been possible to restrict the help to that. It has included the provision of clothing for evacuated children, arranging a period of quiet convalescence for women who have suffered in bombed areas, feeding the homeless, supplying furniture for district nurses whose home had been destroyed, giving help in the shelters, especially for recently confined women and their babies, and assisting the blind and crippled. One medical mobile unit, staffed by a medical woman and trained nurses, has been helped, and in another case some help has been given to enable a large provincial hospital to open up again after severe damage. Just before the outbreak of war Dr. Lovejoy described the twenty-years service of "The American Women's Hospitals" in a book, and she said that the organization should carry on, hoping for peace and constructive work, but ready for any emergency which might arise. The emergency very quickly arose, and it is a happy thing that American and British women doctors should be collaborating in this way, on the one side furnishing the money and on the other side administering it, for the relief of suffering due to the war.

We regret to announce the death at the age of 87 of Dr. R. Percy Smith, F.R.C.P., consulting physician for mental diseases, St. Thomas's Hospital, and a former medical superintendent of Bethlem Royal Hospital.

The following appointments have been made by the Council of the Imperial Cancer Research Fund for the ensuing year: Chairman of the Council, Prof. H. R. Dean; vice-chairman of the Council, Sir Cuthbert Wallace, Bt.; Elizabeth Wills Allen Fellow, Dr. L. Foulds; Alice Memorial Fellow, Dr. R. J. Ludford. Prof. James Young has been appointed a Governor of the Fund by the Royal College of Surgeons of Edinburgh, and Prof. T. J. Bosworth by the Royal Veterinary College and Hospital.

CHEST SURGERY IN WAR

This is one of a short series of articles based on lectures given at the British Postgraduate Medical School, Hammersmith

ABDOMINO-THORACIC INJURIES *

BY

GORDON GORDON-TAYLOR, M.S., F.R.C.S.

Temporary Surgeon Rear-Admiral

TREATMENT OF PENETRATING ABDOMINO-THORACIC INJURIES

The surgery of the thoracic wall and cavity is being dealt with in this series of lectures by those most expert in the surgery of this region. My contribution is therefore only concerned with the surgical treatment of injuries of the diaphragm and of those abdominal organs whose anatomical proximity renders them specially vulnerable in cases of diaphragmatic wounding.

I. Wounds implicating the Liver

The dimensions and the velocity of the missile play an important part in determining the type of hepatic lesion, which may be almost protean in character; large fragments of liver may be torn off, and as much as one-third of the right lobe has been found loose in the peritoneal cavity of a patient who recovered from a penetrating abdomino-thoracic injury in the last war.

Before their total destruction the examination of museum specimens in the College of Surgeons collection illustrating gunshot wounds of the liver revealed many lesions for which surgery must be futile or incomplete: thus it would be impossible by operative measures alone to prevent infection throughout the length of a ragged track running from the right lateral surface of the organ to its extreme pole on the other side of the body. In many cases of liver injury due to enemy action there are few arresting clinical signs, and it is significant that out of all the penetrating injuries of the abdomen which recovered in the last war without operation the wounds were mostly situated in the liver area. *Surgical intervention* directed towards the liver is indicated under the following circumstances only: (1) *gross haemorrhage from the liver*, which mainly depends on whether large veins in the organ have been injured—haemorrhage otherwise ceases spontaneously, as does oozing of bile, unless main ducts are severed; (2) the association of some thoracic or another abdominal lesion demanding exploration; (3) the retention of a missile in the liver, especially a large missile in an accessible position in that organ. In the case of severe laceration of the liver packing may be necessary to control haemorrhage. In some such patients the diaphragm may be sutured, and the thorax closed in the approved manner with airtight drainage of the pleura by means of a Malecot's tube inserted through a separate intercostal incision. The gauze pack is brought out through another separate incision in the anterior abdominal wall. In other cases the diaphragmatic opening may be enlarged parallel with its fibres from mediastinal to lateral border; the diaphragmatic edges are now approximated to the intercostal muscles and the pleura is thus shut off from the drainage track.

Early jaundice in cases of hepatic injury may be present, and is usually slight and evanescent; the possibility of a collection of bile in peritoneum or pelvis should always be considered. *Late jaundice* has a much graver significance, and indicates serious infection.

Secondary hepatic haemorrhage in penetrating abdomino-thoracic injuries is almost always fatal, and is usually associated with signs of sepsis such as pain, elevation of temperature and pulse rate, abdominal pallor, restlessness, and loss of strength.

The formation of an *intrahepatic abscess* round a retained fragment may be dealt with successfully by surgical measures.

II. Gunshot Injury of the Spleen

A study of the specimens of *gunshot injury of the spleen* in the War Collection formerly housed in the Royal College of Surgeons used to suggest that wounds of that organ are frequently complicated by damage to adjacent viscera; yet in some collected clinical series it is stated that in more than half the cases of splenic injury revealed at operation there was no damage to other abdominal organs. This was certainly not my experience (Gordon-Taylor, 1939), which is in agreement with that of Major Jolly in his surgical work with the Spanish Republican Army (Jolly, 1940).

The propriety of primary splenectomy in cases of gunshot injury will still remain a subject of controversy. The removal of the organ should certainly not be resorted to light-heartedly, but in my opinion the procedure has not greatly increased the risk. The suture of the spleen may not be difficult when the organ is approached through the chest and diaphragm, but when explored by other routes cobbling of the organ is wasteful of time and may leave a sense of insecurity. Jolly (1940) and some of the Spanish surgeons write enthusiastically of splenectomy.

Numerous cases of successful transdiaphragmatic splenectomy in left-sided abdomino-thoracic wounds were recorded in the war of 1914-18, some of which were associated with the operative repair of injuries to the stomach (Richard Charles, Gask, J. E. H. Roberts, Lockwood, Bryan, Gordon-Taylor, etc., and very recently by Valentine Logue). Recovery has even taken place in cases of left-sided abdomino-thoracic wounds in which left-sided nephrectomy as well as splenectomy had to be performed for complete disruption of each organ (Gordon-Taylor).

III. Wounds of the Pancreas

These injuries were less frequent in the war of 1914-18, or at any rate were less often recognized, than injuries of any other of the abdominal viscera. The intimate anatomical relation of the gland to the large blood vessels doubtless explains the paucity of wounds coming under the observation of the casualty hospital surgeons; doubtless some were unrecognized and were designated retroperitoneal haematomata. I have knowledge of only three abdomino-thoracic injuries implicating the pancreas in which recovery took place (Saint, Alan Curry, Gordon Bryan).

IV. Injury to the Kidney

Each kidney is equally liable to damage. It was estimated that in 40% of gunshot wounds of the kidney investigated at an English surgical base in France during 1914-18 the thorax was also implicated. The propriety of immediate operation on the kidney in abdomino-thoracic wounds demands even more careful consideration than in purely abdominal injuries. Probably the best course is to excise the wound leading down to the damaged kidney; the organ can then be inspected and any foreign body removed.

* Concluded from p. 864.

In the majority of cases the renal injury plays a minor part in menacing life, and only for severe haemorrhage, a hopelessly pulped organ, or gross damage to the renal pedicle is primary nephrectomy indicated. In about 20% of cases of gunshot injury of the kidney in the last war life was threatened by secondary haemorrhage, consequent on sepsis, a retained missile, or an infarct of the kidney produced by damage to some branch of the renal artery.

V. Injury to the Hollow Organs

Of hollow organs the *stomach and splenic flexure of the colon* are those most liable to injury, in suitable cases transdiaphragmatic laparotomy affords excellent access to these organs. Concomitant involvement of the *small intestine* denotes a more vertical track of the missile, and demands a separate approach or a much-extended incision. Each measure, though necessary, increases risk to life. Multivisceral damage also augments mortality, and vertical wounds, which may even extend from supraclavicular fossa to femur, tend to be very fatal.

The possibility of injury to the *duodenum* must be borne in mind, and any haematoma in its vicinity should be suspect, lest a retroperitoneal rupture of this fixed part of the small gut be overlooked. These cases were very fatal in the last war; successful cases have recently been operated upon by Rex Williams, Henry Thompson, and Hedley Atkins.

Summary of Treatment

1. In many traversing (through-and-through) abdomino-thoracic wounds of the right side produced by a small fragment no immediate active surgical treatment is required, provided that: (*a*) no gross damage has been inflicted upon the thoracic or abdominal wall—fractured ribs, explosive effect, etc.; (*b*) the direction of the track of the missile does not appear to compromise the general peritoneal cavity or suggest the desirability of its exploration; (*c*) the signs of abdominal haemorrhage or of injury to a hollow viscus are clearly absent.

2. In cases of right-sided abdomino-thoracic wounds in which a small fragment is retained in an inaccessible position in the substance of the liver an expectant line of treatment is the correct procedure; accessible fragments, unless of small dimensions, should be sought and removed.

3. When there is an open, blowing thoracic wound or a "stove-in chest," the chest wound should of course assume chronological priority of treatment.

4. If the position of the wound of entry and exit in a left-sided abdomino-thoracic wound adumbrates a track implicating that fatal left subphrenic area of the abdomen, or if a radiograph demonstrates a fragment of metal retained in this region, the thorax should be dealt with first and access to the upper abdomen obtained through the diaphragm.

5. When the thoracic injury appears insignificant but there is evidence of severe widespread intraperitoneal damage, especially involvement of hollow viscera, the abdomen should be explored through an appropriately placed laparotomy incision. This instruction applies to wounds of thorax and abdomen produced by the same or by separate missiles.

6. When the thoracic injury seems slight and when the evidence of a radiograph or the direction of a missile track in a through-and-through wound suggests an extra-peritoneal course of a small fragment, such an abdomino-thoracic injury may often be left alone.

If in such cases there is evidence of injury to the kidney the parietal wound down to the kidney should be excised, the organ investigated, and any foreign body removed.

7. In cases in which the thoracic wound is situated low down on the lateral or antero-lateral aspect of the chest access to both supradiaphragmatic and infradiaphragmatic areas may be obtained by cutting through the costal arch after the manner of Bland-Sutton, Duval, Bérard, etc.

8. If an abdomino-thoracic injury has been approached from the abdominal aspect, it is important not to waste time trying to complete a difficult suture of the diaphragm in a critically ill patient, unless the aperture in the midriff is so large that immediate or early herniation of the abdominal contents is certain to occur.

Prognosis

In one large series from the war of 1914-18 it was found that operated abdominal cases (excluding abdomino-thoracic injuries) gave a recovery rate of 51%; while abdomino-thoracic wounds operated upon produced a recovery rate of 44.5%. But some series of abdomino-thoracic cases in the casualty clearing zone gave a more favourable recovery rate than this: in the autumn of 1918 it attained the figure of 66.6% in the hands of certain surgeons in the British Fourth Army; and some operators (Jack Anderson, Saint) who were perhaps fortunate in their percentage of right-sided cases saved as many as 70 and 80% of their patients (Gordon-Taylor, 1939).

Wounds that traverse the diaphragm from below upwards are said to be more grave than those in which the missile has passed from thorax to abdomen. In the former group an intestinal injury increases the seriousness of the prognosis.

The mortality figures attending the surgical treatment of injury in one campaign are scarcely comparable with those of another war at a different period, in which the type of enemy missile, the degree of explosive force, the facility of transport from the field of battle, and other circumstances differ; but the steady improvement in the results of abdomino-thoracic cases from year to year in the war of 1914-18 was a memorable triumph of surgery.

NON-PENETRATING INJURIES OF THE ABDOMINO-THORACIC ZONE

In contrast to the last great European conflict non-penetrating injuries of the abdomino-thoracic zone do not play the same small and infrequent part in war surgery to-day; the thoracic and abdominal viscera, solid and hollow, may be damaged under a variety of circumstances in "modern" warfare. Fragments or masses of timber, stone, or metal may be confusedly hurled with explosive force against chest and abdomen in the indiscriminate air bombardment of civilians; women and children have suffered "crush" contusions of thorax and belly from falling masonry and iron girders; visceral damage above and below the midriff may result from the blast of detonating bombs, mines, or other high-explosive machinery in close proximity to men and women of every age, condition, and calling, for in "total war" none can claim privilege or sanctuary. Nor does the diaphragm remain immune when chest and belly suffer violence.

Effects of Rupture of the Diaphragm

Rupture of the diaphragm may be produced by the passage of a heavy vehicle obliquely across the abdomino-thoracic zone, by the crushing force of buffer accidents, or from the demolition and collapse of buildings. An excellent account of the injury has been given by Gordon Bryan (1922), who points out that the lesion is not very rare in children and adolescents, whose chest wall is more elastic and can be compressed to a considerable degree without fracture. In some cases costo-chondral dislocations may occur, as shown by some displacement of the

chest wall and a clicking sound on respiration; at other times the diaphragm is torn by stretching or bursting, or may be lacerated by a fractured rib.

The convexity of the diaphragm is the part that usually suffers; on the rarest occasion the crus is damaged. The left side of the midriff is that most prone to rupture under such conditions of violence; the liver is more likely to bear the brunt of an injury due to compression of the right side, yet the right dome of the diaphragm has been torn, with a resultant haemothorax and even the escape of bile into the pleura. The diaphragmatic lesion may readily be overlooked in the presence of cataclysmic intraperitoneal bleeding. Rupture of the diaphragm produces shock, dyspnoea, and a disordered action of the heart. The pulse is rapid and irregular; the breathing is almost entirely thoracic, but diaphragmatic respiration may be restored after a day or two by the plugging of the rent by omentum, spleen, etc.

Dyspnoea and tachycardia occur with herniation of the stomach into the chest; and severe pain with rigidity of the left hypochondrium is complained of, and also pain in the neck or shoulder from irritation of the diaphragmatic peritoneum. Thoracic distress is produced after meals; radiological examination will readily establish the diagnosis.

Rupture of one or both crura of the diaphragm may occur as the result of a subparietal injury. Bryan (1922) records a rupture of the left crus associated with a compression fracture of the eleventh and twelfth thoracic vertebrae resulting from a fall of thirty feet on to the pavement in a sitting posture. The intraperitoneal haemorrhage, which suggested a ruptured abdominal viscus, determined a laparotomy.

Severe crushing injuries of the chest have been known to produce a *tearing lesion of the mediastinum*, even when there has been no fracture of ribs or sternum. This has been found associated with a large retroperitoneal haematoma from damaged vessels in the root of the mesentery (Sauerbruch and O'Shaughnessy, 1937). The displacement of the mediastinum may suggest the diagnosis of a tension pneumothorax; investigation of the intrapleural pressure and the use of radiography should prevent unnecessary and harmful surgery.

The diagnosis and treatment of *subparietal injuries of the spleen* are well established and require no comment. For similar *hepatic injuries* thorough surgical exposure is necessary. Subparietal or non-penetrating *injuries of the kidney* are generally isolated lesions, and most often are mere contusions of the organ without rupture of the renal capsule. In injuries of the abdomino-thoracic zone which menace life concomitant damage rather than the renal lesion demands most attention. The chief indications for early surgical intervention on the kidney are: (1) cataclysmic haemorrhage; (2) persistent pain and aggravation of the clinical symptoms and signs of renal injury during the first forty-eight hours, especially increasing tenderness in the iliac fossa and hypogastrium with spasm of the psoas muscle; such clinical phenomena denote a spreading extravasation of blood, urine, or both. The size of any perinephric swelling that may be detected is some criterion of the degree of kidney injury. An appeal may also be made to urographic methods of diagnosis.

It should be remembered that early exploration in a doubtful case will render this service to surgeon and patient—that a deliberate conservative resection of the damaged portion of the kidney can be considered at a period when urgency is not so extreme that only a hurried total nephrectomy can save life. In arriving at a decision as to the exact technique to be employed in a case, it behoves the surgeon to remember the slogan: "First save the patient, and secondly, if possible, save the kidney."

Sequelae of Rupture of the Diaphragm

Other effects of injury of the diaphragm include: (1) the lodgment of fragments of foreign bodies in the diaphragm itself; (2) diaphragmatic hernia; (3) scarring and adhesions.

The most dramatic of these sequelae is *diaphragmatic hernia*; this may develop immediately or soon after the injury; on the other hand symptoms are commonly delayed for several months or longer. Traumatic diaphragmatic hernia rarely produces symptoms on the right side, and at most contains only a small piece of omentum in that situation. Only very rarely does a rent occur between the abdomen and the pericardium. The left dome is that most often implicated, and the herniated viscera include the omentum, stomach, transverse colon and splenic flexure, spleen, and jejunum; it is stated that the pancreas, liver, and duodenum are only very rarely herniated.

Such cases are best operated upon by a thoracic approach: an incision is made in the eighth or ninth intercostal space; the resection of adjoining ribs may also be required. Positive-pressure anaesthesia is employed; the phrenic nerve is crushed as it lies upon the pericardium before entering the diaphragm. The extruded viscera are first separated from the edges of the diaphragmatic aperture and thoracic structures, and are then coaxed into the coelom.

The repair of the rent in the diaphragm may be difficult if the muscle has undergone fibrotic or atrophic changes. Strong silk is employed: in some cases fascial grafts seem to give greatest promise of permanent closure. In others the gap can only be closed by suture of the liver, spleen, or stomach to the margin of the opening. In cases of some duration the stomach may have undergone hypertrophy and dilatation, and a laparotomy may also be required to anchor it satisfacforily inside the abdomen. The performance of a temporary gastrostomy in some such cases has proved of inestimable value in my hands. The complication of *strangulation* in connexion with a *diaphragmatic hernia* is fraught with the gravest peril. The colon is the segment of the alimentary canal most frequently obstructed; sometimes the jejunum is the part compressed; very rarely is the stomach strangled.

A correct diagnosis is not often attained unless there is previous knowledge of the existence of a hernia; but where such knowledge is lacking an antecedent history of a severe injury in the abdomino-thoracic zone, a previous complaint of post-prandial discomfort and even dyspnoea, hiccup, precordial oppression, and pain in the shoulder, together with the evidence of competent radiology, should enable a pre-operative diagnosis to be made.

The symptoms of strangulation usually supervene suddenly; the baleful results of operation for this disastrous complication constitute a powerful argument for early operation upon traumatic diaphragmatic hernia, at any rate if the symptoms to which it gives rise show any evidence of worsening. The transthoracic approach should be employed.

Familiarity with the transdiaphragmatic approach to the vault of the abdominal cavity has been turned to useful purpose by thoracic surgeons in the operation of cardiomentopexy (O'Shaughnessy, J. B. Hunter). The successful operation by Pierre Duval (1918) for the extraction of a bullet from the suprahepatic portion of the inferior vena cava, in which the sternum was split and the diaphragm divided backwards to the caval opening still remains to my mind the most brilliant operation in the history of surgery.

Even the general surgeon avails himself of an abdomino-thoracic approach in operations for the surgical removal of

malignant disease of the lower end of the oesophagus or e cardiac orifice of the stomach.

No reference to the employment of the sulphonamide erivatives has been made in this communication; this is ow a routine measure, and its value is incontestable. The evere shock which appears so constant in wounds of the trunk in this war demands a bountiful supply of blood and plasma, which on occasion is preferably introduced rapidly into the veins of the recipent

In this war abdomino-thoracic injuries due to fragments of high explosive are probably less grave than those due to crushing force or the effects of blast.

PROTECTING MEDICAL SUPPLIES AGAINST CONTAMINATION BY GAS

The problem of protecting medical supplies against contamination by poison gas is analogous in many respects to that of protecting foodstuffs, and doctors and hospital authorities will therefore get much help from the handbook issued by the Ministry of Food, *Food and its Protection against Poison Gas*. Some medical supplies, however, present special problems of protection and decontamination and the Ministry of Health's circular (No. 2385) to local authorities and hospitals contains the following advice and suggestions.

The normal conditions of storage of medical and surgical supplies in suitably warmed and ventilated buildings should provide for most articles all that is practicable in the way of protection against liquid contamination. Some additional protection can also be afforded by using existing stocks of waterproof sheeting, batiste, cellophane, or other impermeable material if they are not required for immediate use as a covering for unprotected stores or stores whose nature or wrapping does not of itself provide protection.

Surgical dressings, cotton-wool, bandages, etc., wrapped in paper, cardboard, or cartons.—These would not become contaminated by exposure to vapour providing the wrappings are undamaged. Traces of vapour can, if necessary, be removed from such materials by opening them out and airing for an hour or so in a clean, well-ventilated warm atmosphere. Sterilization might be undertaken where the means are available. If contaminated by liquid it is extremely doubtful whether any decontamination treatment would be satisfactory and destruction by burning may be unavoidable.

Drugs and medicines in metal containers.—If adequately sealed no contamination of the contents can occur. If contaminated by liquid the containers should be decontaminated by repeated swabbing with solvent such as paraffin, petrol, etc., and airing; the corks, etc., unless protected by metal or other seal, should be destroyed and replaced by new ones.

Rubber materials, surgeons' aprons, waterproof sheeting, hot-water bottles, etc.—Vapour contamination will, in general, not be serious and could be removed by airing. If contaminated by liquid, decontamination by immersion in boiling water for a period of one to three hours, depending on the thickness of the rubber, would be essential.

Gum elastic catheters, surgeons' gloves, fine rubber drain sheeting, etc.—The finest grades of rubber materials are unlikely to stand boiling, and if contaminated by liquid should be destroyed. Covering to prevent such contamination is therefore most desirable.

Wooden furniture, bedding, etc.—The decontamination treatment for such articles is detailed in *A.R.P. Handbook* No. 4. In the case of bedding in general and mattresses in particular treatment in a steam disinfector is the only practical process.

Metal instruments and utensils.—These, depending on their nature, can be decontaminated by immersion for thirty minutes in boiling water or repeated swabbing with solvent.

MEDICINAL HERBS IN WARTIME

The Minister of Health recently appointed an expert committee "to review the present and future requirements of vegetable drugs in the light of Empire consumption and trade, and facilities for cultivation within the Empire; to consider the steps which should be taken to secure organization of cultivation and collection; and to make recommendations to the Minister." This "Vegetable Drugs" Committee has now presented an interim report and recommendations. The report differentiates between two groups of drugs—a "long-term" and a "short-term" group.

Long-term Group of Drugs

It is unlikely that any long-term policy will materially affect the supply of these drugs during the present emergency, as the latent period between initiation of schemes and production for the market is so long. One primary essential for a long-term policy is an assured and steady market and remunerative prices for the producers within the Empire, particularly in respect of drugs requiring many years of experimental cultivation and considerable financial outlay before regular supplies can be available. The establishment of such stable conditions would probably necessitate (a) financial assistance to growers in the Colonies and Dominions over a period of years, and (b) protective tariffs against supplies from pre-war producing countries. The present difficult economic and political conditions and the impossibility of knowing or forecasting the economic circumstances and political considerations that may operate at the end of the war make it impracticable and inadvisable at the moment to formulate any proposals involving such questions. The committee strongly recommends that the position should be further considered as soon as possible after the end of the war.

Short-term Group

Here the position is quite different. Supplies can be rapidly created and producers can recoup themselves during the war. After the war stocks may come on the market from countries now cut off from international trade, which may create serious difficulties for growers in the United Kingdom who may have considerable stocks on hand at the cessation of hostilities. Therefore, so far as production in the United Kingdom is concerned, it is suggested that H.M. Government might consider safeguarding the position of persons who have undertaken the cultivation of drugs, in the same way as is being done in other branches of agriculture. It is hazardous to grow these plants in climates or soils whose suitability has not been clearly tested by experience, and it is preferable to expand production in areas where the plants are already grown and collected. Much could be achieved during the war by intensifying the collection of wild plants and developing the use of related species or substitutes

Production of Vegetable Drugs in the U.K.

The committee considers that attention should be concentrated on the following drugs.

Agar	Ergot	Psyllium
Dill	Male fern	Sphagnum moss
Belladonna (leaf and root)	Liquorice root	Stramonium
Irish moss	Hyoscyamus	Dandelion root
Colchicum	Peppermint	Valerian
Digitalis		

Arrangements have been made by the Ministry of Health for regular growers in the United Kingdom to extend the areas under cultivation of certain extremely important drugs, which with other steps taken to secure supplies, ensures that the wartime requirements of these are safeguarded.

The committee points out that while the development of organized collection of herbs growing wild is most valuable and should be encouraged, the *growing* of medicinal herbs is a highly specialized industry which is not without its dangers to the inexperienced and that therefore growing by amateurs is to be discouraged. Considerable experimental work is being done at research institutes and agricultural stations on strains, seed production, growing, and utilization of various drugs, the results of which may be important. Steps have already been taken to encourage methodical collection, proper drying (which is most important), and marketing of drugs growing wild in this country.

Cultivation, Collection, and Marketing

During 1940 the Ministry of Health was engaged in correspondence with amateur growers and collectors regarding cultivation, collection, and marketing of vegetable drugs, and held several conferences with trade representatives. The Department also sponsored, in co-operation with the Ministry of Agriculture and Fisheries and the Board of Education, a

Press notice regarding cultivation of a limited number of vegetable drugs. The outcome of this correspondence and consultation was an arrangement whereby private growers and collectors disposed of their crops through trade channels.

The stimulation of interest in the supply of vegetable drugs in the United Kingdom has been carried further by the Royal Botanic Gardens, Kew, working in co-operation with the National Federation of Women's Institutes, Boy Scouts and Girl Guides organizations, and the trade.

The Royal Botanic Gardens have arranged with the National Federation of Women's Institutes to organize the collection of ten essential or important herbs in each county, a total of thirty herbs throughout the country. The agricultural organizer of the Federation is issuing circulars of instructions, and articles will appear in the *Journal of Botany* at the collecting season. Arrangements were made during 1940 by the Department of Health for Scotland and the British Red Cross for organized collection of sphagnum moss, and it is hoped now to collect increasing quantities not only in Scotland but also in other parts of the United Kingdom. The sponsors of these schemes hope that the arrangements made will avoid the disappointment experienced in the last war when so much of the amateur effort was wasted owing to incorrect methods of collection and inadequate preparation for the market; and that they will add substantially to the quantities of essential vegetable drugs available. Miss Barbara Keen and Miss Jean Armstrong have written an illustrated booklet entitled *Herb Gathering*, which will shortly be published by Messrs. Brome and Schimmer, 4, Leather Market, S.E.1, at 9d. Attention is also drawn to Bulletin No. 121 of the Ministry of Agriculture, *Medicinal Herbs and their Cultivation* (H.M. Stationery Office, 6d.).

Production in the British Empire

The committee notes with satisfaction that during the past twelve months the Ministry of Health has received many inquiries, offers of help, and details of experimental work being carried out, from Canada, Australia, New Zealand, East Africa, India, and elsewhere. Some of this experimental work has already indicated possibilities of important alternative sources of supply for some drugs normally obtained from outside the Empire. Consideration was given to the production in respect of argol, agar, wood creosote, datura leaf, ephedra, liquorice root, santonin, and squill; and arrangements have been made for inquiries to be instituted by the Imperial Institute, the Colonial, Dominions, and India Offices. A comprehensive and valuable memorandum by M. Ashby, Ph.D., on "War Time Drug Supplies and Empire Production," was published in the *Bulletin of the Imperial Institute*, Vol. 39 (1941) No. 1.

A subcommittee has been set up at the Ministry of Health to act as a clearing centre for information and advice.

LEPROSY IN THE BRITISH EMPIRE

The annual meeting of the British Empire Leprosy Relief Association was held at the India Office under the chairmanship of Lord Lugard. Sir WILLIAM PEEL, chairman of the Executive Committee, said that owing to the war the projected tour of the medical secretary, Dr. E. Muir, to the West Indies and South America had been postponed, but a fortunate turn of events had now made it possible. The Government of Trinidad had requested the services of the Association in finding a suitable medical man to take charge of the leper asylum in that colony, and Dr. Muir had been accepted for the post on the understanding that his term of service would not exceed eighteen months, and that permission would be given to visit and report upon the position in respect of leprosy in certain other West Indian colonies and in other places. Sir William Peel went on to say that while the Association continued to carry on its work with a fair measure of success the great problem of leprosy still remained unsolved, and no marked reduction in the incidence of this terrible scourge had been effected. In many colonies there were other more lethal diseases the prevention and treatment of which taxed the financial resources to such an extent that leprosy had been forced into a secondary place.

Infection and Segregation

Sir LEONARD ROGERS, who serves as acting medical secretary in Dr. Muir's absence, said that epidemiological studies had revealed that 80% of infection arose in the households of leprosy cases, mostly through infection of children, and that nineteen out of every twenty infections were derived from prolonged contact with the much more infectious skin or lepromatous type, and only one from nerve cases. This had led to the release as uninfective of one-third of the cases segregated in South Africa. In a badly infected area in the Southern Sudan over half the 7,000 cases moved to large agricultural colonies had also been cleared of all symptoms of active disease. In Nigeria, the most seriously infected of our colonial possessions, within ten years the patients, mostly infectious, isolated and treated under a purely voluntary system in large agricultural colonies, had increased from 2,500 to nearly 7,000. Little progress had been made during the last few years in discovering a curative treatment for all stages of the disease, but a new oil, closely resembling hydnocarpus oil in its chemical formula, was now being tested, and it was on such chemotherapeutic lines that progress was most likely to be made.

In reply to Sir FRANCIS FREMANTLE, who asked whether the statement that there was no sign of lessened incidence of the disease was correct, the CHAIRMAN said that undoubtedly cases were cleared, but new cases came to light in equal number, and thus the incidence was maintained. The annual report adopted by the meeting showed that the number of workers actually in the field included four doctors, fourteen lay workers, and one nurse.

AWARDS FOR GALLANTRY IN CIVIL DEFENCE

The appointment of Mr. F. D. Murphy, F.R.C.S., senior resident surgeon, Fulham Hospital, to be an O.B.E. (Civil Division) is announced in a *Supplement* to the *London Gazette* dated May 30, 1941.

Mr. FRANCIS DOMINICK MURPHY: "When the Fulham Hospital suffered direct hits from high-explosive bombs, Mr. Murphy displayed marked efficiency and coolness and set a splendid example to the patients and the staff. In extremely difficult and dangerous conditions he personally directed the transfer and evacuation of patients and throughout showed courage and determination."

Dr. J. D. Dillon, medical officer in charge, Mobile Unit, Greenwich; Dr. D. Millar, medical practitioner, Glasgow; Dr. J. S. McL. Ord, police-surgeon, Glasgow City Police; Cecilia McGinty, district nurse, Glasgow; and Dr. H. Glyn-Jones, medical officer, American Mobile Unit, Lambeth, have been awarded the M.B.E. (Civil Division). The announcement in the *Supplement* to the *London Gazette* dated June 6, 1941, reads as follows:

Dr. JOHN DESMOND DILLON: "Dr. Dillon, during the whole period of his association with the casualty services, has rendered splendid service. On one occasion a casualty was trapped in the basement of a building the upper storey of which was blazing. Quite regardless of risk to himself, Dr. Dillon went down amidst the wreckage in order to extricate the casualty. Water heated by the fire was streaming down into the debris, but the doctor crawled through, reached a boy and administered morphine. Dr. Dillon was himself at the time of this incident a casualty, for earlier in the evening he had been injured when extinguishing an incendiary bomb."

Dr. DANIEL MILLAR, Dr. JOHN SMITH MCLAREN ORD, and CECILIA MCGINTY: "A tenement building was partly demolished by a high-explosive bomb. Rescue workers tunnelled through to a trapped person and Dr. Millar administered morphine to him. Dr. McLaren Ord arrived and it was decided to amputate the man's foot in order to release him. With Nurse McGinty the doctors entered the tunnel and Dr. Millar performed a forty-minute operation, the anaesthetic being given by Dr. McLaren Ord, assisted by Nurse McGinty. During the entire period the remaining part of the building was on the point of collapse and occasional falls of wreckage took place. By their gallant action, performed at great personal risk, the doctors and nurse succeeded in extricating the trapped man."

Dr. HAROLD GLYN-JONES: "A bomb demolished a large building and the occupants were trapped. Every service combined to extricate the victims, and the driving of tunnels into the shaky mass of masonry and girders led to the rescue alive of many casualties. Throughout the rescue period of nine hours Dr. Glyn-Jones was indefatigable. At much personal risk he crawled down tunnels to give morphine and temporary treatment to the wounded, and his courage and determination were alike outstanding. He received the greatest help from Wilfred John Clarke, sergeant, A.R.P. Stretcher Party, Lambeth (awarded the British Empire Medal (Civil Division)), and Norman Jaeger, leader, A.R.P. Stretcher Party, Lambeth (awarded a bar to the British Empire Medal (Civil Division)), whose fearlessness, like that of the doctor, was a conspicuous example to others. The efforts of Dr. Glyn-Jones and of the two stretcher-bearers were instrumental in saving many lives."

Local News

ENGLAND AND WALES

The Red Cross and the Civilian Population

The civilian injured by enemy action is now, as the soldier has long been, the recipient of Red Cross help. This extension of the work of the Red Cross was brought to notice in a paper read before the Royal Society of Arts by Major-General Sir John Kennedy, vice-chairman of the executive committee of the British Red Cross and St. John War Organization. At the time of the Battle for Britain last autumn while the Government and local authorities were organizing machinery to relieve civilian distress, the Red Cross, he said felt it its duty to come to the immediate aid of civilians A sum of a quarter of a million was placed at the instant call of the officers of the organization in the various counties, and they were told to use it without undue formalities to meet the immediate needs of those who had suffered Special services included the giving of information to relatives and arrangements for the latter to visit the patients in hospital : the commissioning of a fleet of 170 ambulances for use particularly in air raids, in addition to the 200 Red Cross ambulances already attached to the Home Commands : and the admission of civilian as well as Service convalescents to the auxiliary hospitals and convalescent homes which have been established in this country with accommodation for 20,000 beds. Another phase of Red Cross activity is of enormous importance in fortifying civilian morale In this war members of detachments of the British Red Cross and the Order of St. John numbering some 300,000 have been called upon to volunteer for other duties than hospital service As fully trained men and women they entered the A R P services, which then consisted mostly of volunteers who were unqualified and inexperienced, though eager and willing enough. In doing so these Red Cross workers relinquished their distinctive designation, exchanging their more famous emblem for the A.R.P. badge. "One reads of the exploits of the A.R.P. services," said Sir John Kennedy "but it is only we who know from the reports which we receive how much of the credit could rightly be claimed by detachments of the British Red Cross Society and the Order of St John These men and women have manned first-aid posts, formed the crews of mobile units, served as stretcher-bearers, driven ambulances, staffed rest centres, rescued wounded and injured and aided doctors in emergency treatment, all in the midst of the fiercest assaults to which the population of this country has ever been subjected.

Medical Sickness and Life Assurance

The annual general meeting of the Medical Sickness, Annuity and Life Assurance Society, Ltd., was held in London on May 5, with Dr. F. C. Martley in the chair. In moving the adoption of the accounts Dr. Martley said that the head office had been destroyed by enemy action, but there were no casualties among the staff and the records had already been removed to the society's registered office at Highfield, Chesterton, Cirencester. New business during the year had been at about 40% of the pre-war figures. In both the life and the sickness departments the claims were heavier, due in the former to war claims and in the latter to the serious epidemic of influenza in the early part of 1940. A further £50,000 had been transferred to the War Emergency Reserve Fund, making the total £150,000, which it was hoped would suffice to provide for the heavy fall in the value of assets. All surplus moneys went into British Government securities, the holding in which had been increased to £387,366. The quinquennial valuation was due at the end of 1941, and while hopeful of satisfactory results, he must utter a word of warning to members not to be too-hopeful of bonuses. All resources must be conserved to meet the commitments and liabilities in view of the uncertain condition of affairs in the world in general. A recommendation of the Board was adopted to the effect that no interim bonus be paid on with-profit policies for permanent sickness and accident insurance and life assurances for the year 1941, but that interim bonuses for the years 1937, 1938, and 1939 be paid on all such policies becoming claims during 1941. The report of the directors stated that the new sums assured in the Life Assurance Fund totalled £154,290, with an annual premium income of £4,015. The claims paid were £42,647. Premium income amounted to £147,051, and the rate of interest earned on this fund was £3 5s. 3d.% after deduction of tax. The new annual premiums in the Sickness Fund totalled £4,575, and £67,895 was paid in claims : the premium income amounted to £129,910, and the rate of interest earned was £3 6s 9d.%, again after deduction of tax The total funds now amounted to £2,181,752.

CANADA

Scientific Research in Canada

Lieut.-General A. G. L. McNaughton, general officer commanding the 1st Canadian Corps Overseas Force, is also president of the National Research Council of Canada, and in the latter capacity gave an address before the Royal Society of Arts on May 13 on the subject of research in the Dominion. The organization of research in Canada as a function of government dates back to the last war, when the example of the home country was followed and an advisory council for scientific and industrial research was established. It was not contemplated at that time, said General McNaughton, that the council would establish laboratories of its own ; it was to act as an agency for consultation and co-ordination between those already carrying on research in the existing laboratories of the several departments of the Dominion and Provincial Governments, of the universities, and of industry. By 1932, however, the council, now the National Research Council, had its own laboratories, and in 1939 its annual budget was one million dollars. In Canadian industry there were, on the eve of the present war, over 1,000 laboratories with 2,500 full-time professional workers The council has developed close relations with every branch of science in Canada, with the universities, with the Government Departments concerned with research problems, and with the great professional societies in medicine and other fields. General McNaughton mentioned a few fields of research to illustrate the wide range of work carried on, especially in agriculture and forestry, and in chemistry, physics, and engineering A system of assisted researches has been instituted whereby professors in charge of university departments may be given financial assistance for the provision of needed apparatus and laboratory help. No attempt has been made by the council to monopolize research, in fact it has encouraged research in the universities and elsewhere Much work has been done through associate committees, which direct co-operative research on the problems assigned to them. One such committee is on aviation medicine. This was under the chairmanship of the late Sir Frederick Banting and it was while carrying out the very important programme of work planned by this committee that Sir Frederick Banting lost his life in a flying accident. The loss of such a great leader in this and other important research work is greatly mourned in Canada and in scientific circles all over the world, but his work, said General McNaughton, would live, as his committee would see to it that the many projects he initiated would be continued. General McNaughton added that all this research work in Canada was going forward in closest consultation with the authorities in Great Britain and with their mutual friends and colleagues in the United States.

Canadian Blood Serum for Britain

Blood serum, prepared at Toronto University in a laboratory equipped and financed by the Canadian Government, is to be shipped to Great Britain for use in the treatment of air-raid casualties. The serum, prepared from the blood of voluntary donors, was first distributed to the Canadian Forces in Canada and the United Kingdom, but the Department of Pensions and National Health, in agreement with the Department of National Defence, recently informed Mr. Malcolm MacDonald, United Kingdom High Commissioner in Canada, that they were able, if desired, to begin shipments as a gift to the United Kingdom Government. This offer has been accepted with gratitude, and 500 bottles of serum, each sufficient for one administration, are to be sent to the National Institute for Medical Research, London. It may be possible to arrange for small shipments by air. Mr. MacDonald has been asked to convey to the Canadian Government the cordial appreciation of the United Kingdom authorities.

Reports of Societies

TRAUMATIC SHOCK

At a meeting of the Manchester Pathological Society held in the Medical School on May 14, with the president, Dr. A. HILLYARD HOLMES, in the chair, Prof. J. H. DIBLE gave a lecture on "Some Aspects of Traumatic Shock."

Prof. Dible, who defined shock as a condition of low blood volume, discussed the lines along which the present position of our knowledge of shock had been reached. He outlined the historical development of our knowledge, and the theories which had been propounded during the last war, leading up to the traumatic toxaemia theory of Bayliss and Cannon and the view that the active substance might be histamine. He reviewed the work of Blalock, Simonart, Macdonald and Holt, and O'Shaughnessy and Slome, and the evidence which stressed the importance of the local effusion in the genesis of shock. The influence of the nervous system and that of the suprarenal cortex were also discussed. On the clinical side, the differentiation of various factors which contributed to the condition of low blood volume was considered and the findings described in examples of the different types.

Finally, the syndrome recently described by Bywaters and Beall and others[1] in which anuria and uraemia follow crush injuries with recovery from the immediate shock was discussed at some length. The anatomical changes in the kidney were described and the similarity of the picture to that seen in other examples of intense intravascular haemolysis, such as blackwater fever and incompatible blood transfusion, was emphasized. Prof. Dible expressed the opinion that the important renal change was one of intense catarrh affecting the whole nephron and leading to an excessive filtration and reabsorption of the glomerular filtrate. The pigment in the urine in this condition did not appear to be haemoglobin; there was, however, extensive muscular necrosis, and recent work at the British Postgraduate Medical School has adduced evidence that it was myohaemoglobin.

Correspondence

Relationship of Patient and Doctor

SIR,—May I stress—in a different connexion, and especially for the consideration of the Medical Planning Commission—two clauses in the summary and conclusions of the Goulstonian Lectures (*Journal*, June 7, p. 850). Dr. Paul Wood there says that treatment of Da Costa's syndrome in the Army is shackled "by the difficulty in establishing intimate contact with a patient who did not choose his medical confidant" and "by the duty of having to serve the State first, the patient second." He thus illustrates and confirms the importance of two essentials of a general practitioner medical service as they have been stated in B.M.A. policy—free choice of doctor and the preservation of the relationship of doctor to patient as prime and predominant, not subordinated to any other. Both these essentials have been disputed, and each has sometimes been injudiciously defended. There are, no doubt, many cases of individual illness in which free choice of doctor is unimportant as regards recovery; and it is both unnecessary and untrue to depreciate the work of salaried medical officers owing loyalty to councils, committees, or superior officers. But broadly, as principles underlying any general medical service for the nation, the immense value of these two factors cannot properly be disputed unless all experience and tradition of medical practice are found to be false.—I am, etc.,

Mudford, Yeovil, June 7. HENRY B. BRACKENBURY.

Ship Surgeons and the Medical Personnel on Military Transports

SIR,—This, I hope, is not an inopportune time to draw attention to the position which ship surgeons hold in the passenger ships which have been taken over and are now used as H.M. Transports.

Ship surgeons are engaged by the shipping company and are approved by the Board of Trade, and they normally enjoy in the ship and amongst the passengers a status and position second to no one on the ship's staff. But since the vessels have been put into service as military transports his status on these boats tends to become secondary and subsidiary, and from being in a position of trust and confidence responsible for the health and welfare of all on board, the ship surgeon now finds himself relegated to a narrow sphere, where he is permitted, as it were by an act of grace, to carry on. This limitation of his activities is due to the attitude of those who frame the regulations governing sea transport and who, with very little regard for the attainments, rights, and duties of the ship surgeon, transfer to the Service medical officers the charge of everything connected with the health of the vessel.

Let me quote from Voyage Regulations, 1935 (published 1940), para. 201, page 54: "The S.M.O. will take sanitary and medical charge of the ship and crew, and will frequently inspect the quarters occupied by the crew, and will frequently call the attention of the Master and the O.C. troops to any neglect of sanitation." There is little need to comment on this; it leaves no room for ambiguity or doubt, and all the subsequent paragraphs defining the duties of the S.M.O. equally ignore the position of the ship surgeon, with the exception of one significant paragraph, to which I shall presently refer.

Here I may say a word about the appointment of the senior medical officer. Sometimes he is chosen from the medical officers who are travelling with their units, and with these men I am glad to say my relations have always been cordial. At other times—and this is now becoming the established custom—an S.M.O. and assistant M.O. are appointed permanently or semi-permanently to the larger ships. It is usually here that the points of conflict arise. He has official sanction for the view that he supersedes the ship surgeon, who like some obscure star dances round the more majestic orb. I shall cite from my own experiences some of the unhappy consequences accruing.

I did a long journey to the Far East with a gentleman who was benevolent enough to inform me that I should be "allowed to look after the crew." And when a member of the crew died he ordered me, as my "superior officer," to change the diagnosis I had entered in a ship's official document from "heat exhaustion" to "heat stroke." Incidentally, he had not seen the patient; he had never seen a case of heat stroke; I had seen several. And the document in question did not concern him in any way.

This may seem an example of an extreme case, but I have heard of instances of tactlessness and aggression equally unfortunate. Such a state of things is hardly tolerable; it is unfair to a man in his own ship. And while the existing regulations stand, with all the emphasis in the interests of one party, difficulties are constantly liable to arise, and only the exercise of great patience can ensure that the relationships shall be tolerably friendly.

Perhaps it would not be out of place to make a few comments on the status of the S.M.O. in his relations with his brother officers on board. If he is the type who likes to assert his authority by taking control of their patients, his relations with the various medical officers in charge of the units are not likely to be happy. It is a bad arrangement on both sides. And if he finds himself in contact with a homogeneous unit such as a field ambulance, these specially selected men are not likely to be passive under the struttings of a person who is in every way their intellectual inferior. And as to his relationship with colonial troops and doctors—well, it is a point that I need not labour. Such things I have seen and observed.

Finally, may I be permitted to question the wisdom of keeping two military medical men permanently on board the larger ships and one on the smaller vessels, numbers which amount to a very large total in the aggregate, at a time when at home, in London and the Midland cities, there is a crying need for doctors. Several of the S.M.O.s with whom I have spoken share this opinion very emphatically; they feel that their services are superfluous, to say the least of it.

I shall now quote para. 220, page 58, from the Voyage Regulations to which I have already referred: "If, owing to exceptional circumstances, there is no military medical officer on board a transport or freightship, military passengers will be warned that, except in cases of voluntary passengers will inoculation of officers and their families, no fees whatever should be paid for attendance by the civilian ship surgeon." "Warned," I take it, against the dishonesty and cupidity of the ship surgeon, who is apparently liable to importune for

fees, in spite of the fact that when he assumes charge of military personnel full instructions are handed to him regarding the scale of remuneration and the submission of his claim for payment—instructions which leave no room for ambiguity or doubt. When first I heard of this "warning" from some officers I thought they spoke in jest; that they were leg-pulling, in fact. I do hope that something more expressive of an arrangement between gentlemen will soon take the place of this tendentious paragraph.

I have touched on some of the disadvantages under which the ship surgeon now labours. But it ought not to be beyond the wit of man to devise some arrangements which would recognize his position and status, acknowledge his usefulness, and make a proper employment of his services. At present he is merely the crew's doctor, with duties that are trifling. It tends to be a dull life, and all the praises poured forth on the air about the self-sacrifice of seafaring men, though gratifying, do not quite make up for it. In addition to this he has suffered a considerable diminution in income since the cessation of the passenger traffic—a matter of no light moment in many cases.

In this account I hope I have not been over-critical or censorious. It has only been my intention to point out some very real grievances, and I do so all the more willingly as I am only temporarily a ship surgeon and I feel therefore that I can speak disinterestedly on behalf of a large body of men who are not obtrusive or clamorous in their claims but who wish to be allowed to maintain their self-respect on their ships, and who ought not to be impeded, harassed, or penalized in any unnecessary or gratuitous manner.

Should this letter evoke any correspondence I am afraid that I shall not see it for some four or five months.—I am etc.

JAMES PRENDERGAST
Ship Surgeon.

Liverpool, May 15.

Undergraduates Training in the Municipal Hospitals

SIR,—The correspondence in recent issues of the *Journal* gives a very inadequate picture of the extent to which facilities for undergraduate teaching were provided in the L.C.C. hospitals before September, 1939.

(1) Arrangements made with the deans of the several medical school hospitals in London were in operation for some years prior to 1939 for the provision of facilities for medical students from every one of the medical schools to be attached to one or more L.C.C. hospitals for their midwifery work. It is no exaggeration to say that had it not been for the facilities provided at L.C.C. hospitals it would have been impossible for London medical students to comply with the requirements of the General Medical Council.

(2) Similarly arrangements were in operation for some years by which every medical school hospital was attached, for the purposes of clinical instruction at the bedside, to one or more L.C.C. hospitals. This meant that on one or more afternoons each week from each medical school a group of medical students selected by their own teachers went to an L.C.C. hospital and there saw patients specially chosen for the demonstration and were taught by their own teachers.

(3) Arrangements were also made for the provision of teaching facilities at some of the L.C.C. special hospitals, notably at St. Margaret's Hospital, North St. Pancras—the only hospital in London where it was possible to teach not only medical students, but also graduates, certificated midwives and pupil midwives, all about ophthalmia neonatorum—quite one of the rarest diseases to be seen nowadays in any other London hospital. If it were not for St. Margaret's Hospital practically every medical student and every pupil midwife in London would go into practice without ever seeing a case of ophthalmia neonatorum and how to treat it.

(4) It is unnecessary to dwell upon the facilities provided at the L.C.C. fever hospitals because they are well known to everyone, but it is not so well known that at L.C.C. hospitals there were in peacetime by far the most extensive series of specialized "units" to be found anywhere in this country—for example, fractures of all kinds, plastic surgery, thoracic surgery, thyroid disease, poliomyelitis, encephalitis, pernicious anæmia, epilepsy, congenital syphilis, orthopaedic cases, etc., etc.—but unfortunately little advantage was taken of the marvellous opportunities available at these specialized units for undergraduate or postgraduate study.

It remains for me to add that in actual practice, though all these advantages for the teaching of the medical student were freely available and largely taken advantage of by the deans of the medical schools, there was one outstanding practical difficulty which we had not quite overcome but which I am sure could and should be overcome when war is over and we are able once more to turn our attention to the training of the medical student and many other allied problems. The difficulty was that as a rule the staff of the medical school hospital quite naturally wanted to teach their own students at the L.C.C. hospitals. No great objection was taken to this procedure by the L.C.C. hospital staff, although it is obvious on the face of it that the teachers from the medical schools could not teach properly on patients they knew very little about and furthermore it was not easy always to avoid saying something at the bedside which the patient might interpret as a criticism, quite unintentional, of the diagnosis and treatment by the L.C.C. medical officer in charge of the case. Much more could be said on this difficulty but space will not permit, and therefore I content myself with the suggestion that one way of overcoming this difficulty is for an arrangement to be made in future whereby the teaching staff of the medical school hospital attached to an L.C.C. hospital or hospitals, should become the consultant staff of the L.C.C. hospital. This would enable the staff of the medical school hospital and L.C.C. hospital to work together in still greater and more harmonious co-operation and for the medical school teacher to be thoroughly familiar with the clinical condition of the patients upon whom he proposes to teach. The other alternative, and one which could often be adopted, would be for the medical student when visiting an L.C.C. hospital to be taught by the L.C.C. medical officer and for that officer (or officers) to become an honorary member of the medical school teaching staff. Possibly a combination of both schemes would be best of all. In certain of the L.C.C. special hospitals or specialized units the only possible teacher would be the L.C.C. medical officer.—I am, etc.

FREDERICK MENZIES.

Criccieth, June 1

Cut Flexor Tendons

SIR,—In your issue of March 15 (p. 417) Mr. H. Blacow Yates advised amputation as the best means of securing an early return to work in cases of flexor tendons which have been divided within their digital synovial sheaths and in which a rapid recovery is of national importance.

It is admitted that the suture operations, whether primary or delayed, as at present practised rarely restore normal function. Nevertheless, I submit that some of these urgent cases for which amputation is recommended would be better-treated by a deliberate fixation of the tendon to the digital sheath provided that the degree of permanent flexion of the interphalangeal joints obtained permits of satisfactory opposition to the thumb, and that the scar is lateral so as to avoid trouble from pressure. Many cases in which suture has been attempted are discharged with a stiff but useful finger if flexed at these joints, and with less disability than if amputation had been done. There are some occupations in which a fixed flexed finger would prove a severe handicap, and in these primary amputation is the best procedure. Of course, in the case of the thumb conservative measures are almost always preferable to amputation.

Concerning the level at which amputation of the fingers should be performed for lesions of the flexor profundus tendon, this should be just proximal to the distal interphalangeal joint, and the resulting disability is only slight.

For lesions affecting both deep and superficial tendons the level will depend on the finger involved. In the case of the index the whole finger should be removed and, preferably, in addition an oblique portion of the metacarpal. Dr. H. A. Haxton, on the same page of the *Journal*, referred to the advantages of such a procedure: the patient rarely uses the stump consisting of the first phalanx, if remined, but prefers to employ the middle finger instead and not infrequently finds the stump a nuisance. For the middle and ring fingers it is advisable to amputate through the head of the first phalanx, as the stump not only adds to the strength of the grip but also prevents deviation of the adjacent fingers. The loss of the little finger is not serious, but when strength rather than appearance is the object it is better to amputate through the head of the first phalanx; otherwise the procedure should be as for the index.

It should be possible to evolve a technique for suture within the flexor sheath and after treatment to produce a high percentage of successful results, and Mr. Blacow Yates has done a valuable service in directing attention to the present unsatisfactory position, especially as this leads to so great a loss of valuable time.—I am, etc.

PHILIP HAWE, Ch.M., F.R.C.S.,
Lieut.-Colonel R.A.M.C.

Treatment of Injuries of the Fingers

SIR,—From time immemorial medical students have been taught that when dealing with injuries of the fingers their watchword must be "Save all you can," and this advice lingers, copied from paper to paper and textbook to textbook. Quite recently no less distinguished a surgeon than Sir John Fraser has given his authority to this fallacious teaching in a memorandum circulated by the Department of Health for Scotland. Sir John dismisses the subject of amputations of the fingers with the advice that "the utmost conservatism must be exercised; a functioning digit or any portion of it should be preserved if possible." Blind adherence to this policy of undiscriminating conservatism has condemned untold numbers of patients to months of painful dressings and disability and to repeated operations in a useless endeavour to save part of a finger which should have been amputated at the start.

In the *Journal* of March 15 (p. 417) you published two letters in which the policy of conservatism was challenged: Dr. H. A. Haxton questioned the value of a short index stump and advised amputation through the shaft of the metacarpal; Mr. H. Blacow Yates questioned the efficacy of suture of the flexor tendons within their digital sheaths and suggested that a primary amputation would be better treatment. I have expected each week to read an angry reply to these heresies, but as none has appeared I am emboldened to suggest that there are many other indications for radical treatment in dealing with finger injuries.

Every bit of the thumb is valuable and none may be sacrificed, but in the case of the fingers it is unfair to the patient to attempt to save, or to continue conservative treatment of, a finger which is doomed to be permanently stiff, useless, or painful. Immediate amputation is therefore indicated in the following circumstances: (1) Crushed fingers in which the finger-tip is ischaemic. (2) Compound fractures of the middle or proximal phalanges in association with severed tendons. (3) Comminuted fractures of two phalanges with a shattered joint between them. (4) Compound fractures of terminal phalanx involving the joint. (5) Finger wounds with extensive skin loss. These injuries almost always result in stiff useless fingers. Only if several fingers are involved is it worth while attempting to avoid amputation by the immediate application of skin grafts. (6) The finger ankylosed in extension is a nuisance to the patient and a reproach to the surgeon; no time should be wasted before removing it. (7) Division of the flexor tendons within their digital sheaths. Like Mr. Blacow Yates, I have never seen a good result following suture, and consider that immediate amputation is the best treatment.

In determining the level of amputation the following points should be remembered:

(1) The bone end must be covered with good skin and without tension.

(2) The scar should not be terminal and should not be on the palmar surface unless this is absolutely unavoidable.

(3) The loss of part or all of the terminal phalanx is no handicap, except in certain special occupations.

(4) The amputation of all or part of the proximal or middle phalanx of the index finger leaves a stump which is a nuisance. If amputation higher than the terminal phalanx is necessary it is better to sacrifice the whole finger and make the amputation obliquely through the metacarpal shaft.

(5) Amputations through the proximal or middle phalanges of the middle or ring fingers leave stumps which usually are useful.

(6) Amputations proximal to the web of a finger or disarticulations at the metacarpo-phalangeal joint should be avoided; they leave ugly stumps which get in the way and the fingers on either side become adducted. Instead, amputate about 3/4-inch proximal to the joint, through the shaft of the metacarpal.

(7) Loss of part or all of the little finger causes but slight disability. Unless all or the greater part of the middle phalanx can be retained it is better to amputate obliquely through the shaft of the metacarpal.

These "rules" are based on personal experience and observation. They are brought forward in the hope that they may stimulate discussion on the very important but neglected problem of finger injuries. Out of the experience of surgeons who have seen a large number of these cases, and from the records of insurance companies, it should be possible to formulate a set of rules that would be generally acceptable.—I am, etc.,

J. B. OLDHAM.

May 30.

Treatment of Osteomyelitis

SIR,—Chronic osteomyelitis will, I believe, prove to be one of the most serious surgical problems of the war, for at least two reasons; first, it is a common result of gunshot wounds of bone; and, secondly, we do not appear to have made much progress in the treatment of this condition. Cases are still attending hospitals for dressing and occasional scraping of sinuses resulting from wounds of the last war; twenty-five years of dressings is not a unique history. Chemotherapy does little to help, which is what one would expect. The avascular nature of the lesion makes it unlikely that drugs will reach the focus even if they were likely to be useful there.

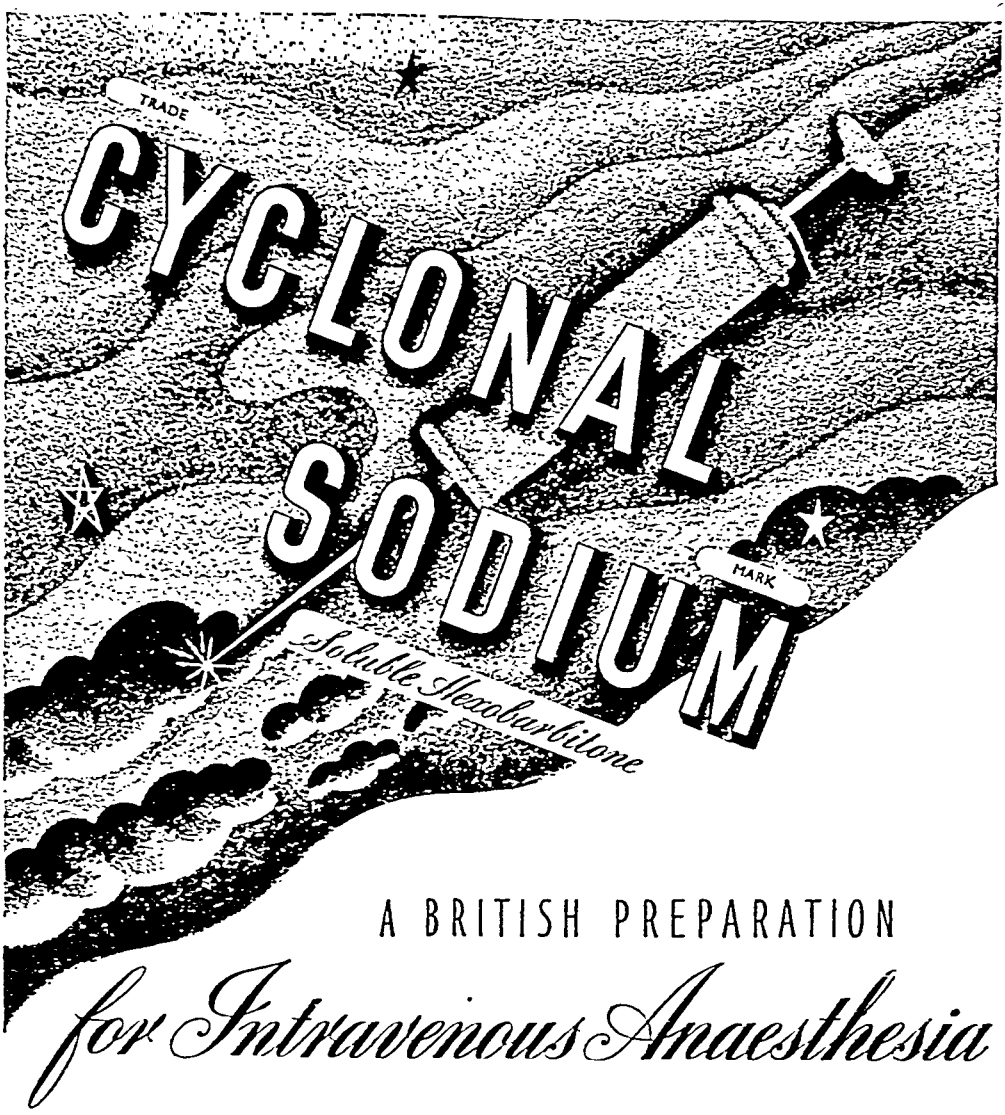
The treatment of acute osteomyelitis has ranged from gutter-ing to the extremes of diaphysectomy on the one hand and to drill holes on the other. Closed-plaster methods have helped greatly in the acute condition, but do any of these methods prevent the condition passing into the chronic phase? If the infected bone is in such a position that a shallow saucer-like depression can be cut out of the bone and the space so formed filled with a muscle-graft, healing may be permanent, but take a by no means uncommon case—chronic osteomyelitis of the lower end of the femur without sequestrum formation: what can one do for this condition? I have known such a condition remain healed and apparently cured for seven years, and then the disease break out so violently with two pathological fractures that amputation at the hip-joint had to be performed as a life-saving operation. Would a patient with chronic osteomyelitis of the lower end of the femur be better off with an amputation and an artificial leg?

My real objects in writing this letter are three: (1) To remind us all of this problem and to bring it especially to the notice of those on the threshold of their surgical career. (2) To gain what information I can regarding the progress of treatment of this malady. (3) Most important of all—to plead for some centre or colony for pensioners whose wounds have produced this condition, where a concentration of thought and effort for this particular purpose would be available, and where the degenerative and depressing effects of chronic invalidism could be mitigated by occupation and industry suitable to the disabilities of the workers, as has been done in other conditions—e.g., at Papworth. Now is the time to start such a scheme if "planning ahead" is no idle phrase.—I am, etc.,

H. J. MCCURRICH.

Hove, June 2.

Obscure Nervous Effects of Air Raids



SIR,—Mr. Tom Harrisson's second letter (May 31, p. 832) prompts me to venture on a disclaimer. The aetiology I suggested in my letter of April 26 (p. 647) was intended to apply to a specific syndrome, as I understand it from the original description. I agree with Mr. Harrisson that there is throughout the profession a "tendency to gloss over the serious psychological effects that air raids have on people," and to insist that the neurotic effects are negligible." I would be sorry if Mr. Harrisson imputed this tendency to me.—I am, etc.,

H. CRICHTON-MILLER.

London, W.1, June 1.

"Egyptian Tummy"

SIR,—From my experience in Egypt for four years, including the summers, I, with others, suffered from this really trouble-some disease. It occurred in the hot weather as well as at other times, and in common with others, I attributed it to food infection, as it recurred in many people and as no one could be sure of the food they consumed. I can only say that, while chill may conceivably aggravate it, in the main it could not be the cause of those violent attacks of vomiting.

A BRITISH PREPARATION

for Intravenous Anaesthesia

Supplied in *Boxes of 6 x 0.50 Gm. ampoules with 6 ampoules distilled water.*

Boxes of 6 x 1 Gm. ampoules with 6 ampoules distilled water.

Boxes of 25 x 1 Gm. ampoules with 25 ampoules distilled water.

VITAMIN THERAPY

THE PROTECTIVE FACTORS IN PREGNANCY AND LACTATION

Even under the most favourable circumstances, pregnancy, labour and lactation make considerable demands on the mother. Ante-natal care has, therefore, the dual object of preventing the disorders to which she is especially prone and of building up the reserves of the healthy body by advising her about her diet. Although we know that the quantity of food need not be increased, the qualitative requirements rise considerably in the case of some of the protective factors.

RECTIFYING THE DEFICIENCIES

Surveys made within recent years have shown the great prevalence in the ordinary diet of deficiencies of most of the vitamins as well as of calcium and iron. Expectant and lactating mothers are, therefore, particularly liable to suffer; and the effects, sometimes latent in them, will be reflected in their infants.

Pregnavite affords the most convenient and economical means of supplementing the pregnancy diet with vitamins and mineral salts (*see table below*). Its wide range of protective factors makes it the best means of increasing the mother's reserves.

PERFECTING THE BREAST MILK

A satisfactory flow of breast milk is of the first importance, but where the mother's diet is low in protective factors the milk is low in them also. Additional cow's milk, which is widely relied upon, supplies vitamin A and calcium satisfactorily. It is, however, poor in iron, vitamin B and vitamin C. A deficiency of vitamin B_1 in the breast milk results in poor appetite in the infant and opens the way to a series of digestive disturbances. The breast-fed baby also often relies entirely on its mother for vitamin C, for which she has been accustomed to taking fruit.

Enriching the mother's diet with vitamin B_1 and vitamin C is rapidly followed by an increase of these factors in the milk.

Pregnavite in recommended doses supplies :—

VITAMIN A ..	4,000 i.u.	CALCIUM ..	350 mg.
VITAMIN B_1 ..	200 i.u.		
VITAMIN C ..	400 i.u.	PHOSPHORUS ..	550 mg.
VITAMIN D ..	300 i.u.		
VITAMIN E ..	2 mg.	AVAILABLE IRON	12 mg.

PREVENTING ABORTION

The use of wheat germ oil in the treatment of cases of sterility and habitual abortion of dietary origin is the result of research extending from 1920 until the present day. The treatment, according to published reports, has been successful in about 70 per cent. of cases. The classical experiments were all carried out using *whole* wheat germ oil.

Whole wheat germ oil has been available since 1934 as Fertilol, which is a highly active *natural and stable* source of vitamin E, plus the other naturally occurring factors of wheat germ oil.

ESTABLISHING LACTATION

Where there has been previous difficulty in establishing lactation Bemax taken throughout the later months of pregnancy will be found of great assistance. Containing, as it does, all the factors of the B complex, together with a high content of available iron, Bemax is widely used in Maternity Hospitals for its effect on lactation. One ounce provides—

Vitamin A ..	280 i.u.	P.P. factor ..	1.1 mg.
Vitamin B_1 ..	400 i.u.	Vitamin B_6	richest source
Vitamin B_2 ..	0.9 mg.	Vitamin E	Approx. 8 mg.
Iron	3 mg.	Phosphorus ..	330 mg.
Copper ..	0.45 mg.	Magnesium ..	99 mg.

NEW ASPECTS OF THE USE OF VITAMIN B

The present interest in the importance of diets rich in vitamins is mainly directed to their value in promoting a high level of general health and the capacity for increased output of work without undue fatigue. The use of high vitamin therapy in the relief of pain is a newer concept. Yet such forms of severe pain as that of certain types of neuritis, trigeminal neuritis and varicose ulceration can often be relieved and controlled by this means.

A preliminary course of injections of pure vitamin B_1 (Befortiss Ampoules, 2, 10 and 25 mg.) for high vitamin B_1 dosage should be followed by routine enrichment of the diet with Bemax. Apart from the improvement in general health, there is often a diminution of the symptoms.

Vitamin B_1 with other factors of the B Complex

Clinical experiments with vitamin B_6 (*J.A.M.A.* 115.3.209) show its effects in toxic peripheral neuritis, and on the haemopoietic system (*Nature*, 1940, 145, 388). Its effect on the skin is well known. Vitamin B_6 and other factors of the B complex are present with vitamin B_1 in Befortiss Tablets. Befortiss Tablets are available in two strengths—200 i.u. per gramme and 2 mg. (666 i.u. per gramme).

Descriptive literature and clinical samples of Pregnavite, Bemax, Fertilol, or Befortiss Tablets and Ampoules sent on request. Please state product(s) in which you are interested.

Vitamins Ltd. (Dept. BXA), 23, Upper Mall, London, W.6.

Products of Vitamins Ltd.

BEFORTISS :	For high vitamin B dosage.
BEMAX :	Stabilized wheat embryo.
COMPLEVITE :	A complete vitamin and mineral supplement.
FERTILOL :	A highly active, stable source of vitamin E.
PREGNAVITE :	A vitamin and mineral supplement for use during pregnancy.

diarrhoea, and the like. From May to October no bedclothes could be worn. Even the fine net to protect from sand flies and mosquitoes was at times oppressive. The temperature in midsummer ranged from 98° F. to 103° F. in the day-time, and usually about 85° F. at night. There could hardly be any chill at such temperatures. By July there is usually a breeze known to the Egyptian as the Nile wind but mostly the nights are only too still.—I am, etc.,

JAMES W. BARRETT, Lt.-Col., A.A.M.C.

Melbourne, March 25.

Treatment of Rectal Carcinoma

SIR,—I regret the unavoidable delay in answering Mr. W. B Gabriel's letter (March 29, p. 492).

My cases were judged inoperable on the usual ground of firm adhesion, the decision being made in the first instance by one or other of my surgical colleagues. The estimation of operability is, of course, a personal matter, and I have no doubt that in a special hospital the criterion may be different from that which obtains in a general hospital. While admitting that the more general performance of laparotomy may be desirable to settle the question, I cannot agree that, if this shows a case to be inoperable, colostomy should be carried out as a matter of course. The whole point of my article was, in fact, to show the opposite, and I hope that Mr. Gabriel and others will give my suggestion an extended trial. I agree, however, that if the anal canal is involved colostomy is desirable.

In none of the four cases which I described was biopsy performed. Recent examination of them showed that each had a firm adherent mass. In one of them the proctoscope revealed slight superficial haemorrhage, but in none was there any ulceration.—I am, etc.,

Cambridge, June 2. FF. ROBERTS.

Treatment of Diphtheria

SIR,—In my opinion, the use of sulphapyridine and other sulphonamides in the treatment of diphtheria should be discouraged until there is evidence that sulphonamides can deal effectively with organisms localized in the throat. Scarlet fever may be regarded as being similar to diphtheria in that the causal organisms growing in the throat produce most of the symptoms by toxins which are absorbed by the lymphatics. In a series of some 500 consecutive cases of scarlet fever I treated alternate patients with sulphanilamide. In the two groups thus obtained there was no appreciable difference regarding either the severity and length of the initial feverish illness or the incidence of complications. This is in agreement with the findings of other physicians. Sulphonamide therapy, though useful in other infections with haemolytic streptococci, thus appears to be useless in combating haemolytic streptococcal infections of the fauces, such as scarlet fever. In the treatment of diphtheria, therefore, the following considerations should be kept in mind: (1) The disease is produced by toxic absorption from a localized infection. (2) Sulphonamide drugs act on bacteria not on toxins. (3) Sulphonamides are effective only when the pathogenic organisms are in, or can be easily reached by, the blood or tissue fluids. Thus lung abscess and empyema following pneumonia, or abscess due to erysipelas, do not respond to sulphonamides though the initial infection is amenable to this treatment. (4) Bacteria growing in the throat may be regarded as being inaccessible to sulphonamides in the blood or tissue fluids.

My experience with vitamin B_1 in the treatment of diphtheria tends to support the evidence produced by Drs. G. E. Donovan and M. Bannister (March 8, p. 359). Of four severe cases recently all were given vitamin B_1 parenterally from the time of admission, and all developed severe nervous or circulatory complications about the third week. One patient died in the fifth week after progressive palatal and pharyngeal paralysis and acute circulatory failure; one recovered (only after three weeks) from severe palatal paresis with circulatory failure (gallop rhythm); one recovered after palatal paresis and threatened cardiac failure (bradycardia); one recovered from severe palatal paresis. My opinion is that vitamin B is a useful tonic in debilitated states, but it is not a specific for the nervous or circulatory complications of diphtheria, either as a curative or as a prophylactic measure.—I am, etc.,

Thornton, Fife, May 26. JAMES B. FLEMING.

After-treatment of Paraplegic Patients

SIR,—Lieut.-Colonel E. A. Gowlland's article (May 31, p. 814) on the after-care of paraplegic patients, carrying as it does the weight of extensive experience, is most opportune as it outlines clearly the essential points in the treatment of late cases. A reference to early treatment, however, is open to argument. One of his two conclusions was the necessity for the freeing of pressure on the spinal cord by laminectomy. In practice laminectomy is very seldom indicated and cannot compare in importance with the correction of bony deformity by manipulation. A depressed fracture of the laminae, the most obvious indication for the operation, is relatively uncommon, and not infrequently causes irreparable damage to the cord. Again, metallic bodies in the spinal canal are generally best left alone.—I am, etc.,

Stanmore, June 5. K. I. NISSEN, F.R.C.S.

Epidemic Dropsy and Toxic Oils

SIR,—May I draw your attention to a reference made by you in your issue of November 16, 1940 (p. 681), to the recent work on the causation of epidemic dropsy carried out at the All-India Institute of Hygiene and Public Health, Calcutta. The concluding sentence suggests that the disease is caused by the use of raw untreated oil in food and in the oil bath. This, read in conjunction with the sentences preceding it, would suggest that the use of the oil as culinary fat is free from danger. On the other hand, our studies[1] support the view that the practice of anointing the body with the toxic oil is probably harmless, whereas the heating of the oil as it occurs in the process of cooking meat, fish, or vegetables, which does involve fuming, causes the disease. However, as judged by chemical tests, the oil becomes detoxicated on exposure to sunlight (not necessarily ultra-violet light), especially in the presence of air.[2] Further work, shortly to be reported, shows that animal and human feeding tests confirm the above findings.—I am, etc.,

R. B. LAL, M.B., B.S., D.P.H., D.T.M.&H.,
Professor of Epidemiology and Vital Statistics, and Officer in Charge, Epidemic Dropsy Inquiry.

Calcutta, Feb. 26

Silk in the Darning of Hernias

SIR,—The correspondence on this subject in the *Journal* revives old memories on the part of a general practitioner who some forty-five years ago was a dresser to the late Frank T. Paul of revered memory. Over and over again did that great surgeon impress upon the students of the Liverpool Royal Infirmary never to bury silk, on account of its permanence, its readiness to become a nidus for germs, and its powers as a tissue irritant—all these illustrated out of the wealth of his experience. Myself having one day mentioned this matter to Thelwall Thomas then assistant surgeon at the Royal, he said that if one used fine silk and sterilized it well one had nothing to fear. It was only a short while afterwards that he showed me a persistent sinus following the use of silk in a femoral herniotomy, and told me that he had abandoned the use of buried silk.

In the long years that have passed since then I have met with abundant proof of the soundness of Paul's teaching, and would not willingly submit a patient of mine to the risks of buried silk.—I am, etc.,

Harston, Cambridge, June 7. W. J. YOUNG.

Physical Medicine and Orthopaedics

SIR,—The letters from orthopaedic surgeons (May 24, p. 791) call for vigorous protest. Physical medicine does not give poor results when properly applied in suitable cases (was not the life of King George V prolonged by ultra-violet rays and diathermy?); neither need inertia be caused; and the suggestion that physical medicine can only survive as a part of orthopaedic treatment is ludicrous.

What is physical medicine? An enormously wide part of therapeutics. It includes treatment by physical agents such as electricity (alternating, direct, high-frequency, and static), water (plain or medicated), massage, exercise, manipulation,

[1] Lal, R. B., *et al.*, *Indian J. med. Res.*, 1937, 25, 201; 1939, 27, 209.
[2] Idem, *ibid.*, 1940, 28, 173.

etc.; rays (radium, χ rays, ultra-violet, infra-red), climate, diet, and so on. What is orthopaedic surgery? Mr. Harry Platt answers by quoting Sir Robert Jones: "The treatment by manipulation, operation, re-education, and rehabilitation, of the injuries and diseases of the locomotor system." Thus it is evident that orthopaedics is a branch of physical medicine, as are radiology, electrotherapy, hydrotherapy, and the rest.

Orthopaedic surgeons cannot be expected to have adequate knowledge of all the various means employed in physical medicine. Other physical methods than orthopaedic are used successfully in such diseases as lupus, rickets, sinusitis, otitis, pneumonia, to mention only five which the strict orthopaedic surgeon would not treat. As regards the title "orthopaedic physician," this limits activity to the orthopaedic section alone. There can be no really comprehensive title for the practitioner in physical medicine, as the subject has become so all-embracing.—I am, etc.,

ARTHUR T. SPOOR,
Lecturer in Physiotherapeutics, Bristol University.

May 25.

SIR,—I read with great interest Mr. Harry Platt's letter (May 24, p. 791). There can be few who would disagree with the principle of unity of control in treatment throughout the course of an illness.

He specifies the rheumatic diseases as the responsibility of the physician and deplores the subletting of therapeutic procedure. With this I heartily agree. In this group of diseases the knowledge and practical experience of a general physician are essential in many cases to obtain a correct diagnosis and consequently sound treatment. But for the successful unity of control in treatment the physician must have a full knowledge of physical therapy, plaster technique, and manipulative procedure, only being dependent on a surgical colleague for operation details. In fact, he should be a general physician.

Prof. Davidson stated some four years ago that improvement in the treatment of rheumatic diseases would lie in the progress of medical orthopaedics, and so I would disagree with Mr. Platt in his remark that the "orthopaedic physician" of the future—a term which I hope will never come into use—should be drawn from the ranks of the fully trained surgeons. The conditions with which these men deal will be chiefly medical conditions, and they must be primarily fully trained physicians, and, secondly, have a knowledge of medical orthopaedics.—I am, etc.,

OSWALD SAVAGE.

London, W.1, May 27.

SIR,—I have read your annotation and the correspondence on this subject with much interest. There are a number of important and useful points in all of them, and I think that the majority of physiotherapists would strongly support any scheme for the expansion of the physical medicine services provided for the Armed Forces. There is a very real demand for adequate and appropriate service for the Forces both at home and abroad on account of the economic value of prevention of loss of function and of rapid restoration of function, which are the aims of physical medicine.

The consultant in physical medicine to the Army and his staff are doing most valuable work, but expansion of the present service is required, since a great burden is being put on to the civilian hospitals with E.M.S. facilities by Service patients who require treatment in their departments of physical medicine, and very often these patients come great distances to have their treatment in these departments. From the military and other Service hospitals over-seas one continually hears of the demand for adequate departments of physical medicine, and, therefore, it is hoped that an adequate expansion of the present service will come into being to cope with these requirements.

Sir Morton Smart, in his letter (May 24, p. 792), puts forward an extremely sound constructive scheme for a committee of physiotherapists, with power to act, to be set up to advise and to develop any such plan, and I think that this suggestion would meet with the strong support of all physiotherapists. The shortage of adequately qualified specialists in physical medicine affords some difficulty in providing them for both the civilian and the military services. For this purpose, therefore, it is well worth while considering the appointment of physiotherapists, as in the last war, in each large centre, who would be in the R.A.M.C. and who could look after departments in both the military and civilian hospitals in that area. It is also important to have an adequate supply of qualified masseuses for the Service departments and not merely orderlies with a brief training.

I also support the letter from the British Orthopaedic Association. I consider that the physical medicine specialist should be not a technician but a good clinician with higher academic qualifications and large general experience of all branches of medicine and surgery, who has also knowledge of the types and methods of physical treatment, applied psychology, and social welfare. There are also good "orthopaedic physicians" to-day who can compare in diagnostic efficiency with their surgical colleagues.

The function of the physical medicine specialist is to work in the closest collaboration with his brother practitioners and to help them in the realm of preventive medicine, diagnosis, and treatment, bearing before him the aims mentioned above —of prevention of loss of function and restoration of function. This collaboration can always be close and of mutual benefit. There is no need for difference of opinion from the orthopaedic surgeons, with whom, in Oxford at any rate, there is always the closest co-operation.

In the cases in which psychological and medical factors play a part the physical medicine specialist can offer invaluable help to the orthopaedic surgeon. The complete unit required for restoration of function under the specialist in physical medicine, and in which he would play an important part in controlling the personnel, would consist of three parts: (1) a department of physical education and treatment; (2) a department of occupational therapy; (3) a department of rehabilitation in which vocational suitability, guidance, and training should be established. Patients suffering from organic or psychological disorder, or both, could be treated in one or more of these departments, which would work together.

While the various types of physical treatment such as manipulation, massage, electricity, and hydrotherapy have a definite important adjuvant part to play, the main principle in departments of physical medicine should be "active movements of mind and body of the right type at the right moment."—I am, etc.,

BASIL KIERNANDER, M.B., B.S., M.R.C.P., D.M.R.E.
Radcliffe Infirmary, Oxford, May 30.

"Bureaucratic Surgery"

SIR,—Mr. Norman Lake's excellent letter on bureaucratic surgery and the subsequent correspondence in the *Journal* have raised issues that have been exercising the minds of many for a considerable time. The arguments offered in defence of the special units and the claim for the monopoly by a few in wide fields of surgery, even to the inclusion of burns, scalp wounds, etc., have not as yet been wholly convincing. For instance, one of the main contentions appears to be that some cases reaching the special centres have been badly treated, and therefore all such cases, however trivial, should be sent in the first place to these special centres. Is it not possible that many cases treated successfully by the unknown surgeons are never seen at the special units to offset the failures that arrive there, and that good work can be done in many of the lowly shrines as well as in the temples of the high priests? Does the title "specialist," whether having been justly earned or merely acquired, assure a 100% success in contrast to the poor results of others? Are there no failures in the special units themselves, even at the hands of the high and mighty? I wonder if their work would be so infallible if they had to work under the conditions that many have to face in the hospitals that provide the necessary medical treatment. Perhaps even in their hands the razor would sometimes falter before the scalp was bared to perfection.

However, the recent correspondence has opened up much wider issues than suggested by the title under which it has appeared. These are really concerned with the whole system of the country's medical services in wartime, and I hope it will be understood that the following remarks are directed at the principles of that system and not at any particular individuals. Admittedly, much advancement in knowledge might be derived by the concentration of material for the exclusive use of experts in clinical research, but which of the three groups involved will benefit most from this advancement the personnel of the clinic, the body of the medical profession, or the experimental animal, the general public? Is there not a danger that centres created ostensibly for the greater perfection of treatment and the ultimate benefit of

the public might soon merely provide an opportunity, not necessarily deliberately calculated, for the advancement of the practitioners who derive from them the exclusive rights of experience and advertisement? At least one famous American clinic appears to have been tainted with suspicion in this way.

There are many who think that reorganization of the Emergency Medical Service is long overdue. The trend of medical organization in modern warfare has been to distribute the medical services so that the patient might be treated skilfully as soon as possible after the infliction of the injury, and not be merely temporarily patched up and relayed for proper treatment to base units which it might take a considerable time to reach. However, in many of the E.M.S. hospitals of this country, existing solely for the early treatment of the injured, students, newly qualified housemen, and even fully fledged surgeons walk the deserted wards and corridors without any work from which to learn that necessary skill.

Could not the work be more evenly distributed among the hospitals of the country, with regular inspection by qualified people to see that it was done adequately? Then the whole medical personnel might have the opportunity to obtain the experience that is necessary for the successful early treatment of the sick and injured, instead of this being reserved for the few who are fortunate enough to be appointed, either by influence or good luck, to the few special centres. By this means a far greater proportion of students could be adequately trained for the fighting Services than at present, and all would be given an equal chance. Also, a more accurate assessment of the available medical and surgical talent in the country could be formed, and a better use made of it, to the greater benefit of the public, which means the greater welfare of the State, which should be our only aim in total war.

The travelling consultant would need to be truly skilled and competent in his specialty, and be appointed for that and no other reason. He must also be unbiased, without any special interests in the products of one medical school or another, or in any particular group of people. Perhaps it might be suggested that there would be a shortage of suitable specialists for this work, but if search were made occasionally beyond the confines of the teaching hospitals it might not prove so difficult.

The true goal of medical progress should surely be the provision for the public of as widespread, in addition to as competent, a service as possible, rather than skilled treatment ("skilled" being sometimes, alas! merely a *courtesy* description) at the hands of a privileged few, with the consequent higher cost to the patient that goes with monopoly. There are many surgeons in the E.M.S. who have been waiting since war was declared to try to save the lives of the sick and injured and play their part in the war effort. Such, however, has been the growth of special departments, and the creation of centres in which those with influence or authority are primarily interested, that the bulk of the cases have been taken by them, and the waiting surgeons are still waiting with no lives to save.

Can it be that those who have found themselves in commanding positions during the war are using their temporary powers to ensure for the groups in which they are interested a first claim to appointments afterwards in case State Medicine becomes a reality, and are excluding others from competition by denying them access to experience now, and thus reducing indirectly the value of the total war *effort* of the professional?—I am, etc.,

London, E.2, June 2. G. R. BUTTERFIELD.

Medical Planning Commission

SIR,—Close examination of the report of the first meeting of the Medical Planning Commission (May 17, p. 759) reveals no obvious evidence of appreciation by the Commission of the necessity to co-ordinate short-view medical planning with the various aspects of planning in other spheres such as agriculture and urban reconstruction. For instance, it seems to me most unlikely that the Army—now an efficient technical machine—will be disintegrated, on cessation of hostilities, into labour exchange queues. It may be retained, complete with medical personnel, and diverted more or less *en masse* to immediate agricultural, etc., requirements. Thus, medical planning out of step with such plans as may be in the minds of the Army authorities may have to be modified out of all recognition when national post-war plans are constructed.

I would therefore like to suggest to the Medical Planning Commission that a special political subcommittee be chosen for the express purpose of maintaining political contacts with the Ministries. This will enable the Commission to implement its findings, when the time comes, instead of scrapping them, as so many commissions have had to do.—I am, etc.,

Kearsley, Lancs., May 31. D. OCKHAM.

SIR,—In the report of proceedings of the Medical Planning Commission meeting (*Journal*, May 17, p. 759) it is stated that they hope to have a preliminary report to submit at the end of this or early next year. At this rate when are we to expect hearing of any definite proposed plan of action? Already the Minister of Health is proposing to include another half-million private patients in the N.H.I. scheme. Does this not call for more immediate action? It is to be regretted that Dr. Stark Murray's proposition was not adopted to consider domiciliary services and preventive medicine as a whole rather than to have committees investigating the separate branches. One of our present troubles is the lack of co-ordination between the various services.

Would it not have been a wise step to find out the attitude of the profession as a whole towards the future of our medical services? This could easily be done by some body such as the B.M.A. sending out a very brief questionary to all registered practitioners on the following lines:

(1) Are you satisfied with the present medical system?.....
(2) If not, is it because
  (a) it fails to give the best treatment to the people as a whole? .....
  (b) it fails to give satisfactory conditions of service to the practitioners? .....
(3) Are you in favour of a State Medical Service? .....
(4) Are you in favour of extension of the N.H.I. as proposed by the Minister of Health? .....

A questionary on these lines would certainly give the M.P.C. some idea of the feelings of the profession.

One of the great arguments against a State Medical Service is that of free choice of doctor. It is used by the opponents because it might appeal to the masses, but it is a greatly overrated argument. *I quite agree with Dr. S. F. Marwood* (*Supplement*, May 17, p. 96) when he describes it as a bogy, and surely anyone reading that article must be convinced that the argument of free choice of doctor is a myth.—I am, etc.,

Wetherby, May 27. S. TERRY PYBUS, M.B.

Medical Man-power

SIR,—I have read with shocked amazement Dr. C. A. H. Franklyn's letter (May 3, p. 600) and with your permission I will roughly analyse and supplement it.

(1) 35,000 doctors are engaged in active practice in England and Wales.

(2) Of these, according to Dr. Franklyn's estimate, the Forces (3,000,000 healthy men) have been allotted a grand total of 10,000—(30%)

(3) This represents three doctors to every thousand of the nation's fittest men, whereas in times of peace one doctor to a thousand laymen is the standard ratio.

(4) Bitter experience taught us how useless was a doctor (at £2,000 and five years' training!) in front-line warfare twenty-five years back.

(5) None the less, to-day, with every one of us permanently in the "front line," nearly one-third of our trained surgeons and physicians are side-tracked into office work—or else appointed to the care of minor ailments. Serious cases are transferred to general hospitals for treatment by the remaining 25,000 qualified men in mufti. Here is short-sighted economy indeed; for while the "soldier doctor" renders first aid to 300 men at £450 p.a., his civilian colleague is responsible not for a peacetime average of 1,000 laymen but for nearly 1,700 "front-liners"—and in our crowded hospitals the senior "honoraries" still receive a nominal £50 a year.

Having regard to these facts, I shrink from setting out a responsibility/work/pay ratio in black and white. But one irrefutable example may be better than abstract mathematics.

A year ago the British Army in Dunkirk was conjured home, and the great bulk of the casualties came streaming into

a hospital whose peacetime home is London. Some men were so exhausted that an 80% oxygen, 20% gas mixture alone induced deep anaesthesia! Each theatre in the hospital worked at high pressure for a fortnight—twenty hours a day and three tables to each theatre. The two (honorary) anaesthetists who wrestled with this task wore—mufti. They do so still; and foot their tailors' bills. These facts can easily be verified.

May I suggest that further comment is superfluous, but that prompt and effective reorganization of our "medical man-power" is, in the interests of common decency, clearly imperative?—I am, etc.,

H. BUCKLAND.

Bournemouth, May 28.

SIR,—I should like to congratulate Dr. James Fettes on his letter (May 31, p. 834) concerning medical man-power. There is in fact a reserve of British medical man-power in London, and almost certainly in the other target areas, waiting to be used.

Dr. Sanguinetti hints at financial difficulties without going into details. There seems to be some shyness in mentioning that many of us who are hanging on by the most precarious of holds and at the risk of life and limb are doing so for the benefit of those who in better times were willing to lend us the money with which to buy house and practice. How can I go off and leave an investment worth nearly £5,000, hardly any of which was my own money? The company to which I remain chiefly indebted have treated me with sympathy and understanding, although I must admit that I was irked to be told at the outbreak of hostilities that my debt was largely a matter of "honour." No question of honour had been raised when the apparently ample security for the loan was originally under discussion.

Your advertisement columns tell me that I can earn about £650 if I betake myself as assistant to a reception area. Out of that I must continue to find mortgagé interest, ground rent, rates or storage, and other incidental outgoings in which one must include about £100 per annum in insurance policies which are bound up with the mortgage. With the remainder I must try to provide for a wife and three children of school age.

I wrote pointing out some of the difficulties of this sort of position to an M.P. who is most anxious that the shortage of doctors should be made up by giving employment to those aliens of enemy origin who are now in refuge in this country. I did not receive the courtesy of an acknowledgment.

One's feelings are akin to those said to have been experienced by a man who was holding a ferocious wolf by the ears.—I am, etc.,

DONALD M. O'CONNOR.

London, S.E., June 1.

Medical Certification

SIR,—In these times when we are troubled so much with requests for this and that kind of medical certificate, it would greatly help the doctor's position if some printed form were supplied to be displayed in the waiting room. The days of the "heavy father" kind of medical man who could bully the neighbourhood are gone for ever, and we are now regarded as more or less bound to "oblige" our patients in their every whim and fancy. I suggest that the B.M.A. should supply us with some such notice as this:

BRITISH MEDICAL ASSOCIATION

MEDICAL CERTIFICATION

The attention of the public is drawn to the following rules regarding certification, breach of which may render a doctor liable to serious penalties.

1. A doctor may not issue a certificate unless he has seen the recipient on the date stated on the certificate.

2. A doctor may not put anything on a certificate which is not the result of his own observation.

3. No certificate may be issued to excuse absenteeism from work if the applicant has not been receiving medical treatment for the illness or other condition causing the absence from work.

4. No certificate can be issued to render it easier for a person to change his employment unless the applicant has received treatment for the alleged condition for at least six months prior to the application.

—and other such rules as may fit the moment.—I am, etc.,

JOHN UNSWORTH.

Leach Lane, St. Helens, May 31.

Obituary

SIR D'ARCY POWER

Prof. G. GREY TURNER writes: If space permits I should like to add a few personal memories of the "G.O.M. of Bart's" to your admirable obituary notice.

Not so very long ago I was asking Sir D'Arcy Power about his association with one of the great figures in our profession. While agreeing in admiration for the surgical prowess and scientific ardour of the person in question, Sir D'Arcy went out of his way to state, and with some heat, that he had been a very bad examiner. To my surprised inquiry about the reason, I was told that he had always tried to find out what the candidate did not know. Like a flash, recollection carried me back forty-six years to the time when, as a callow youth, I had first confronted Sir D'Arcy as an examiner in physiology, and in retrospect I realized that at the outset of my career he had given me much-needed encouragement by endeavouring to discover what little I did know about that subject. Since that early meeting Sir D'Arcy proved guide, philosopher, and friend, and I cherish large numbers of communications that have passed between us—letters, notes, and short messages on post-cards, but always delightful. He loved to incorporate some little pleasantry, some quip or gibe, but they were always apt and never hurt. If he could do a good turn he was pleased from him arrived as recently as February, when, in spite of advancing years and increasing disabilities, he was going out of his way in an endeavour to help me. At the outset of my surgical career he made me swell with pride by quoting a case I had recorded in a trivial paper in our local medical journal. Thereafter he introduced me to his paper on "Introsusception" and aroused my interest in the great collection at the College of Surgeons by telling me about the microscopical examination of an age-old Hunterian specimen. Then came a kindly note of appreciation about an account I had published on Perceval Pott, mildly directing my attention to an error into which I had fallen. Since there are so many of us, it is refreshing to find that there are some few learned ones who suffer us with helpful compassion and perhaps even gladly.

November 14 last was a memorable day, for after sharing a wartime lunch arranged in his honour by the Council of the College, Sir D'Arcy attended our monthly meeting and handed to the President the material for the first supplement to *Plarr's Lives of the Fellows*. This comprised two volumes of type-script containing notices of the lives of the 400 Fellows who had died since the original publication ten years ago. In the first instance every one of these notices had been written by Sir D'Arcy's own hand, and their compilation had involved great labour in the way of research and inquiries. But, lame and breathless, he was not to be robbed of his little joke as he reminded the Council that in the next supplement, on which he was already engaged, his own necrology must appear. Devotion to hospital duty was always a byword strictly observed at Bart's, and this tradition must explain the little story, almost certainly true, about the occasion in 1882 when young D'Arcy Power was rather late for eight o'clock surgery one morning, apologizing and explaining that he had been a little delayed as he had been getting married on the way down to the hospital. The same urge to follow the traditions of the hospital impelled him to go down at night and often on a bicycle to do his own emergency operations, almost to the end of his service at the mature age of 65, because it was a duty specified in the "Charter."

No one did more to stimulate the study of the history of surgery, for he made the subject so real and interesting, and so alive. The reader of his papers was brought face to face with the actual persons, so that the mediaeval surgeons came to life almost as if in a dream. The long series of Eponyms which he contributed to the *British Journal of Surgery* gave great pleasure and there was wide regret when they came to an end. Notwithstanding his deep learning, he was a practical antiquarian, who during a saunter in the City could make the stones of the London he knew so well reveal their fascinating story. I was glad to see that you had mentioned his purely professional contributions to the literature, for many

surgeons will recall lessons pleasantly conveyed by his pen. I am always grateful for one communication on ruptured peptic ulcer (I cannot vouch for the title, but that was the subject), in which he made a plea for the minimum of interference and the greatest simplicity in operating—a valuable doctrine not yet sufficiently followed. In fact, it was Sir D'Arcy's advocacy of the sufficiency of these simple measures which suggested to my mind the application of the aphorism of Laotze to surgery. "The State is best governed as you cook little fish without much busyness." Though most of his papers were direct and simple, there were some with a deeper meaning, and I have always remembered his striking clinical lecture delivered at Bart's in 1915 on some aspects of venereal disease under the title "Against His Own Body." This lecture might serve a very useful purpose if it were reprinted to-day. But Sir D'Arcy had very many qualities which made him valuable to the medical community, as witnessed, for instance, by his long tenure of office as treasurer of the *British Journal of Surgery*. He was a great host, a notable diner, and an authority on wines, but, above all else in this sphere, a delightful and entertaining companion. The unusual interest evinced in the passing of one at the advanced age of 85 is in itself noteworthy testimony to the worth of his years. It might be said of Sir D'Arcy as Sir James Paget said of Stanley one of the Bart's surgeons of his own early days, ". . . . he was completely honest, true and truth-loving, keenly conscious of his duty and resolute in doing it." In addition, few men can have had better developed the gift for sustained, helpful, cheerful friendship.

H. ELWIN HARRIS, M.A., M.B., F.R.C.S.

Herbert Elwin Harris, formerly of Bristol, who died on May 20, was born in 1860 at Binham in Norfolk and was baptized in the beautiful old Norman abbey church there. His father, like many of his forbears, was a gentleman farmer who lived in a house facing the green; his mother, a Miss Wrench, came of another old Norfolk family.

He was educated at his uncle's school in Truro, whence he proceeded to Christ's College, Cambridge, and graduated in the Mathematical Tripos in 1882. He was destined for holy orders, but he persuaded his college tutor to allow him to read Medicine as well as Mathematics and he passed his first M.B. whilst preparing for the Tripos. After this his father consented to his continuing the medical curriculum and he went from Cambridge to St Bartholomew's, where he was a dresser under Sir William Savory. He took the qualifications of M.R.C.S. in 1885, L.R.C.P. in 1886, and M.B. Cambridge in 1886. After leaving Bart's he was a house-surgeon at Plymouth and then worked for several years in various London poor-law infirmaries, ending with a long period at St Saviour's, Dulwich. In 1890 he took the F.R.C.S. and settled in general practice in Bristol, where he was soon appointed anaesthetist at the Royal Hospital for Women and Children. A few years later he was elected to a vacancy as surgeon and became also surgeon in charge of the ear, nose, and throat department.

During the 1914-18 war Dr. Harris was captain R.A.M.C.(T.) on the *à la suite* staff of the Second Southern (Territorial) General Hospital and worked in the Beaufort War Hospital at Fishponds, Bristol. He was one of the last in Bristol to combine general practice with operative surgery, and he achieved success in both branches of practice. During his earlier years in practice Dr. Harris was almost hobbyless. His recreation was cycling, and in the fashion of the time he would ride vast distances in a day. Presently, however, he became an enthusiastic gardener and photographer. He was one of the first doctors in Bristol to drive a motor-car, and he was distinguished by favouring an open two-seater with a blue body and yellow wheels, which always looked new. However often he changed his old car for a new one he retained the original registration number.

Dr. Harris was President of the Bristol Medico-Chirurgical Society in 1933-4, and for forty-two years was a member of the British Medical Association. In 1934 he retired from practice to live for the rest of his life at Halse, near Taunton. There he died suddenly of coronary thrombosis, in the garden he so dearly loved, within a few weeks of his eighty-first birthday. Dr. Harris was widely known and well loved, especially by his patients, in whose interests he worked himself sparingly. He yielded to no one in his admiration for his old teacher, Sir James Paget, a Norfolk man like himself, from whom perhaps he had caught something of the kindly courtesy which was one of his outstanding characteristics. He was succeeded in his practice by his son, who had helped him for some ten years before his death.

SIDNEY DAVIES, M.A., M.D., D.P.H.

Dr Sidney Davies, for twenty-eight years medical officer of health for Woolwich, died at his home in Worthing on May 18.

Born in 1855 at Darwen, he was educated at Manchester Grammar School, Oxford University, St. Bartholomew's, and Paris. He graduated B.A. in 1877, gaining first-class honours in mathematics. He won the junior entrance scholarship at Bart's in 1878. He qualified M.R.C.S. in 1881 and M.B. in 1883 and took his M.D. in 1889. After holding a resident appointment at the Prince of Wales's Hospital, he went to Egypt, where he became principal medical officer to the Egyptian Police. In 1888 Dr. Davies settled in general practice and in 1891 he was appointed M.O.H. for Plumstead. In 1901, when Woolwich became a borough, he became its first M.O.H. and retired in 1919. During his period of service in Woolwich he introduced the first garden shelters for the treatment of tuberculosis, and was the first M.O.H. to employ women as sanitary inspectors. He was also the first M.O.H. to have notices put up in the public conveniences about venereal disease. He began the first maternity and child welfare clinic in Woolwich, which now has one of the finest organizations in this department in the country.

S. R. E. D.

An old friend writes:

One of our veterans of the Public Health Services has now "joined the majority," and it falls to me, also an octogenarian, to write a few words of appreciation. I fear that many others, like myself, failed to realize how well informed Sidney Davies was and the admirable work in public health that he accomplished. He was not an advertiser of what he had done, and it may be said of him that he suffered from the rare complaint of modesty, perhaps to an excessive extent. But nevertheless his work was done and well done, without any fuss being made; and when the books come to be made up, his work in the ordinary sanitation of Woolwich, and in the special new developments of tuberculosis, of maternity and child welfare work, of the treatment and prevention of venereal disease—all newly developed in Woolwich under his leadership—will make it clear that he left Woolwich a different and immensely better area than he had found it. In postscript to his biography, one specially original piece of work, carried out jointly with Dr. J. C. Thomas of the L.C.C., is outstanding. Thus was on the experience of measles in the school population of Woolwich—a valuable early study of the epidemiology of that disease. Most of the original and specially important work of medical officers of health is interred in their annual reports, and it may be regarded as a major defect of our publicity work in public health that a special and often difficult process of disinterment is required for giving it the continued life that it deserves. That was especially so for Sidney Davies. But the good influence of such reports continues and increases with time, until what was individual becomes in time the possession of all.

W. F. BROOK, F.R.C.S.

Consulting Surgeon, Swansea General Hospital

Mr. William Frederick Brook, the well-known Glamorganshire surgeon, died on May 26 at Pennard, near Swansea, after a painful illness.

He was born at Wye, Kent, in 1861, and from King Edward VI School, Berkhamsted, entered St. Thomas's Hospital, taking the L.S.A. in 1886, the M.R.C.S. in 1887, and the F.R.C.S. in 1889. For two years he held house appointments at St. Thomas's, at the Hospital for Sick Children, Great Ormond Street, and the West London Hospital. After settling in practice in South Wales he was elected surgeon to the Glamorgan County Infirmary in 1912, and not long afterwards surgeon to the Swansea General Hospital and to the Port Talbot General Hospital. During the last war he served with the rank of major R.A.M.C. (T.) on the surgical staff of the 3rd Western General Hospital, Cardiff.

Mr. Brook joined the British Medical Association in 1892; he was honorary local secretary for the Annual Meeting in

Swansea in 1903, and served on the Central Council in London for two periods. At the Annual Meeting at Oxford in 1904 he held office as vice-president of the Section of Surgery. He was a Fellow of the Association of Surgeons, of the Royal Society of Medicine, and of the Medical Society of London. His main appointment outside medical life was that of J.P. for Glamorgan. Between 1896 and 1908 he contributed six papers on surgical and radiological subjects to the *British Medical Journal*.

HARRY EDWARD MANSELL, B.M., F.R.C.P.

A career of high promise has been cut short by the death on June 1, at Lambeth Hospital, of Dr. Harry Edward Mansell, consulting cardiologist to the London County Council Hospital Service. He was the son of the late Dr. H. R. Mansell of Hastings. He had a brilliant student record at Oxford and St. George's Hospital before he took the M.R.C.S., L.R.C.P. in 1927, the B.M.Oxford in 1929, and the M.R.C.P. in 1930.

After filling rather more than the usual number of resident appointments, Mansell seemed fairly started on the road to an assistant physicianship at his own hospital and a West End consulting practice, when he was impressed with the opportunities afforded by the reorganization of the municipal hospital services of London proceeding, due to the Local Government Act of 1929, under the aegis of Dame Barrie Lambert and Sir Frederick Menzies. He accordingly sent in an application for a vacant medical superintendency: although he did not secure it, the committee before whom he appeared at County Hall were so impressed with his value as a recruit to their staff that they spontaneously offered him the appointment of deputy superintendent at the largest and in some ways the best equipped of their hospitals, at Lambeth. This he accepted, and after rendering good service there, during which he was laid low with diphtheria, Sir Frederick Menzies recommended him for appointment as cardiologist to the entire L.C.C. hospital organization; this was a post entirely after his own heart, for he disliked the divorce from clinical medicine at the bedside which so many of the higher posts in the L.C.C. on the administrative side necessarily entail to a greater or less extent. Mansell was a man of modest and attractive personality, who wore his learning lightly. He became a Fellow of the Royal College of Physicians in 1937; but his health was never robust, and his death at the early age of 40 is a serious loss to London. He leaves a widow and two young children.

R. H. P. ORDE, O.B.E.

Mr. R. H. P. Orde, who was well known to the medical profession as, until recently, honorary secretary of the British Hospitals Association and director of the Central Bureau of Hospital Information, died on May 24 in his seventy-fourth year.

His association with hospital administration began in 1898, and his first post was that of assistant secretary of the London Hospital. From there he went to Newcastle-upon-Tyne to become house governor at the Royal Victoria Infirmary. In 1922 he returned to London to take up an appointment in the medical department of the Joint Council of the Red Cross and St. John, which department was later reorganized under his direction as the Central Bureau. Under these auspices he was responsible as editor for that extraordinarily useful and encyclopaedic compilation, *The Hospitals Year Book*. Long before his honorary secretaryship of the British Hospitals Association began in 1929 his name was well known in the hospital world, and from that time forward he served on many Government and other commissions, including two recent interdepartmental committees, one on the nursing services and the other on the cost of hospitals. In all these matters his counsel and experience were of the greatest value. No man was better acquainted with British hospitals in all their great variety of administration or did more to bring hundreds of independent units into something like a common policy. He was the very man to serve as honorary secretary of the Voluntary Hospitals Commission, better known as the Sankey Commission, and one can only regret that a few more years were not given him in order to assist the present movement towards hospital regionalization which gained its first impetus from that Commission. Mr. Orde was a quiet man who knew his job, and in hospital circles he will be greatly missed.

The death took place on April 28 of Dr. ALEXANDER GLENCORSE HAYS of Woodford Halse, near Rugby. Dr. Hays took the Scottish triple qualification in 1896, and, after holding appointments for a short time at Glasgow and at Sheffield, settled down in practice in Northamptonshire, at first at Eydon and later at Woodford and Hinton. He was also surgeon to the London and North-Eastern Railway and medical referee to various assurance companies. During the last war he was medical officer to the Lady Fermor Hesketh Auxiliary Hospital at Eydon Hall, where hundreds of soldier patients passed through his hands. At one time he was a member of the Daventry board of guardians and of the rural district council. Outside his practice his interests lay in music, horticulture and Freemasonry (he had been a member of his lodge for nearly sixty years). He was the founder and conductor of a local choral society and an orchestral society, an energetic promoter of the Boy Scout movement, and an organizer of first-aid and ambulance teaching and work, especially in connexion with the L.N.E. and L.M.S. Railways. During the last two or three years he was compelled by the after-effects of a road accident to relinquish a large part of his practice, and it gave him much happiness to know that his colleague Dr. A. E. Clayton was in charge.

The death in London, in April, of Dr. WILLIAM GARFIELD FORDE, through enemy action, will be regretted by many friends and patients in Australia, India, and England. "Bill" Forde (writes a correspondent) came from a well-known family in Cloyne, Co. Cork, and after medical studies and qualification in Edinburgh and at Trinity College, Dublin, he settled down to practice in Australia after a short period of employment in the Argentine. On the outbreak of war in 1914 he at once joined the Australian Expeditionary Forces, was present at the attack upon and occupation of New Guinea, and later proceeded to Egypt with the "Anzac" troops. After the war, and after holding a temporary appointment in Assam, he practised in Bombay for many years, and was known to a wide circle of patients (European and Indian) as a sound and hardworking practitioner. Possessed of a keen sense of humour, a distaste for humbug, a refusal to suffer fools gladly, and an Irish temper—"quick up and quick down"—he gave bold expression to his opinions on professional, political, social, and religious subjects without respect to the rank, wealth, or influence of his company. A keen student of medicine, a loyal member of the British Medical Association, he did not go out of his way to make friends or to seek popularity, but he acquired both in good measure. May he rest in peace.

Dr. CECIL FRANK MOORE died at Hatton on May 18. He was born at King's Newnham, near Rugby, the son of Judge Moore, and was educated at Sherborne School and at St. Bartholomew's Hospital. He had a regular place in the hospital first XI as a fast bowler, and played also in the second XV. He also played cricket during vacations for Warwickshire Club and Ground. In 1928 he qualified, taking honours in the London M.B., B.S. In this same year he won the Brackenbury scholarship and the Willet medal. Though strongly attracted to surgery, and obviously a young man of great promise (he had passed also the Primary F.R.C.S.), he took no higher qualifications but settled down almost at once in general practice at Slough. Here he was highly successful and worked exceedingly hard, probably too hard: he became public vaccinator and district medical officer, was divisional surgeon to the G.W.R. St. John Ambulance Brigade, and was medical examiner to various insurance companies. He was also a member of the Bucks National Health Insurance Committee. Some little time ago his health broke down, and though there were periods of temporary improvement—as recently as February and March of this year he was able to do a little light professional work—his friends realized that these were merely flashes in the pan and that no real recovery could be expected. He leaves a widow and one daughter.

The following well-known medical men have recently died abroad: Dr. PHILIP BEINART, a radiologist of Port Elizabeth, aged 36; Dr. PAUL GARNEAU, major in the Canadian Army and professor at Laval University, aged 45; Dr. GEDEON DESROSIERS of Quebec, probably the oldest practitioner in the province, aged 93; Dr. HENRY E. MENAGE, a prominent dermatologist of New Orleans, aged 66; and H. M. HOU-JENSEN, professor of anatomy at Copenhagen.

The Services

NAVAL AWARD

The D.S.O. has been awarded to Surgeon Lieut. Allan Gordon Campbell, R.N.V.R., for gallantry and distinguished services in the withdrawal from the beaches of Greece under fire and in the face of many and great difficulties of many thousands of troops of the Allied Armies.

R.N.V.R. OFFICERS' DECORATION

The King has approved the award of the Royal Naval Volunteer Reserve Officers' Decoration to Surgeon Commander C. C. Elliott, D.S.C., R.N.V.R.

HONORARY PHYSICIAN TO THE KING

Colonel C. A. Wood, M.C., I.M.S., has been appointed an Honorary Physician to the King in place of Major-General H. C. Buckley, I.M.S., who has retired

ROYAL AIR FORCE DIETARY

The Air Ministry has appointed a biochemist, Dr Thomas F. Macrae, and a specialist medical officer, Squadron Leader W. P. Stamm, to watch over the food supplied to the Royal Air Force, so as to ensure that the greatest nutritional value is obtained. The biochemist will analyse the foods, and carry out experiments to discover the existence and extent of any deficiency in vitamins, minerals, salts, proteins, carbohydrates, or fats. The specialist medical officer will watch for the earliest signs of food deficiency in the health of the men. Both will study the preparation and cooking of food at the various units, the planning of a balanced ration from the available supplies and the prevention of waste. Catering and messing officers were appointed some time ago throughout the R.A.F. to improve the dietary. With the addition of two experts on nutrition it is hoped to prevent any sickness from lack of essential foods, such as occurred at the end of the last war.

CASUALTIES IN THE MEDICAL SERVICES

Royal Navy

Surgeon Lieut. CHRISTOPHER HENRY CONGREVE DENT, R.N.V.R., who is reported as "Missing, Believed Killed" in H.M.S. *Hood*, was 27 years of age and was the younger son of Mr. Howard H. C. Dent, F.R.C.S., and Mrs. Dent of Pattingham, near Wolverhampton. From Marlborough he went up to Christ's College, Cambridge, where he won a scholarship and prize and gained first-class honours in Part I of the Natural Sciences Tripos in 1934 and was placed in the second class of Part II in 1935. He passed the third year at Cambridge acted as supervisor in anatomy for his college. At St Mary's Hospital he won the Harmsworth Scholarship, and distinguished himself in clinical studies. After qualifying, M.R.C.S., L.R.C.P. in 1938 he took the degrees of M.A., M.B., B.Chir. at Cambridge. He had held the posts of house-physician at Addenbrooke's Hospital, Cambridge, and house-surgeon at St. Mary's, and junior demonstrator in anatomy at Cambridge. He joined the R.N.V.R. in 1938 and was posted to H.M.S. *Hood* at the beginning of the war. Surgeon Lieut. Christopher Dent had been a member of the British Medical Association since qualification. A personal tribute to his character and his brilliant attainments appeared in the *Times* of June 7.

Wounded or Injured

Temporary Surgeon Lieut. Leonard Desmond de Launay, R.N.V.R.

Probationary Temporary Surgeon Lieut. George Heaton Daglish, R.N.V.R.

Royal Army Medical Corps

Major DAVID WARDROP lost his life last month by enemy air action. He was the son of Dr. David Wardrop, of Rugby, and was educated at the University of Birmingham and St Mary's Hospital, qualifying M.R.C.S., L.R.C.P. in 1928. He also obtained the F.R.C.S.Ed. in 1931. After qualification he lived at Rugby and had held the posts of surgical registrar, house-physician, and house-surgeon at the Birmingham General Hospital. In 1933 he moved to Wellingborough, where he stayed until 1936, finally settling in Seaford. In 1939 he contributed an article on the treatment of uterine haemorrhage by radium to the *Queen's Medical Magazine*. He leaves a widow and three children. He had been a member of the British Medical Association since 1933.

Major JAMES EDWARD COLLETON ROUSE lost his life on active service in the Middle East last month. He received his medical education at St. George's Hospital, where he won the Brackenbury Prize in Surgery, and qualified M.R.C.S., L.R.C.P. in 1925. Two years later he took the M.B., B.S. of the University of London and in 1936 obtained the D.A. of the Royal Colleges. He had held the posts of house-surgeon, house-physician, and resident anaesthetist at St. George's before settling in practice at Worthing, where he was honorary anaesthetist to the local hospital as well as to Hove General Hospital. He was also honorary medical officer to the Royal Surrey County Hospital Convalescent Home at Worthing and an honorary anaesthetist to the Royal Sussex County Hospital, Brighton. He was a Fellow of the Royal Society of Medicine and a member of the Brighton and Sussex Medico-Chirurgical Society. He leaves a widow.

Missing

Lieut. Oliver Ive.

Medico-Legal

LEGAL RESPONSIBILITY OF THE SURGEON

In an address to the Medico-Legal Society on May 29 Mr. ZACHARY COPE pointed out how relatively modern was the surgical operation on any extensive scale. Sixty years ago a surgical operation was a rarity; about 300 were done in the whole year at St. Mary's; now it was almost the exception to find someone who had not undergone an operation. The ability of the surgeon to cure disease had become accepted by the public to such an extent that often no persuasion was needed to get people to consent to a necessary operation, but the added responsibility of the surgeon which was thereby entailed came under notice only when a legal claim arose, and then it came as a shock to find that legal opinion varied and that no specific rules existed for the guidance of judge and jury. The law did not pay any special attention to the surgeon *qua* surgeon. It was open to any qualified practitioner, however meagre his qualifications, to attend at any operation, however severe and complicated, and sometimes the mere tyro would undertake something over which the most experienced surgeon was hesitant.

Consent to Operation

To the conscious patient of mature age it was the duty of the surgeon to explain the nature of the operation and to obtain consent. His own practice was also to mention possible alternative lines of treatment and outline the probable course of the disease if operation was refused. If there was refusal and the matter was urgent, he asked the patient to put his refusal in writing. He never overpersuaded the patient to consent, nor did he suggest that the most trivial operation was without some risk. When only a limited consent had been given there was no justification for going beyond it save in cases where life was at stake. On the other hand, it was often more difficult for the surgeon to refuse operation when this was besought by the patient or his relatives. Surgeons did not like to be rushed into operation by non-professional entreaty, yet lay opinion might occasionally be right. In any case in which the patient or relative doubted the surgeon's diagnosis, common sense and prudence should lead the surgeon to seek consultation with a professional colleague of acknowledged rank. Refusal to call in a consultant might lead judge and jury to award damages against him.

Responsibility in the Theatre

The responsibility of the surgeon in the operating theatre had been the subject of frequent legal debate. It used to be the rule that the surgeon was responsible for the acts of all those who assisted him, and faults of anaesthetists and nurses were visited on his head. Successive decisions had cleared the position to some extent, but there still remained some uncertainty in this matter. If the nurse gave the

anaesthetic a special responsibility rested on the surgeon. There were so many skilled anaesthetists in the country now that it was difficult to see the necessity for the nurse-anaesthetist. Every surgeon, anaesthetist, and nurse must on occasion make a mistake, but provided reasonable care and skill were employed in the performance of the duty no action for negligence should lie. In nearly every hospital the care of swabs was regarded as the most vital duty of the theatre sister. Generally speaking, the surgeon trusted to responsible nurses to account for every swab, cloth, and instrument. Mistakes were more likely to happen when the surgeon and his assistants were not used to working together. The public seemed to expect greater perfection of cure in fractures than in any other condition, the reason probably being the greater ability to see what was happening. But complications might occur in cases in which every possible care had been taken. Finally, Mr. Cope appealed to lawyers who had to deal with surgical cases to take the opportunity of seeing surgical operations in progress and to learn something of the surgeon's responsibilities.

Medical Notes in Parliament

Medical Planning Commission

On June 10, Mr. ERNEST BROWN told Mr. Groves that he was aware that the British Medical Association had invited a considerable number of representative medical men and women to become members of a Medical Planning Commission whose terms of reference were: "To study wartime developments and their effects on the country's medical services both present and future" He was not aware (as was suggested in Mr. Groves's question) that the object of the Commission was "primarily to prepare evidence to be submitted to a Royal Commission." The members of this Commission were performing a useful public service in devoting part of their time to this work, and he hoped their deliberations would result in constructive suggestions which would make for an improvement in the country's medical services. He declined to arrange with the Central Medical War Committee that the services of these doctors should be more usefully employed in the interests of the State.

Survey of Social Insurance

On June 10, Mr. GREENWOOD informed Mr. R. Morgan that he had arranged with all the Departments concerned for a comprehensive survey of existing schemes of social insurance and allied services which would be considered in due course by the Committee on Reconstruction Problems of which he was chairman. Sir William Beveridge had accepted his invitation to become chairman of an interdepartmental committee which would conduct the survey, taking into account representations received from responsible organizations and persons concerned with the problems involved.

Army Eye-shields

Capt. MARGESSON, replying to Mr. Purbrick on June 10, said that at the request of the War Office the question of affording additional protection against eye injuries in the Army had been very carefully examined by an expert committee of the Medical Research Council in the light of evidence provided by this war and the last. Several tests of various kinds of protective devices had been carried out. As a result, the committee had now recommended that no special vizor in any material was required other than the present anti-gas eye-shield.

Returned Prisoners of War: Medical Examination.—On May 27 Mr. LAW informed Mr. Lewis that details were now being worked out of a scheme by which all returned prisoners of war would be medically examined, and appropriate medical treatment made available to those in need of it. Arrangements for the rehabilitation, under medical supervision, of disabled prisoners were being made by the Minister of Pensions and Minister of Health.

Fracture Treatment.—Mr. BROWN stated on May 29 that hospital authorities were informed by circulars of April 24 of the inclusion in the Emergency Hospital Scheme of fracture cases occurring among industrial workers and civil defence workers. Further details of the arrangements for treating these cases, whether occurring among the workers referred to or among other classes included in the emergency scheme, were contained in a circular to be issued in a few days. Copies would be sent to bodies known to be interested in this subject.

Retirement of Prison Doctors.—Mr. ROBERT MORGAN asked on May 29 whether the Home Secretary knew that certain prison doctors, irrespective of their capabilities or willingness, were being retired under peacetime regulations. Mr. H. MORRISON replied that the regulations relating to retirement of prison medical officers were the same as those relating to other Government servants. They gave discretion to retain an officer owing to war conditions. That the officer did not wish to retire was not by itself a reason for an extension.

Unregistered Insured Persons.—Mr. ERNEST BROWN, on June 10, informed Mr. Groves that he was unable to state the number of insured persons who failed to register with a medical practitioner in the past year. The total amount payable to insurance doctors for any year was determined after consultation with the Government Actuary and was based on his estimate of the total number of persons entitled to medical benefit on the average during that year without reference to the question whether they had selected doctors or not. Medical men therefore did not suffer financially as a consequence of non-registration.

Nervous Shock of a "Commotional Character."—Mr. WATKINS, on June 10, asked the Minister of Pensions if he would define the term "nervous shock of a commotional character," used by his Department in connection with the compensation payable under the Personal Injuries (Civilians) Scheme. Sir WALTER WOMERSLEY said: The term "nervous shock of a commotional character" as used by his Department referred to nervous shock resulting directly from physical violence, including concussion, blast, or burial.

Notes in Brief

Statistics as to the death rate do not distinguish between evacuated children and native children. All the evidence available, however, goes to show that, in general, evacuation has had a beneficial effect on children's health. Mr. Brown has no information to suggest that the accident rate among evacuated children was higher than among other children

Universities and Colleges

UNIVERSITY OF OXFORD

The following medical degrees were conferred in Convocation on June 7:

D.M.—J. E. G. Pearson; R. D. Harding (preceded by B.M.).

UNIVERSITY OF CAMBRIDGE

At a Congregation held on June 7 the degree of M.D. was conferred on J. O. Poynton.

Diploma in Medical Radiology and Electrology

The Committee for Medical Radiology and Electrology has reported to the following effect: On the representation of the Director-General A.M.S., that the discontinuation of the diploma (D.M.R.E.) in 1941 would seriously affect the training of radiologists for service with the R.A.M.C., the University continued the examinations after October 31 last. However, only eight candidates attended the course for the year 1940-1, and the deficit for that year will be about £400. Since there will be no oversea candidates, and newly qualified men are liable to be called up, the committee, with great regret, recommends that the diploma be discontinued as soon as possible, and that no examination for it be held after October 31, 1942. The Faculty Board of Medicine has approved this report of the committee.

UNIVERSITY OF ABERDEEN

The summer graduation ceremony has been fixed for Thursday, July 10.

SOCIETY OF APOTHECARIES OF LONDON

The following candidates have passed in the subjects indicated:

SURGERY.—R. M. Ellison, A. L. H. Smith.

MEDICINE.—R. M. Ellison, S. G. L. Klein, N. A. St. C. Marley, G. H. Miles, W. H. Morgan, G. M. Pearson, O. Sookias, W. J. U Tin.

FORENSIC MEDICINE.—R. M. Ellison, S. G. L. Klein, N. A. St. C. Marley, G. H. Miles, W. H. Morgan, G. M. Pearson, O. Sookias, W. J. U Tin.

MIDWIFERY.—R. M. Ellison, W. H. Morgan.

The diploma of the Society has been granted to R. M. Ellison, S. G. L. Klein, N. A. St. C. Marley, G. H. Miles, W. H. Morgan, A. L. H. Smith, O. Sookias, and W. J. U Tin.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 17.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for (a) England and Wales (London included) (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of *Births and Deaths, and of Deaths recorded under each infectious disease*, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	1941 (b)	1941 (c)	1941 (d)	1941 (e)	1940 (Corresponding Week) (a)	1940 (b)	1940 (c)	1940 (d)	1940 (e)

Rate per 1,000 total births (including stillborn)			47						41	

* Includes primary form in figures for England and Wales, London (administrative county), and Northern Ireland.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The returns for the week under review showed a slight rise in the incidence of the common infectious diseases, with the exception of measles in England and Wales and cerebrospinal fever in Scotland.

Scarlet Fever

The 1,153 notifications of scarlet fever in England and Wales were 141 in excess of those for the preceding week. The highest rise occurred in Lancaster, where the cases increased from 132 to 190; the increase was generally distributed throughout the county. In Scotland 152 cases were notified, an increase of 10. A third of the total cases were contributed by the two cities of Edinburgh, 20, and Glasgow, 28.

Dysentery

The notifications of dysentery in England and Wales numbered 77, an increase of 5. The largest of the new local outbreaks was in Uttoxeter U.D., Staffordshire, with 11 cases. In Lancaster, Whiston R.D., 8 further cases were recorded during the week. There were 9 in London, 6 being in Wandsworth. Of the 8 cases reported from Yorks, West Riding, 4 were contributed by Bradford C.B. and 3 by Wakefield C.B. In Scotland 43 cases of dysentery were notified, 11 more than in the previous week.

Cerebrospinal Fever

An increase of 18 cases occurred in the notifications of cerebrospinal fever in England and Wales, after the sharp fall in the incidence during the preceding week. In Cheshire the cases rose from 12 to 20, and in Lancashire from 42 to 52. In the former the cases were scattered throughout the county, but in the latter the increase was contributed by Liverpool C.B., where the figures rose from 7 to 18. In Scotland 55 cases were reported, a decrease of 10. Glasgow, with 13 cases, had one-quarter of the total incidence.

Diphtheria

The notifications of diphtheria during the week in England and Wales were 926—68 above the total for the previous week. Lancaster and Staffordshire had the largest increases. The figures rose from 129 to 204 in Lancaster, and, as with scarlet fever, the disease was widespread; no district had a heavy attack. The relatively large increase in the notifications of Staffordshire, from 25 to 67, marked the highest level reached this year in that county. The increase was due to an outbreak in Seisdon R.D., where 38 cases were recorded during the week, the first occurring in this area for three months. In Scotland notifications amounted to 191, an increase of 20. The increase was fairly general throughout the country.

Measles

The number of cases of measles notified in England and Wales was 11,909, a decrease of 84 compared with the preceding week. Several counties have recorded an increasing prevalence during the past three weeks. Probably the most noteworthy are those of the rural districts of Norfolk, Suffolk, and Sussex. The number notified during the last three weeks in East Sussex, Uckfield R.D., was 48, 79, and 175; and in West Sussex, Chanctonbury R.D., 8, 13, and 60. A considerable increase in the notifications of measles in Scotland, from 96 to 151, was reported following the large decrease recorded in the preceding week. The experience of Glasgow was mainly responsible for the increased number.

Whooping-cough

The number of cases of whooping-cough in England and Wales has been remarkably constant during the past three weeks, the notifications being 4,088, 4,081, and 4,086. The totals recorded for the counties have shown some fairly sharp variations. Notifications in Warwickshire have been halved in this period, due mainly to the experience of Birmingham C.B., where the figure has fallen from 136 to 67. No consistent increase has been recorded for any county. A rise of 30 was

reported from Scotland, where Glasgow dominates the returns, accounting for 415 of the 521 cases. The highest increase was shown by Dundee from 9 to 27.

Typhus Fever

Following the outbreak of typhus fever in the Carrowmere district of West Clare, Eire, 10 actual cases and 34 contacts have been removed to the isolation hospital. Two patients have died. The outbreak is centred round about a dozen houses, and it has been proposed that these hovels should be burned down.

Medical News

Dr. Karl Landsteiner, of the Rockefeller Institute for Medical Research, New York, famous for his work on blood grouping and the specificity of serological reactions, has been elected a Foreign Member of the Royal Society.

A general meeting of the Medical Society for the Study of Venereal Diseases will be held at 11, Chandos Street, W., on Tuesday, June 24, at 2.30 p.m., when Dr. I. N. Orpwood Price will give an address on "The necessity of the clinician making the best use of laboratory facilities in the diagnosis of venereal diseases and simple methods of doing so."

A Chadwick Public Lecture on "The Interrelation of Man and Fungus in Health and Disease" will be delivered by Mr. J. Ramsbottom, D.Sc., at the Chelsea Physic Garden, Swan Walk, S.W., on Thursday, June 19, at 4 p.m.

The Long Fox Memorial Lecture will be delivered by Dr. H. H. Carleton, F.R.C.P., at 8.30 p.m., on Tuesday, June 24, in the Wills Physics Theatre, Bristol University. Subject: "The Methods of Science."

A lecture entitled "The Nature of the Self" will be delivered before the British Institute of Philosophy by Prof. H. H. Price of New College, Oxford, at University Hall, 14, Gordon Square, London, on Friday, June 20, at 5 p.m. Tickets can be obtained on application to the Director of Studies at 14, Gordon Square, W.C.1.

Two papers on Navy and Air Force Welfare will be read at the Royal Society of Arts, John Adam Street, Adelphi, W.C., on Wednesday, June 18, at 2.30 p.m., by Captain R. W. Blacklock, R.N., Personal Services Department, Admiralty, and Group Captain F. C. Halahan, Personal Services Department, Air Ministry.

Until further notice the House and Library of the Royal Society of Medicine will open at 9.30 a.m. and close at 6.30 p.m.

The June number of the *Proceedings* of the Royal Society of Medicine will contain in the Section of Medicine a discussion on "The Nature and Treatment of the Effort Syndrome" by Dr. H. J. Starling, Dr. Paul Wood, and Dr. Maxwell Jones, and in the Section of Psychiatry a paper by Dr. Aubrey Lewis on "Psychiatric Aspects of Effort Syndrome." These two reports will be issued as a combined reprint at 1s. a copy, post free. Early application should be made to the Editorial Office, 1, Wimpole Street, W.1.

The issues of the *Schweizerische Medizinische Wochenschrift* for March 15 and 22 are dedicated to Dr. W. R. Hess, professor of physiology at Zurich, on the occasion of his sixtieth birthday.

The Ministry of Food, on the advice of its Food Rationing (Special Diets) Advisory Committee, has decided that extra supplies of cheese will not be available to diabetics. It is held that the two extra meat and two extra butter or margarine rations instead of sugar make an adequate diet possible for all cases of diabetes.

It has been publicly announced that the "fortified" white loaf—bread reinforced with vitamin B_1 and calcium—will not be on sale for some time to come. A technical breakdown in the manufacture of vitamin B_1 has delayed distribution.

Dr. John O'Hara, medical practitioner, Stanhope, has received an expression of commendation for brave conduct in tendering services on the occasion of a serious lorry accident.

Dr. E. Ellan has been appointed an Honorary Sheriff-Substitute at Elgin of the Sheriffdom of Elgin, Nairn, and Inverness.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London*; SECRETARY, *Medisecra Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Post-herpetic Neuralgia

Dr. C. S. SHEAHAN (Doncaster) writes: I was interested in the note on this subject (June 7, p. 876), for recently I have had two cases of severe neuralgia following herpes zoster. One patient, a man of 60, had a large crop of cervical herpes. He was left with severe neuralgia for five months. I gave him the usual analgesics, tonics, and vitamin concentrates, eventually resorting to electrotherapeutics, which, though affording temporary relief, tended to aggregate the condition. Whether or not the injection of pituitrin 0.5 c.cm. b.i.d. during the attack diminishes the possibility of post-herpetic neuralgia I don't know, but think it is worthy of trial for this troublesome condition.

Income Tax

Depreciation of Leasehold, etc.

"D.R." inquires what deduction should be made for depreciation of a 34-year lease or on the value of a practice.

*** No allowance is due as depreciation is allowable only in respect of "plant and machinery." The "loss" referred to in Sec. 34 of the Income Tax Act, 1918, is a general loss on the business or practice, i.e., the amount by which the gross earnings are less than the allowable expenses.

LETTERS, NOTES, ETC.

Deferment of Call-up of Dispensers

Mr. HUGH M. LINSTEAD (Secretary, Central Pharmaceutical War Committee) writes: Men whose age for the purpose of military service is under 35, and who were classified as dispensers when they registered under the National Service (Armed Forces) Acts, may, in exceptional circumstances, secure deferment of call-up. By arrangement with the Ministry of Health and the Ministry of Labour such applications will be considered by the Central Pharmaceutical War Committee. They should be addressed to the Secretary, the Ministry of Health, Division 1, B, Whitehall, London, S.W.1, so that they are received not later than July 1, 1941.

Maternal Expectancy

Dr. J. R. BENTLEY writes: In view of recent remarks in the *British Medical Journal* on certification, the following true episode may add to the lighter side of the discussion. *Scene*—The office of the Medical Officer of Health in a Rural Area. *Time*—10.15, on the day after the "couponization" of clothing came into force. *Very Expectant Mother*—"I want a certificate to buy material for diapers for my baby due next month."

Rapid Identification of Cl. welchii: Corrigenda

In Miss Nancy J. Hayward's paper on the rapid identification of *Cl. welchii* by the Nagler reaction (*Journal*, May 31) four serious errors occur, due to the loss of the author's corrected proofs in a recent air raid. These errors are: (1) page 812, under the heading Modified Brewer's Medium, "agar and 0.01% sodium thioglycollate," which should read "agar and 0.1% sodium thioglycollate"; (2) page 812, Table II, column 6, "F + T, *Art*," which should read *F + A, Aer*"; (3) page 812, subscript to Table II, "T = 0.01% sodium thioglycollate," which should read "T = 0.1% sodium thioglycollate"; and (4) page 814, line 20, "the finding of Cook," which should read "the finding of *Crook*."

Dr. J. D. ROLLESTON (London, W.8) writes: I regret that the "slight error" in connection with the date of the International Congress of the History of Medicine held in London was wrongly attributed by me (*Journal*, June 7, p. 874) to you instead of to the *Lancet* in its issue of May 31, p. 703.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JUNE 14 1941

CERTIFICATES FOR EXTRA MILK

We have received a number of criticisms (some of which have been published in these columns) of the certificates which doctors are now asked to sign to secure additional milk for those of their patients who are suffering from certain defined conditions. The letter we publish at page 80 from a provincial food office to a local doctor so misrepresents the steps taken by the B.M.A. in this matter that the following statement is called for.

The first official intimation the B.M.A. received that the Ministry of Food intended to restrict the general consumption of milk was contained in a letter from the Ministry dated April 3, 1941, which stated that the restriction would begin on April 13 (ten days later), but that, following the advice of the Special Diets Committee of the Medical Research Council, special provision would be made for persons suffering from (*a*) active tuberculosis of all types and of all organized tissues; (*b*) silicosis; (*c*) conditions in which the patient is unable to swallow solid food by reason of an affection of the mouth, throat, or gullet; (*d*) gastric, duodenal, or anastomotic ulcer; (*e*) illnesses characterized by high and prolonged fever; (*f*) post-operative conditions after major operations. It further stated that the restriction would be promulgated by an Order to be "issued within the next few days," and would provide in a schedule a prescribed form of medical certificate. While it was indicated that the certificate would be handed by the doctor to the householder for transmission to the dairyman, it was not made clear that it would divulge the exact nature of the patient's illness. The letter concluded by saying that "notices for the use of the medical press would be issued shortly, but it was thought the B.M.A. would wish to be advised before these were issued"—that is, less than ten days before the restriction was to come into force. The Secretary of the B.M.A. telegraphed for copies of the Order and the certificate, and the Ministry, on April 17, supplied stencilled copies, as printed ones "were not yet available."

The Council of the B.M.A., at a meeting on April 23, had before it both the Ministry's Order and a copy of the medical certificate, and in a letter to the Ministry dated April 29 the Secretary made the following observations and criticisms on behalf of the Council: (1) The list of diseases was too rigid; doctors should be allowed in exceptional circumstances and under appropriate safeguards to issue a certificate for additional milk for persons under their care. Further, there were people without specific diseases who were eligible. (2) Application by the doctor at the Food Office for certificates placed an unnecessary burden on him. (3) The disclosure of the particular disease might prove embarrassing, and it was unfortunate that the dairyman had to be informed of the nature of the disease. (4) It was particularly unfortunate that the Association was not given an opportunity before the Order was issued to express its views, representing as it did the majority of practising doctors in the country.

Briefly the Ministry's very full reply to these criticisms, dated May 3, was as follows:

1. To make the scheme effective the circumstances in which the additional supply of milk should be allowed would need to be rigidly prescribed, otherwise there would be no effective control. The Special Diets Committee had agreed that it was desirable, in order to prevent abuse of the concession and to relieve the doctor of the need for making the decision whether the full allowance was essential or merely desirable, that the diseases should be defined as precisely as possible.

2. The arrangement that doctors should obtain certificates from the local Food Offices was designed to simplify the working of the scheme; it was expected that they would obtain a supply to be used as and when required.

3 The handing of the certificate to the dairyman was again directed by the desire on the part of the Ministry to make the procedure as simple as possible. An alternative method—namely, that the doctor should hand the certificate to the local Food Office—might lead to delay. "The Ministry believes that there must be several cases in which a certificate specifying the nature of the disease is handed to the patient for transmission to a third party."

4 The Ministry's letter of April 3, in which the scheme was "fairly fully described," was sent to the Association within two or three days of receiving the advice of the Special Diets Committee: "it was regrettably impossible to give any further notice of contemplated arrangements."

On May 28 the Secretary of the B.M.A. sent the following letter to the Ministry.

Letter from B.M.A. to Ministry of Food

Dear Sir, May 28, 1941.

I have to thank you for your letter of May 3 concerning the Sale of Milk (Restriction) Order, 1941. Before sending you this reply I have discussed the subject further with the appropriate committee of the Council and I am instructed to submit to you the following observations and recommendations for your early consideration.

List of Diseases

(a) Active tuberculosis of all types and of all organized tissues.

The committee is at a loss to know what is intended by the words "organized tissues"; presumably it means organs. It suggested that "active tuberculosis of all types" is sufficiently comprehensive.

(b) Silicosis

This was accepted.

(c) Conditions in which the patient is unable to swallow solid food by reason of an affection of the mouth, throat, or gullet.

The committee considers that there are many other conditions which would cause interference with swallowing—for example, myasthenia gravis, progressive bulbar palsy, and certain mental states. The committee recommends the following:

"Affection of the mouth, throat, or gullet, or organic nervous disorder causing interference with swallowing."

(d) Gastric, duodenal, or anastomotic ulcer.

The committee recommends the addition of chronic dysentery and ulcerative colitis.

(e) Illnesses characterized by high and prolonged fever.

This was accepted.

(f) Post-operative conditions after major operations.

The committee makes the following observations: (1) Most major operations take place in institutions, which are not affected by the Order. (2) In most cases extra milk is necessary only for the first few days, and if the patient is not in an institution the extra milk might well be provided by other members of his family.

If the heading is retained it is suggested that a time limit of one month should be imposed.

(*g*) The committee considers that acute nephritis and advanced stages of malignant diseases should be added to the list.

Procedure

The committee is glad to have your assurance that the medical practitioner may obtain a supply of certificate forms from the local Food Office for use as and when required.

The committee considers it most undesirable that the certificate should be given to the dairyman. It recommends that the certificate should be sent by the practitioner to the medical officer of health, who should issue an authority to the dairyman to supply the extra milk. The certificates should be sent in "business reply" envelopes, supplies of which should be obtainable with the certificate forms from the Food Office.

Although the certificate contains a space in which the practitioner is to insert the period for which the extra milk is necessary, the committee suggests that a time limit for the validity of the certificate should be imposed and it recommends a period of at least two months.

With regard to instruction (A) on the back of the certificate, it is presumed that all that is required is that the practitioner's diagnosis should be sufficiently clear to enable the medical officer of health, acting as agent for the Ministry of Food, to identify the category. The committee therefore suggests that it is unnecessary for the practitioner to waste the time involved in writing the full descriptions indicated in the examples given. It recommends that an entry such as " (C) Cancer of the oesophagus " is sufficient.

Debilitated Children

The committee regrets the absence of provision for the supply of extra milk for certain groups of undernourished children of school age. Children at State-aided schools who are eligible to receive milk under the milk-in-schools scheme receive it while they attend school but do not receive it if they are too ill to attend. If they are ill it is all the more necessary for them to have the milk, and the committee considers that their position should be recognized either under the Sale of Milk (Restriction) Order or in some other way. It is not always possible for other members of the child's family to allocate a sufficient share of their available milk. The committee suggests that a simple way of meeting the position would be to allow the mother or other relative to go to the school to fetch the child's milk.

The other group of children for whom the committee considers some provision ought to be made consists of the undernourished children attending private schools. It is not now a question of ability or inability to pay for extra milk, and the committee considers that the undernourished child in a private school should be accorded the same treatment as children attending State-aided schools. It suggests that an extra supply of milk should be authorized on the certificate of a medical practitioner that the child is undernourished.

Distribution of Milk

While, the committee appreciates the importance at the present time of restricting the consumption of milk, it requests me to draw your attention to its opinion that the distribution is very unequal and that the method adopted by the Ministry to reduce consumption has not removed the inequalities. It will be remembered that earlier in the winter the Minister appealed to the public to reduce their consumption of milk. Many people did so, others did not. Thus, as a result of the selection of the first week in March as the basic week, some people are suffering a reduction in supplies which they had already reduced to a minimum, while other people who had made no voluntary reduction suffer very little inconvenience. The committee believes that the only way to secure equality is to establish a basic ration per person which should not be subject to any reduction. In the absence of information on the supplies of milk available in the country both now and for next winter it is, of course, impossible to suggest a basic ration, but the committee wishes me to convey to you its opinion that on medical grounds all who wish should be able to purchase 1/2 pint of milk a day. It also believes that if the Minister would reduce the maximum daily amount that any person may receive without a medical certificate to 1 pint a day the saving would enable him to assure a basic ration of 1/2 pint to all who wish to purchase that quantity.

I shall be glad to have your views on these suggestions at your early convenience.

Yours faithfully,
(Signed) G. C. ANDERSON,
Secretary.

GENERAL MEDICAL COUNCIL

DISCIPLINARY INQUIRIES

(Concluded)

Convictions for Drunkenness and Cognate Offences

PHILIP ARDERN ASHCROFT, registered as of Littleborough, Manchester, was summoned on the charge that in February, 1939, he had been convicted of driving a motor-car whilst under the influence of drink. There was a similar conviction in 1933. Dr. Ashcroft apologized for the circumstances which had brought about these convictions, stated that he was now a teetotaller, and put in a number of testimonials. The Council did not see fit to erase the name.

PATRICK KENNEDY, registered as of South Harrow, appeared on three convictions, one in 1931 of being in charge of a car when under the influence of drink, one in 1939 of being drunk and incapable, and one in 1940 of being under the influence of drink to such an extent as to be incapable of having control of a motor-car. Dr. Kennedy said that he was sorry these events had happened, and he put in certain testimonials. The Council postponed judgment on the usual conditions until May, 1943, but required Dr. Kennedy to appear in May, 1942, and to furnish testimonials as to his conduct in the interval.

Other Convictions

MAURICE PERLMAN, registered as of Market Place, Chippenham, appeared on a conviction of having obtained small sums of money by false pretences. He was placed on probation for twelve months.

SADIC MIKHAIL, registered as of Alderney Road, Mile End, London, appeared on a conviction of having used insulting words at the entrance to a public shelter during an alert. It was stated that he had refused to move at the request of a constable. Dr. Mikhail said he was a doctor appointed to the shelter and to the first-aid post. He was waiting at the entrance to the shelter merely to get his eyes accustomed to the darkness when the constable told him to get out and pushed him. He denied having used insulting words. The Council did not see fit to erase the name.

Adultery and Professional Relationship

The Council considered the case of RICHARD CHRISTOPHER HOWARD, registered as of 104, Harley Street, who appeared on the charge of having committed adultery with Edith Ellaline Hart-Davis, a married woman, of which adultery he had been found guilty by decree of the Divorce Court, and that he had stood in professional relationship with the said Mrs. Hart-Davis from November, 1934, until July, 1938, and with her husband from November, 1934, until December, 1937. The case was brought before the Council by Mr. Hart-Davis, who was represented by Mr. Woolfe, solicitor.

Dr. Howard admitted that he was in professional attendance during the periods mentioned, but he strongly denied having committed adultery. In reply to the President, who pointed out that the Divorce Court had found him guilty of adultery, Dr. Howard said that it was possible to care quite a lot for a person without committing adultery, that sometimes the position of anybody who decided, rightly or wrongly, that it was his job to help two unhappy people became impossible, and that it was in certain circumstances out of the question for a doctor who believed in the Hippocratic oath and was not willing to betray professional confidences to defend himself adequately.

The Council found that Dr. Howard had been guilty of infamous conduct in a professional respect, and instructed the registrar to erase his name.

JAMES LESLIE HILL, registered as of Chepstow Road, Newport, Mon., appeared before the Council on the charge of having committed adultery with Gwenda Margaret Watson, a married woman, of which adultery he had been found guilty by decree of the Divorce Court, and that he had stood in professional relationship with the said Mrs. Watson at all material times. Dr. Hill was defended by Mr. Oswald Hempson, solicitor.

Dr. Hill in the witness box admitted that he had been properly found guilty of adultery, but he claimed that adultery had taken place before either the lady or her husband was his patient. Mr. Watson had become his insurance patient in October, 1937, and the first attendance on Mrs. Watson was in July, 1938, but misconduct was committed in August, 1937.

Mr. Hempson pointed out that Dr. Hill had already been punished severely, having had to sell his practice at far below its value, and to pay £750 damages. He had now married Mrs. Watson, and they were living happily together. Adultery took place before either of these people became his patient, and in fact he was not the lady's doctor until twelve months after the association began.

The Council judged Dr. Hill to have been guilty of infamous conduct in a professional respect, and instructed that his name be erased.

Dental Cases

Two dentists were erased from the *Dentists Register* on the recommendation of the Dental Board, namely, James Harold Hill, registered as of Lea Bridge Road, London, E., who had been convicted of larceny and of obtaining credit by fraud, and John Harold Smith, registered as of Clay Cross, who was found to have employed as agent for the purpose of procuring patients a certain unregistered person.

In a further case, that of William Hope, registered as of Bristol Road, S.W., who had been convicted of a misdemeanour (which he strongly denied), the Council, after hearing the respondent, decided not to accept the Dental Board's recommendation, and did not see fit to instruct the Registrar to erase the name.

MEDICAL WAR RELIEF FUND

SEVENTEENTH LIST

Previously acknowledged £24,246 10s. 7d. and £100 3½% Conversion Stock

Individual Subscriptions

£5 5s.—Dr. D. (Qu.), Leicester, Dr. I. M. Dyer, Newport, Dr. P. [illegible], A. H. Knighton, Wonersh, Dr. G. Shearer, S. Yorks, Dr. H. [illegible], Friar Oaks.

£5.—Dr. A. McK. Fleming, Gibraltar, Dr. R. Lang, Gibraltar.

MEDICAL INSURANCE AGENCY

The annual meeting of the Medical Insurance Agency was held on May 26, Sir Humphry Rolleston in the chair. The report of the Committee of Management, together with the audited accounts and balance sheet for 1940, were submitted and adopted. The effects of the war naturally caused a serious falling off in the volume of business and in the surplus profits available for the medical charities, but it was felt that the report was, in the circumstances, surprisingly good, and a vote of appreciation was minuted to the staff for their untiring efforts. The meeting decided to reserve £200, approximately, to meet E.P.D. for 1939, and £375 for a similar purpose in respect of 1940. After a further reserve towards income tax for 1940, there remained a balance of £2,250, in round figures, to satisfy "covenants" entered into with the charities of a total of £2,500. It was decided to pay nine-tenths of the covenanted sums—namely, £1,800 to the Royal Medical Benevolent Fund, and £450 to Epsom College Foundation. In each case the charity will recover an equal amount as a result of the covenant, so that they will in fact receive double these amounts. It was also decided to allocate £514 to increase the endowment of the Squire Sprigge (Girls' Scholarships) Fund. Dame Barrie Lambert, Dr. G. C. Anderson, Dr. J. W. Bone, Dr. John d'Ewart, and Dr. Henry Robinson were re-elected members of the Committee of Management for a further period of three years. The meeting terminated with a vote of thanks to Sir Humphry Rolleston.

Correspondence

Milk Certificates

SIR,—I would ask you to publish the following correspondence for the information of other members of the B.M.A., and also the medical members of Parliament. The discrepancy between the Parliamentary reply and the letter from the Government Department appears to need some clarification.—I am, etc.,

Norwich, May 28. B. R. BRAMWELL, M.D., M.R.C.P.

Copy of Letter from Dr. B. R. Bramwell, Norwich, to Local Food Executive Officer

Sale of Milk Restriction Order, 1941—Milk Certificate

Dear Sir,—I beg to bring to your notice a requirement of this form which I consider to be incompatible with professional ethics—namely, that under (2) of the medical certificate I am required to disclose to the milkman and all and sundry having access to the certificate that a patient of mine is suffering from tuberculosis. Such matters are personal to myself and the patient, except in so far as it is my statutory duty to notify, in confidence, to the M.O.H.

It is my intention, therefore, to use my discretion in completing this form until instructed to the contrary. Under no circumstances do I feel called upon to inform my patient and the milkman (both of whom may be blissfully in ignorance of the diagnosis) that a patient of mine is suffering from cancer or tuberculosis, such knowledge being frequently detrimental to the former and certainly nothing to do with the latter.—Yours faithfully,

April 18. (Signed) B. R. BRAMWELL, M.D., M.R.C.P.

Copy of Letter from Norwich Food Control Committee to Dr. Bramwell

Dear Sir,—Further to my letter of the 9th instant, the Ministry of Food have now informed me as follows:

"We have had a number of representations on this subject, but so far no objection to the procedure which we have outlined has been lodged by the British Medical Association. The B.M.A. was given full particulars of the scheme at the outset, and unless and until we hear from them that there are objections on the grounds of etiquette or otherwise, I do not think we shall change the existing arrangements."—Yours faithfully,

May 27. (Signed) BERNARD STORY, Food Executive Officer.

Copy of Letter from Dr. Bramwell to Local Food Executive Officer

Dear Sir,—I am greatly obliged to you for your letters on this subject. The communication from the Ministry of Food, quoted in your letter of the 27th, does not seem to be in accord with page 764 of the *B.M.J.* of May 17, 1941, and marked in ink, "Medical Notes in Parliament," which I enclose.

I might add that letters have appeared in the *B.M.J.* on the subject, and I am at a loss to understand any body of medical men agreeing to such a form being passed for use. Nor does the reply of Major Lloyd George indicate that the B.M.A. did in fact pass it. If, on the other hand, the B.M.A. did pass the form, then it certainly does not represent myself, though I am a member.

It is my intention to send to the B.M.A. copies of my letter to you and the Ministry's communication to you on the matter.—Yours faithfully,

May 28. (Signed) B. R. BRAMWELL.

* * This matter is referred to at page 77 of the *Supplement*.—ED., *B.M.J.*

Increase in Private Fees

SIR,—There seems to be a spate of letters to the *B.M.J.* giving an impression that doctors are mainly concerned with the matter of remuneration. I agree with the opinions expressed by Dr. E. D. Granger (*Supplement*, May 31, p. 71). I also think that, provided the Government would treat requests (for increased wages) from other sources in a similar manner, they would be justified in not raising the capitation fee at present. With regard to the hardships of doctors in reception areas; granted we have to see many evacuees for nothing and panel patients who have lost their medical cards, sign milk forms, etc. We must admit that our environment more than compensates for this. My pet grouse is that the payment for attending unaccompanied evacuated children is very belated; but perhaps it could be arranged to coincide with the next demand for income tax.—I am, etc.,

Kennington, near Oxford, June 1. G. D. SHANN.

Free Choice of Doctor

SIR,—Dr. Marwood's article (*Supplement*, May 17, p. 66) is written with almost disarming fairness, but it cannot escape criticism. He begins by stating that "State Medical Service . . . cannot come too soon provided the stultifying influence of civil service methods is avoided," and that "a multitude of problems have to be tackled before conception is translated into practice." From the problems to be tackled he selects free choice of doctor. I have always assumed that this term is intended to mean the patient's right to change his doctor if he is not satisfied with him, but it has also come to be used as an easily expressed symbol of the existing conditions of general practice as opposed to a State service. It is proposed to change our existing system of practice for one that admittedly requires much reform. Why do this before we have found that it is not possible so to reform general practice that it may be improved in the way that is wanted? We should at least insist that civil service be reformed in the way Dr. Marwood very properly suggests before we think of allowing the practice of medicine to be submerged into it. I cannot see that we should be called upon to restrict free choice for the sake of this State service; rather should not the State, if it does take control, endeavour to find some means of satisfying the public desire for maintaining the valuable existing relationship between doctor and patient?

Dr. Marwood believes that it is possible to substitute faith in the profession as a whole for faith in the individual doctor, and cites in support the case of the hospital. Surely there are here two acts of faith: the one in the personal friend, the family doctor; the other in a body of selected specialists from which the patient seeks advice for some special illness and generally at the request or with the consent of the general practitioner. I do not understand why "insistence on the preservation of free choice of doctor" should militate against the effective working of a State Medical Service with its vaunted "manifold advantages of early diagnosis and prompt treatment divorced from financial anxiety." Surely these advantages are exactly what National Health Insurance provides, and with them that free choice of doctor which apparently a State Medical Service cannot give.

The waste of mileage and time in a system whereby several doctors are visiting the same district and even the same street on any one day is certainly a serious matter, though it is one that may, to a very considerable extent, be overcome by that reform of general practice which we must consider now, before we allow ourselves to be included in a State service. Among the reforms proposed are larger partnerships, some system of local voluntary groups or co-operation which would give us easier holidays and days off, easier attendance at post-graduate courses, and better division of work. We also need

more hospital beds for the G.P. and better pathological and consultant service under National Health Insurance; we should also participate in public health work.—I am, etc.,

CHARLES E. S. FLEMMING.

Bath, May 22.

Increased Health Insurance Benefits

SIR,—The statements in Parliament on increased benefits to insured patients with an intimation that a further half-million of the population is to acquire insured status must surely demand an immediate reconsideration of the remuneration for insurance practitioners. Up to this moment most of them have been content to accept the advice that, at a difficult moment in the nation's fortunes, no effort should be made to increase those difficulties, but with sweeping change in benefits and in the scope of the scheme this consideration can no longer hold.

The average insurance practitioner has lost a large proportion of his list to the Forces, and those in bombed areas to the country. In spite of this he must keep going a similar establishment at increased cost of both material and personnel, and he has now lost another percentage of his private work to the ranks of the insured. Added to this the voluntary services rendered in A.R.P. work—services which no one grudges but which must be taken into consideration by those who act for the profession—have reduced his available time. It would seem, therefore, that the time has come to call for an increase in the capitation fee. It has long been deserved, delayed too long, perhaps, owing to the representations of the ruling bodies, but has now reached the stage of a crying necessity.—I am, etc.,

W. LEES TEMPLETON.

Highgate, N.6, May 23.

State Medical Service

SIR,—The enthusiastic advocates of a State Medical Service appear to be direct spiritual descendants of Pygmalion, for they have fashioned an image with which they have fallen in love. How far their idealized creation would differ from the reality can easily be visualised by those who are familiar with the results of many approaches to the Minister of Health on such matters as an increase in the N.H.I. capitation fee. However reasonable the request has been, and however well supported by carefully accumulated evidence, it has always met with an arbitrary refusal. Why so many members of the profession long to place themselves under the completely autocratic control of a Government Department is a mystery to me, and, I believe, to many others. Are the principles of Fascism spreading so insidiously that they are causing us unconsciously to place one of the oldest and most honourable of all professions under a dictatorship? As to the alleged inevitability of a State Medical Service, surely some of your correspondents must be tinged with Oriental fatalism. There is nothing inevitable about it, if we do not want it and do not intend to have it. Lastly, it seems that after every war there is going to be a new heaven and a new earth, even according to those who appeared to find the old ones perfectly comfortable, but experience shows that when things have settled down again the old earth at any rate (for I cannot answer for heaven) appears to jog on in much the same fashion.—I am, etc.,

W. N. MAPLE.

Hove, March 24.

SIR,—I write as a general practitioner of twenty years' experience in a London suburb. In the last few years I have often asked myself and my fellow practitioners if the practice of medicine as it is to-day is really the best we can give our fellow creatures. I feel there is room for much reform from the point of view of both the general public and the doctor, so I venture to submit a scheme of State medicine which I hope may be considered practicable. There is a fact that we medical men must never forget—we are the servants of the public and they will have the last word in deciding whether they will have a State service or not.

My two main reasons for advocating a State service are: (1) The vast majority of the public who are not insured cannot afford to have a doctor, and I see no likelihood of such prosperity arising that this position will be altered. (2) The many reforms in the last twenty years that successive Governments have made in health benefits to the nation, admirable as their intentions have been, have resulted in a very complicated system, and in the whole of this period have eventually taken work away from the general practitioner, who is often spoken of as the backbone of the profession of medicine.

In my scheme there will be three main benefits: (1) It will benefit the nation as a whole in the matter of its health by enabling the doctor to educate the public in the prevention of disease. (2) The public will have the benefit of co-ordination of treatment free from financial worry, and at the same time free choice of their own doctor without feeling that every time they want him they have to put their hand in their pocket. (3) The doctor will benefit because he will be able to treat his patient in his consulting-room, in his own bed in his hospital, and in the patient's home. He will have adequate remuneration for his work and a pension at 65 to free him from financial worry in his later years. He will get sufficient annual holiday and a period for postgraduate study. Above all, he will be free to give all his skill to his patient without the failings of competitive medicine.

A scheme of State Medical Service must be divided into two parts (1) a general practitioner's or family doctor's service: (2) a consultant ervice. For my purposes a general census of the population would be necessary. To illustrate this scheme I am taking as an example an area containing 60,000 inhabitants. No doctor would have on his list more than 3,000 patients, so that in this area there would not be more than twenty doctors. Thus the patients who lived in this area would have their own choice of twenty names. In the centre of this area a health centre would be erected. This would be a one- or two-storied building and would contain twenty consulting and twenty waiting rooms. Each consulting and waiting room would be known as a particular doctor's "chair of health." There would be a central control room where all messages would be received from patients, and each doctor would have the assistance of a nurse and secretary combined. There would be a well-equipped casualty room where all minor injuries could be attended to; an *x*-ray department; a large pharmacy staffed by fully qualified pharmacists; a pathological laboratory and bacteriologist; and a board room where meetings would be held for the management of the centre, the board consisting of the doctors, members of the public, and representatives of the Ministry of Health. Attached to the health centre there would be a nursing centre of district nurses available to visit cases as required by the doctors. In addition to the health centre in this population of 60,000 people there would be a fully equipped hospital of 200 beds. Each doctor would be allotted ten beds which would be under his care. The hospital would have a staff of house-surgeons, who would be attached to each doctor, and the resident's duties would be in the hospital, with his doctor in the health centre, and visiting patients for his doctor in emergencies and in a night service.

Secondly, the consultant service. In each area—for example, North, South, East, and West London—and in each county there would be a fully equipped consultant team—that is to say, all branches of surgery and medicine would have at their service the greatest skill available. These consultants would have their specially fitted rooms in each hospital for their work, and would be called in by the doctors, who would be able to see their patients with the consultant. When a consultant was called the doctor would work under his direction assisted by the house-surgeon. No consultants would have private patients; they would all be higher paid State servants and would be pensioned accordingly. This, no doubt, would mean that some of the most eminent men in medicine would be making great financial sacrifices, but I think they are of such a calibre that between them they could foster a scheme that would be acceptable. Their duties would also include the teaching of students, and their services for this and the enormous amount of hospital work they now do unpaid should be adequately recognized by the State.

This State scheme does not include the large Public Health Service which now exists in such a satisfactory manner. Linking these services the Ministry of Health should have an advisory council composed of representatives of the Royal Colleges of Physicians and Surgeons, consultants, public health officers, family doctors, and pharmacists. This council would be of enormous value to the State, as each branch of the service would be equally represented.

The questions whether the present system of the employer paying for some of his employees' health should continue o whether it would be better to tax everyone by a health ta

in proportion to his income I do not propose to discuss, as I think State actuaries would be able to advise on them. As regards the salaries of doctors, there could be no such thing as compensation for practices; although doctors have paid large sums for these the State in return will be giving a guaranteed income and pension. House-surgeons would be paid £200 a year, would live in hospital and have full board, and would have the opportunity of studying for consultant service, or, after an interval, to be elected to an available "chair of health." Doctors elected to a "chair" would have a minimum salary of £750 a year, rising to the maximum of £1,500 according to their years of general practice, and would be pensioned accordingly. Consultants, again according to their years of consulting practice, would have a rising scale from £750 to £2,500 and pension accordingly.

In proposing such a scheme I feel there is something to think about, something to discuss together, always keeping in mind that we doctors and consultants are the servants of the public and how we can serve them best.—I am, etc.,

London, S.W.2, May 4. R. T. BAILEY.

SIR,—I note that the Minister of Health stated recently in the House that he "did not consider the present time opportune" to increase the capitation fee, and he later amplified this by pointing out difficulties which prevented taking into account the recent rise in the cost of living and the rise in practice expenses. One may well ask when will any Minister of Health ever consider the time opportune for increasing the capitation fee? In the past twenty years I am not aware that the time has ever been opportune, though when economies were needed to balance the Budget in 1931 that was an opportune time for bringing about a temporary decrease. If the nation cannot spare a few hundred thousand a year extra for panel practice at a time when it is spending a million every two hours on the war, it is obvious that the time will never be opportune in the eyes of the Ministry until faced with the 100% resignation of all panel practitioners as an alternative. Until such time as our representatives are prepared to take drastic action we shall get nowhere.

This is the treatment accorded to panel practitioners by Ministers of Health of all parties, yet there are actually practitioners who advocate a State Medical Service, and who would entrust the whole of their practices to the Ministry. It is obvious that any such scheme would be suicidal. In a very short time the status of medical practitioners would be reduced to that of the elementary school teacher. The salary would start at £250 with a maximum of about £750.

This question of status seems to have been very largely ignored. At present it is usual for a doctor to live in one of the best houses in his neighbourhood, to drive a respectable car, to send his children to public schools, and otherwise to enjoy a fairly high social status. All this requires a reasonably good income, and it is the exception for a salaried medical officer employed by the public health authorities to be as well off in this respect as his G.P. colleagues. Now this "status" is one of the G.P.'s assets: the expenses of his prominent house are recognized by the tax authorities as being necessarily incurred in maintaining the goodwill of his practice. But would such a "status" be necessary to a medical officer in a State service? There would be no goodwill to be kept up; it would not matter to the public health committee whether their medical officers turned up at the clinic in their own cars or on the municipal tram, and a municipal house would be quite adequate for them. Such considerations would be weighed up in determining what was an adequate salary, as would the fact that there would be a month's holiday with pay, a pension at 65, and other apparent attractions. The result of this loss of status would ultimately be that medicine would cease to offer the attractions of other professions such as the Law, and it would gradually pass into the hands of quite a different class of the community.—I am, etc.,

Coventry, May 17. D. MURRAY BLADON.

SIR,—With reference to Dr. B. Spearman's letter (*Supplement*, May 24, p. 70), I think that few members of the old West African Medical Staff, who formed by far the largest body of medical men employed in the Colonial Medical Service, would agree with his statement that the emoluments of the service have increased by 50%. On the contrary, their total pay and allowances have decreased, apart from the loss of valuable sources of income from private practice.

I will not enter here into the question of their loss of status and prestige, but will merely assert that it was in opposition to the wishes of the majority of the West African Medical Staff that they were absorbed into a unified Colonial Medical Service.

I enclose my card and am, etc.,

May 26. EX-W.A.M.S.

Medical Services of H.M. Forces

Appointments

ROYAL NAVY

Surgeon Lieut.-Commander A. J. Glazebrook has been placed on the Retired List.

Acting Surgeon Lieut.-Commander J. Carlton to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieut. P. S. Ludman to be Surgeon Lieutenant-Commander.

Probationary Surgeon Lieut. G. F. Adams to be Surgeon Lieutenant.

Probationary Temporary Surgeon Lieuts. T. B. Whitehead, J. Mackenzie, G. T. Allen, H. J. Bradshaw, W. A. Fyfe, L. N. Lennox, C. J. Vaughan, R. C. R. Gothen, P. L. Nicolle, V. H. Allan, R. V. Blaubaum, R. Kershaw, E. B. Riding, N. Marks, and P. R. Day to be Temporary Surgeon Lieutenants.

ARMY

Colonel (temporary Brigadier) W. H. O'Riordan, M.C., late R.A.M.C., has retired and remains employed.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonels A. C. Elliott, retired pay, W. Davis, retired pay, and A. T. Frost, O.B.E., retired pay, have reverted to the rank of Major, at their own request, whilst employed during the present emergency.

Major G. D. Jameson has been restored to the rank of Lieutenant-Colonel on reversion to retired pay.

Captain (temporary Major) R. C. Langford to be Major.

Short Service Commission.—Captain C. W. A. Hughes to take rank and precedence in his Corps and in the Army as if his appointment as Captain bore date March 31, 1941.

Short Service Commission.—Captain C. E. Watson has been placed on the half-pay list, and has retired on account ill-health

Postgraduate News

The Fellowship of Medicine announces the following courses for Final F.R.C.S. candidates: (1) Clinical demonstrations, 2 p.m., Wednesdays, July 2 to 23; (2) Revision course, daily 10 a.m., July 7 to August 1; (3) Practical Operative Surgery, Mondays, Thursdays, and Fridays, 2 p.m., July 7 to August 1; (4) Urology Course, Thursdays, 2.30 p.m., August 7 to 28.

A second wo[illegible] medical services for medical practitioners, arran[illegible] anchester in collaboration with the Association of [illegible] will be held in the medical school of the universit[illegible] June 28 and 29. The fee for the course is £1 [illegible] may be had from the director of extramural stu[illegible] ester, 13.

WEEKLY POSTGRADUATE DIARY

B[illegible] ie Road, W.—Daily, 10 a.m., Operations, Obstetrical and [illegible] 1.30 p.m., Post-mortem [illegible]e, Dr. R. Lightwood, Wed., [illegible]edical). Thurs., 2 p.m., [illegible] ration, [illegible] (Surgical), 5 p.m.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Royal Chest Hospital, City Road, E.C., Weds., 3.30 p.m. *M.R.C.P. course in Heart Diseases.*

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Neurology.—Thurs., 5 p.m. Annual general meeting. Paper by Squadron Leader Denis Williams: Electro-encephalography in Trauma to the Brain.

Section of Physical Medicine.—Fri., 4.30 p.m. Annual general meeting. Paper by Dr. P. Bauwens: Thermionic Control of Electric Currents in Electromedical Work.

Section of Ophthalmology.—Fri., 5 p.m. Annual general meeting. Paper by Mr. T. M. Tyrrell: Some Notes on Treatment of War Injuries of the Eyes.

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—Thurs., 3 p.m., Major Higham, R.A.M.C.: Head Injuries. Medical men and women in any of the Services, including civilian, will be welcomed.

PADDINGTON MEDICAL SOCIETY.—At St. Mary's Hospital, W., Tues., 8.45 p.m. Annual General Meeting, Election of Officers, etc. Dr. G. de Swiet: The Place of the Doctor in the Community of To-morrow.

VACANCIES

EXAMINING FACTORY SURGEON.—The appointment at Eastbourne (Sussex) is vacant. Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by June 17.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

BENHAM—KILNER.—On May 28, 1941, at Heyworth, near Huddersfield, George Herbert Harry Benham, M.B., M.R.C.P., to Ena May Kilner, S.R.N.

DEATH

WHITEACRE.—On May 6, 1941, R. D. Whiteacre, M.B., B.Ch. (Dublin), of 262, Devonshire Avenue, Southsea.

SOME PROBLEMS OF MINIATURE MASS RADIOGRAPHY

BY

J. V. SPARKS, M.R.C.S., L.R.C.P., D.M.R.E.

Assistant Medical Officer, X-ray Department, St. Bartholomew's Hospital; Assistant Director, X-ray Department, Brompton Hospital for Consumption

The advent of war found us unprepared not only from the point of view of military equipment but also in the seemingly insignificant means of undertaking mass radiography by the miniature method. Though the results of such methods trickled unceasingly into this country from South America, Germany, and Holland for some years before the war, not until hostilities had started was it appreciated that the method was likely to prove of the greatest value in preventing the enrolment of tuberculous subjects in the Services and in industry. It is idle to complain that we missed the opportunity of importing the necessary type of apparatus, which had carried out many thousands of such examinations in enemy and enemy-occupied territory. Let us rather take consolation in the fact that our own manufacturers have now overcome great difficulties in designing and perfecting apparatus suitable for this work.

The Royal Navy has published the results of the first 18,000 men examined by this means, and it is to be hoped the opportunity will now be taken of establishing this new method in other Services and in industry; for as the war progresses it will become of increasing importance, and without organization the demand will not be met.

While it is true that any *x*-ray plant, fluoroscopic screen, and suitable camera attachment will take a miniature radiograph, there is a vast difference between such a procedure and mass radiography by the miniature method. It must be emphasized that a special apparatus is required for mass radiography, as the machine must be capable of examining cases at the rate of 200 an hour, perhaps even of 1,500 daily. The importance of such speed was emphasized by Rear-Admiral Dudley in his report. There is no doubt that these numbers throw a great strain on the personnel and on the tube, yet this problem is such that machine design must be in alignment with all possible eventualities.

Application of Mass Radiography in War

Though from the surveys carried out by observers abroad useful information can be gleaned on the technical side, the problems to be faced in any attempt to undertake mass radiography by the miniature method in this country differ because of the larger population distributed in a larger number of independent big towns situated in close proximity to each other. The "calling up" for registration purposes, for example, might entail the *x*-ray examination of 500,000 persons within a period of twelve hours, and if each machine examined 2,000 men 250 machines would be required. The cost of these machines, even if they were available, would represent a capital outlay of £250,000 and would cover only a small fraction of the centres where registration takes place. Even if a plant were erected in each county the cost of travelling to it might far exceed the cost of the usual routine film.

The provision of facilities for carrying out miniature radiography in conjunction with the routine medical examination would also involve a large capital outlay—in the neighbourhood of £150,000—and would have the additional disadvantages of limiting the number of men examined daily and of failing to provide the necessary information at the time the medical examination was made. The examination of the young adult females who have recently registered—a most important group of persons especially prone to infection—would have supplied data of great value.

It certainly seems unlikely that any organization for dealing with such large numbers can be developed at the present time. Alternatively there are considerable possibilities of carrying out a smaller scheme that would include the sections of the fighting Services likely to be subjected to the greatest strain. By this method all men would be examined before proceeding for service abroad, and all cadets to be trained for special duties would have the benefit of this additional examination. The advantages to be gained might well be applied to this latter group immediately, using the routine examination until such time as the miniature method is available.

Application of Mass Radiography in Peacetime

It is likely that miniature radiography will play an important part in the routine medical examinations of the community after the war. There is no reason to doubt that the increased incidence of tuberculous disease that became evident after the last war may again become manifest, especially in view of the additional factor of the conditions brought about by aerial warfare. First, facilities can be provided for the examination of all men called up for military service at the age of 20, and there will be no reason why each man should not be re-examined before his discharge. These examinations will supply important information as to the incidence of chest disease in the male population at that age, and the radiographs will provide an invaluable record of the state of the lungs at that time—a record which could be referred to at will by any hospital or medical attendant should the person subsequently develop a chest complaint. Such examinations would depend on the maintenance of conscription after the war.

In civil life in this country the problem would present greater difficulties than those encountered in an undemocratic constitution. It is obvious that such methods would have to be organized and developed on voluntary lines by individual concerns. That this will be done on an increasing scale is not doubted, as it will benefit the health of the employees and be of financial interest to the employer.

Messrs. Phillips and Co. of Einthoven have in the last seven years completed an examination of 100,000 employees and their relatives; during this period the

number of days sick leave occurring annually in their company as a direct result of tuberculosis has diminished by no less than 71%, and for an expenditure of 88,000 guilders 252,000 guilders had been saved in expenses for sick pay, medical treatment, treatment in sanatoria, and pensions. The examinations have been carried out voluntarily, as they would be in this country, and were extended to include the members of the household of any of the staff, being repeated at intervals of eighteen months. No charge is made for the service.

There is little doubt that a Government Department or industrial concern might have difficulty in persuading all its employees to consent to such an examination, which might have a far-reaching effect on their employment, and some of the more suspect individuals might reasonably avoid being examined. Many months would necessarily elapse before such a scheme could become universal. A start, however, could be made by insisting that all prospective immigrants entering the country were examined; similarly, this regulation might be applied to all new applicants for the Civil Service, including post-office workers, policemen, and school-teachers. All persons returning to duty following a period of sick leave should necessarily be included. In industrial firms the examination of all new employees should be insisted on, with the result that in a few years, with periodic examinations, the incidence of tuberculosis would undoubtedly show a steady fall. This new form of *x*-ray examination would be of especial benefit to the employers in industries in which a "dust hazard" exists, as by this means any fresh applicant for employment would have his chest record made and the employer would refrain from signing on any man whose lungs showed signs of damage from previous employment. Also, in assessing individuals for life insurance many errors could by this means be avoided.

Through the kind co-operation of Messrs. Stanley Cox, Ltd., we were able to take a small series of miniature radiographs of patients attending the out-patient department of Brompton Hospital in the few days previous to the delivery of the plant to the Services. It was hoped that during this period we should be able not only to compare the miniature film with the routine radiograph but to come to some conclusions as to the type of lesions which might fail to be visualized by the former method. It is unfortunate that during the few days the apparatus was available hardly any of the patients with minimal shadows attended for their periodic routine radiograph, but some idea of the accuracy of the visualization of small areas of infiltration can be gauged from a study of the opposite lung in the cases under treatment by artificial pneumothorax (see Table).

Type of Apparatus Employed

The type of plant was essentially the duplicate of the machine used by the Royal Navy, as reported by Rear-Admiral Dudley and Commander Fitzpatrick (1941). It is fitted with a 10 kW shock-proof tube, the cooling fan of which comes into operation when the temperature rises above a certain critical temperature. The focal screen distance is 86 cm., and the screen - camera distance 76 cm. The special features include an electrically operated camera which brings the new film into position, and automatic illumination to indicate that the device by which the patient's name is photographed on the film has been effective. The latest type of Kodak film was used throughout for these examinations, and no test of speed was attempted. It was, however, obvious that owing to the neat design of the plant patients could be photographed at the rate of 4 a minute, and that it took longer to record the particulars of the patient's name and number than to carry out the radiographic procedure.

Consideration of Technique

In this country mass radiography is only at its beginning, and the few plants in operation are not yet working to capacity. The plant as supplied to the Royal Navy has on occasions achieved 220 examinations an hour.

Observers abroad give full details of their technique and the numbers examined, but provide little information of the time period over which the examinations were carried out and no details of tube life under such circumstances. This latter is of considerable importance in estimating the cost of mass examinations. There are few constant factors in the technique of other workers. In only one instance was a 6 kW tube used. Other workers have employed the 10 kW tube or the rotating anode type. The 10 kW tube used by the Royal Navy has taken 220 photographs in an hour, and it is thought unlikely that the rotating anode tube would be capable of standing up to this speed for long periods. The tube - screen distance is in all cases small in order to minimize exposure time.

The use of a stationary grid is said to improve contrast; but here, again, the grid doubles the exposure time and throws an increased strain on the tube. Nevertheless, the time of exposure is already greatly in excess of that in common use for routine radiography, being for the small patient 0.3 second without a grid. It is to be hoped that the research into the speed of the miniature film will bring about still further improvement in the time factor. Experiments into the optimum combination of screen and film have recently been reported by Stanford (1941).

Miniature radiography will naturally fail primarily in those cases in which routine radiography produces a less efficient result, notably in the large or muscular patient. In this respect Commander Fitzpatrick is to be congratulated on the uniformity of his results. It will also fail in those cases in which fluoroscopy is essential to complete the diagnosis. These cases form only a small percentage of the whole. To what extent miniature radiography will demonstrate the soft minimal lesions of tuberculous disease and the reticular shadows associated with bronchiectasis and other disease should form useful material for investigation, in conjunction with the routine film, in a chest hospital. As against this small percentage of failures, the method will bring under observation the large majority of persons with abnormal shadows in the lungs—persons who may have either indefinite physical signs or complete absence of them.

There is no question of this method acting as a substitute for normal radiography; rather should it be considered an additional means of bringing under investigation a number of symptomless persons who may subsequently be found to have abnormalities in the chest. Errors of commission will be eliminated by routine radiography and medical examination.

Viewing of Films

The problem of viewing miniature films is an important one, quite apart from their interpretation, and it is probable that they should be subdivided into three main groups—normal, abnormal, and inadequate for interpretation. The second and third groups may be found to represent about 5% of the total. A difficulty will be found in the eye-strain involved in reporting. The miniature film when projected does not form so distinct an image as the routine film, and the detail does not improve on close inspection. Though the results can be viewed at leisure one finds that after reporting 100 films in an hour a definite eye fatigue sets in. No such fatigue was noticed after viewing the same full-sized films the next day.

The comparative reports of the miniature and full-sized films (see Table) are appended without comment, as it is realized they are limited in number and not representative of the type which would be encountered in any mass survey.

Table showing Comparative Reports of Miniature and Full-sized Films

6 N = Normal.
112 ABN = Abnormal.
1 I = Indeterminate.
1 X = Errors of commission which would be corrected by routine radiography.
5 Y = Errors of omission.
22 O = Cases in which miniature radiograph suggested an abnormality without revealing all the abnormal shadows or their exact nature.

It is emphasized that the miniature films are less easy to interpret and that the sharpness of detail was not at all comparable to that obtained by the condenser set using a rotating anode tube and an exposure of one-thirtieth of a second. The image was, in fact, reminiscent of that procurable in a chest radiograph of about twenty years ago. However, as can be seen, it sufficed in a large majority of cases to give the necessary indication of the desirability of carrying out a further examination.

Protection.—It seems likely that it will be necessary to carry out tests with regard to the protection of the persons who are constantly working these machines, as the number of daily exposures may be greatly in excess of those made annually in *x*-ray departments.

Summary

Miniature radiography may be regarded as an additional means of bringing under investigation symptomless persons who may subsequently be found to have chest abnormalities.

A comparison is made of a small number of miniature radiographs with the corresponding full-sized films.

Attention is drawn to the importance of developing miniature radiography at the present time. It is considered likely that after the war miniature radiography will play an important part in routine medical examination of the community.

Some of the difficulties that may be encountered are discussed.

I should like to thank Messrs. Stanley Cox and Co., Ltd., for the loan of their plant, and the medical committee of the Brompton Hospital for their permission to install it; also Dr. R. L. Rawlinson for his helpful co-operation.

TUBERCULOSIS IN RECRUITS

BY

SIDNEY H. GRAHAM, M.B., Ch.B., D.P.H., T.D.D.
Tuberculosis Officer

AND

MOSTYN DAVIES, F.S.S.
Medical Statistician

(From the Staff of the King Edward VII Welsh National Memorial Association)

The increase of tuberculosis among the civilian population of the countries of Europe and the high incidence of that disease in the Services during and after the last war have been well recognized. Tuberculosis in the Services cost the British Empire a very large sum of money in pensions and treatment allowances, but the amount of infection spread by tuberculous men passed as fit and by others with latent disease who developed active tuberculosis owing to the strain of military duties cannot be measured.

The Welsh National Memorial Association, which is responsible on behalf of the counties and county boroughs of Wales for the diagnosis and treatment of tuberculosis, offered early in the present war to examine and radiograph, free of charge, all men called up for military service in the counties of Anglesey and Carnarvon, which were chosen because they have a high incidence and a high death rate from the disease. The question was later taken up with the Ministry of Labour and National Service; but unfortunately, for various reasons, satisfactory arrangements could not be made in time to include the younger age groups—i.e., the under 30's—the important categories from the point of view of tuberculosis, and the project was therefore abandoned.

The committee, under the chairmanship of Lord Horder, which the Minister of Labour appointed to advise him on problems arising from the examination of recruits by civilian medical boards, reported that:

> "They had in particular explored the possibility of examining the chests of all recruits radiologically. The only way in which this could be done would, they said, be by miniature radiography, but although the adoption of this

method was the ideal to be aimed at serious practical difficulties arose . . . and it was considered impracticable at the present time."—(*Lancet*, 1940, 1, 28.)

The Tuberculosis Regulations, 1940, were, however, a result of the Horder Committee's recommendations. As applied to Wales, these regulations make it obligatory on medical officers of health of all sanitary authorities to give particulars in respect of notified male cases of tuberculosis of certain ages, and on tuberculosis officers to give particulars of all treatment in such cases, to the Ministry of Labour and National Service.

General Notes on the Investigation

The activities of the Welsh National Memorial Association cover a population of 2½ millions. A uniform system of case-taking and record-keeping is in use at all the clinics of that association. The numerous opportunities enjoyed by the medical staff for a frequent interchange of views through attendance at various institutions and at medical staff meetings have enabled a fairly uniform standard of diagnosis to be attained. As the available figures were fairly large and the data upon which they were based reasonably comparable, it was decided to investigate the incidence of tuberculosis in recruits referred by medical boards since the passing of the Military Training Act in May, 1939, up to December 31, 1940—paying particular attention to the reasons for reference. Careful histories were taken of all men referred; they were clinically examined; full-size (15 by 12 inch) radiographs were taken in each case, and the sputum was examined whenever available.

Numbers Investigated

The total number of cases referred by medical boards during the period under consideration amounted to 3,049, of which 1,180 had been previously examined by the tuberculosis officers and 1,869 were seen for the first time when referred by the medical board. These two groups have been kept separate, and Table I gives particulars of the "old cases" according to their condition at the time of reference to the tuberculosis officers by the medical boards.

TABLE I.—*Results of Investigation of Recruits previously known to the Tuberculosis Service*

Age Groups	Found to be Tuberculous							Observation	Non-tuberculous	Total
	Active			Quiescent	Arrested	Recovered	Total			
	Pulmonary		Non-pulmonary							
	T.B.+	T.B.−								
18-20	1	—	2	1	—	6	10	1	21	32
20-25	32	30	7	60	38	70	237	5	249	491
25-30	41	23	8	44	44	93	253	1	150	404
30-35	31	8	6	33	18	60	156	2	95	253
Totals	105	61	23	138	100	229	656	9	515	1,180

It will be seen that of the 1,180 old cases 656 had at some time previously been found to be suffering from tuberculosis; in 166 pulmonary cases the lesion was still active (105 of these had a positive sputum). There were 23 non-pulmonary active cases. Of these 656 old cases 238 (36.3%) were found, when referred by the medical boards, to have improved sufficiently to be classified as "quiescent" or "arrested," and a further 229 (34.9%) were regarded as recovered—a total of 467, or 71.2%. 515 of the 1,180 were old patients who had previously been found non-tuberculous but were referred by the medical boards to the tuberculosis officers in most cases because they said they had attended a tuberculosis clinic at some time or other.

Reason for Reference

A main object of the investigation was to learn why the medical boards had referred the 1,869 new cases to the tuberculosis officers. For this purpose they have been classified in Table II under four main headings—namely:

1. Contact History:
   (*a*) *Intimate.*—Household contact or prolonged contact to infection in the place of employment, etc.
   (*b*) *Casual.*—Contact with cases of tuberculosis of a more temporary nature.
2. Significant Past Personal History:
   Pleurisy, spontaneous pneumothorax, and haemoptysis.
3. Present History:
   (*a*) *Significant.*—Cough, especially of recent onset, sputum, haemoptysis of at least 1 drachm, pain in the chest, frequent colds, unwonted lassitude, progressive loss of weight, night sweats, etc.
   (*b*) *Non-significant.*—Bronchitis and asthma of long duration (considered non-significant in age group under consideration), and a variety of other symptoms.
4. Physical Signs:
   Abnormal signs in the chest and/or poor general condition, rapid pulse, etc.

TABLE II.—*Reason for Reference of Recruits not previously known to the Tuberculosis Service*

Reason	Age Group				Total
	18-20	20-25	25-30	30-35	
1. *Contact history:*					
(a) Intimate	20	176	130	172	498
(b) Casual	2	39	28	27	96
2. Significant past personal history	8	136	128	131	403
3. Present history:					
(a) Significant	8	129	89	76	302
(b) Non-significant	7	154	87	106	354
4. Physical signs	14	95	62	45	216
Totals	59	729	524	557	1,869

Of the total number of new cases, 498 (27%) were referred on account of intimate contact history; 96 (5%) on account of a casual contact history; 403 (21%) for their significant past personal history; 656 (35%) on their present history; and 216 (12%) because of physical signs.

Tables IIIa, IIIb, IIIc, and IIId show the results of examinations carried out by the tuberculosis officers under the four main categories of the reasons for reference.

Contact History

TABLE IIIa.—*Results of Investigation of Recruits Referred on Account of Contact History*

Age Groups	Tuberculous			Observation	Non-tuberculous	Total
	Pulmonary		Non-pulmonary			
	T.B. +	T.B. −				
18-20	—	—	—	—	22	22
20-25	1	9	—	2	203	215
25-30	1	11	—	3	143	158
30-35	3	8	—	4	184	199
Totals	5	28	—	9	552	594

No case of tuberculosis was found among the 96 men referred on account of a casual contact history. Of the 498 referred because of an intimate contact history, 33 (6.6%) were found to be suffering from pulmonary tuberculosis, and 9 others were considered to have signs and

symptoms suggestive enough of tuberculosis to warrant their being kept under further observation. In the 20-25 age group 10 cases out of a total of 215 referred (4.6%), in the 25-30 group 12 out of 158 (7.6%), and in the 30-35 group 11 out of 199 (5.5%) were found to be tuberculous.

Significant Past Personal History

TABLE IIIb.—*Results of Investigation of Recruits Referred on Account of Significant Past Personal History*

Age Groups	Tuberculous			Observation	Non-tuberculous	Total
	Pulmonary		Non-pulmonary			
	T.B. +	T.B. −				
18-20	—	—	—	—	8	8
20-25	2	5	—	2	127	136
25-30	3	5	1	4	115	128
30-35	1	5	—	2	123	131
Totals	6	15	1	8	373	403

Table IIIb shows the results of the examination of those men referred on account of a significant past personal history: out of a total of 403, 22 (5.4%) were found to be tuberculous and 8 others required further observation. In the 20-25 age groups 7 out of 136 (5.1%), in the 25-30 group 9 out of 128 (7.2%), and in the 30-35 group 6 out of 131 (4.6%) were tuberculous.

Present History

TABLE IIIc.—*Results of Investigation of Recruits Referred on Account of Present History*

Age Groups	Tuberculous			Observation	Non-tuberculous	Total
	Pulmonary		Non-pulmonary			
	T.B. +	T.B. −				
18-20	1	3	—	—	11	15
20-25	6	8	—	4	265	283
25-30	2	12	—	2	160	176
30-35	5	—	—	1	168	182
Totals	14	31	—	7	604	656

Table IIIc gives the results of the examination of recruits referred on account of "present history." Out of 656 men 45 (6.8%) were found to be suffering from pulmonary tuberculosis and 7 required further observation. In the 18-20 age group 15 cases only were referred, and of these 4 were tuberculous. The figures in this group are, of course, too small to be significant. In the 20-25 group 14 out of 283 (4.9%), in the 25-30 group 14 out of 176 (7.9%), and in the 30-35 group 13 out of 182 (7.1%) were tuberculous.

Physical Signs

TABLE IIId.—*Results of Investigation of Recruits Referred on Account of Physical Signs*

Age Groups	Tuberculous			Observation	Non-tuberculous	Total
	Pulmonary		Non-pulmonary			
	T.B. +	T.B. −				
18-20	—	1	—	—	13	14
20-25	—	1	3	—	91	95
25-30	3	1	—	3	55	62
30-35	1	2	—	3	39	45
Totals	5	5	3	6	198	216

Table IIId shows the results of the investigation of those recruits referred on account of physical signs. Out of 216 examined, 12 (5.5%) were found tuberculous, and 6 were kept under observation. The figures in the 18-20 group are again too small to be of any significance. In the 20-25 group 4 cases out of 95 (4.2%), in the 25-30 group 4 out of 62 (6.4%), and in the 30-35 group 3 out of 45 (6.7%) were tuberculous.

TABLE IV.—*Total Recruits Referred who were not previously known to the Tuberculosis Service, and who were found to be suffering from Tuberculosis*

Age Groups	Tuberculous			Total	Observation
	Pulmonary		Non-pulmonary		
	T.B. +	T.B. −			
18-20	1	4	—	5	—
20-25	9	23	3	35	8
25-30	9	29	1	39	12
30-35	10	23	—	33	10
Totals	29	79	4	112	30

Table IV summarizes in age groups the recruits not previously seen by the Association (of which the totals are given in Table II), found to be either suffering from tuberculosis or sufficiently under suspicion to need further observation. Only 59 men aged 18 to 20 were referred by the medical boards, and these were volunteers. Five of them were found to have pulmonary tuberculosis. In the 20-25 group 729 men were referred: 32 had pulmonary tuberculosis and 3 non-pulmonary tuberculosis—a total of 35 (4.8%). Out of 524 in the 25-30 group 38 had pulmonary tuberculosis and 1 non-pulmonary tuberculosis—a total of 39 (7.4%). In the 30-35 group 33 out of a total of 557 referred had pulmonary tuberculosis—a percentage of 5.9.

To sum up, 112 cases of tuberculosis were found among 1,869 recruits referred who were not previously known to the Tuberculosis Service—a percentage of 6; and 30 other cases were kept under observation.

In order to furnish some idea of the average number of cases found tuberculous among male patients referred to the Association through the usual channels in the course of a year in the same age groups, the figures for 1940 are given in Table V.

TABLE V.—*Male Cases aged 18 to 35, other than Recruits, Referred to Tuberculosis Officers during 1940*

Age Groups	Tuberculous				Observation	Non-tuberculous	Total
	Pulmonary		Non-pulmonary	Total			
	T.B. +	T.B. −					
18-20	39	46	17	102	24	264	390
20-25	102	102	25	229	41	583	853
25-30	67	59	22	148	22	536	706
30-35	83	75	13	171	23	583	777
Totals	291	282	77	650	110	1,966	2,726

It will be seen that out of a total of 2,726 cases 650 (23.8%) were tuberculous, and a further 110 were under observation. It should be borne in mind, of course, that all these patients had suffered from such a degree of ill-health that they had found it necessary to consult a doctor, and had been referred by him to the Memorial Association on account of signs or symptoms suggestive of tuberculosis.

Discussion

It may be pointed out that the diagnosis of pulmonary tuberculosis was arrived at by our medical officers only after a careful correlation of symptoms, physical signs, sputum examination, and radiological findings. Following the teaching of the Trudeau Sanatorium, special significance was attached to certain symptoms and signs—namely:

1. History of pleurisy with effusion.
2. History of frank haemoptysis of more than 1 drachm.
3. Persistent rales at one apex.
4. Radiological evidence of infiltration of the lung parenchyma.

No recruit was regarded as suffering from tuberculosis unless there was radiological evidence of infiltration in the lung parenchyma for which no other cause could be found. If the evidence pointed to the presence of a healed lesion, this was not included in the diagnosed group. In all cases diagnosed as tuberculous the lesion was considered to be "active," and in most of them institutional treatment was indicated. We found that medical boards varied considerably in their conception of the indications for reference. For example, several of them referred practically every man giving a history of contact with tuberculosis, while others appeared to attach less importance to this factor.

As already stated, 3,049 recruits were referred to the Memorial Association, but 1,180 of them were cases previously known; 656 of the latter had at some time or other been found to be suffering from tuberculosis, 9 were still under observation, and 515 were old non-tuberculous cases. Undoubtedly many old cases in which the diagnosis of tuberculosis was obvious were not referred by the medical boards. This group is of little importance so far as the present investigation is concerned.

Of the 1,869 new cases referred, the numbers in the three quinquennial groups 20-25, 25-30, and 30-35 are 729, 524, and 557, respectively; the numbers found to be tuberculous in each group are practically the same—namely, 35, 39, and 33. It is not suggested that these figures give any indication of the incidence rate of tuberculosis in these groups, or that the cases referred are in any respect a typical cross-section of the population. This group of new cases is to some degree selective, but, on the other hand, the patients composing it do not fall into the same category as the normal new cases referred to the Memorial Association. The large majority had not found it necessary to consult their own doctor on account of ill-health. On the other hand, the medical boards, upon examination, discovered some reason for referring them to the tuberculosis officer. They therefore fall into an intermediate group.

We wish to stress the point that the figures summarized below are not incidence rates of tuberculosis in the relevant age groups, but are percentages of cases found tuberculous among men referred to the Tuberculosis Service.

Summary of Percentages of Cases found Tuberculous

Age Groups	Contact History	Significant Past Personal History	Present History	Physical Signs	Total
20–25	4.6	5.1	4.9	4.2	4.8
25–30	7.6	7.2	7.9	6.4	7.4
30–35	5.5	4.6	7.1	6.7	5.9
Totals	5.6	5.4	6.8	5.5	6.0

There is only a slight variation in the percentage of cases found tuberculous under the main reference categories. The highest proportion of cases suffering from tuberculosis was found among those referred on account of "present history." This might have been expected in view of the fact that these men actually complained of indifferent health at the time of examination by the medical boards, and the symptoms were sufficiently suggestive of tuberculosis to warrant their being referred to the tuberculosis officers.

The percentage of those found tuberculous referred on account of contact history fully justifies the importance of contact examination, at any rate of young adult males, especially as most of these cases had a multiple family history.

The medical boards appear quite rightly to have attached importance to a previous history of haemoptysis or pleurisy. We appreciate that, as stated by Gregory Kayne (1940), "little reliance can be placed on a man's statement that he has suffered from pleurisy unless he has been admitted to hospital"; but out of a total of 499 cases among the 3,049 referred who stated they had had a previous pleurisy 116 (23%) subsequently developed active pulmonary tuberculosis. Out of 156 who stated that they had had a frank haemoptysis of at least 1 drachm, 45 (28%) were found to have tuberculosis.

Most of those referred on account of physical signs made no complaint at all of ill-health, and the percentage of 5.5 found tuberculous proves that a physical examination of the patient may provide the first evidence of the existence of diagnosable disease.

Our results show that the standards adopted by medical boards for deciding upon the reference of cases to tuberculosis officers should not be too rigid.

In the following table the percentage found tuberculous among the "new" recruits referred is compared with the percentages of "ordinary" male new cases found tuberculous in the same age groups.

Age Groups	Recruits	New Cases Examined in 1940
20–25	4.8	26.3
25–30	7.4	20.9
30–35	5.9	22.0
Totals	6.0	23.8

The highest percentage of recruits found to be suffering from tuberculosis falls in the 25-30 age group, and the highest for the new cases in the 20-25 group. Of male new cases aged 18 to 35 examined by the Memorial Association during the year 1940 24% were tuberculous. This is four times the number observed among the new recruits; but, nevertheless, this figure of 6% for recruits is high, having regard to the fact that these men did not suffer from such a degree of ill-health as to make it necessary for them to consult their own doctors.

According to Dr. Robert E. Plunkett (1941), General Superintendent of Tuberculosis Hospitals of the New York State Department of Health, "19, or 1.4%, of the 1,401 men called under the Selective Service Act and given physical examination and chest *x*-ray during the week of November 25, 1940, were found to have tuberculosis." This group of 1,401 is not comparable to our group of recruits, as it was not in any way selected, all recruits in New York State being subjected to a radiological examination. It is, however, rather more comparable than the "ordinary male new cases" referred to the Memorial Association's staff in the course of work through the usual channels. Our figure of 6% found tuberculous is more than four times that given by Dr. Plunkett.

Several countries, including the Dominion of Canada and the Commonwealth of Australia, have adopted a scheme whereby all recruits are subjected to radiological examina-

tion, and we are of opinion that our figures are significant enough to justify the adoption of a similar scheme in this country.

Conclusions

Of 1,869 recruits referred to the Welsh National Memorial Association's tuberculosis officers by the medical boards and then seen for the first time, 112 (6%) were found to be suffering from active tuberculosis, as compared with 23.8% of male new cases in the same age group examined in 1940 in the ordinary course of work, and with 1.4% of the men called up and examined as a routine measure, and not because they were referred by medical boards, by Dr. Robert E. Plunkett.

Of the 112 recruits found tuberculous, 108 (or 5.7% of all those referred) had pulmonary tuberculosis, and 4 (0.3%) non-pulmonary tuberculosis.

An additional 30 cases (1.6%) required further observation.

The percentage figures of cases found tuberculous analysed under the four main headings set out in Table II show that the indications for the reference of cases by medical boards to tuberculosis officers should be comprehensive, and even then cases of active or latent tuberculosis may be missed. It is better that the total cases referred should be large, and the percentage found tuberculous low, than that only a few cases should be referred, with a high percentage found tuberculous.

The finding of a substantial number of tuberculous recruits in Wales strongly supports the view held by most tuberculosis workers that all recruits should be subjected to a radiological examination. It is regrettable that the Horder Committee has advised that this "was impracticable at the present time." The difficulties are appreciated, but with the modern developments of miniature radiological technique (Cranch, 1940) we feel it would have been a task not impossible of accomplishment, and at a reasonable cost.

It is unfortunate that the Public Health (Tuberculosis) Regulations, 1940, were not in force when the first age groups were called up, as these regulations apply only to men aged 33 and upwards and the "new 20's."

The percentage of cases (6.6) found tuberculous who were referred by medical boards to tuberculosis officers solely on account of an intimate contact history emphasizes the importance of the contact examination of young adults, and it would be well if all recruits with a family history of tuberculosis were referred to the Tuberculosis Service by the medical boards.

Our thanks are due to Prof. Picken, Mansel Talbot Professor of Preventive Medicine, University of Wales, for his very valuable advice and assistance. The tuberculosis officers of the Welsh National Memorial Association readily put all their records at our disposal and gave every help. To Dr. D. A. Powell, principal medical officer of the Memorial Association, we are particularly indebted for making this investigation possible and for his guidance throughout.

ADDENDUM

Since writing the above, an exhaustive report on pulmonary tuberculosis in recruits has been published by Major Douglas Galbraith (1941), Deputy Assistant Director-General of Medical Services, Australian Army Medical Corps, together with the report on the bacteriological examinations by Reginald Webster (1941), Honorary Major, Australian Army Medical Corps Reserve.

More than 100,000 recruits of the Australian Imperial Forces have been subjected to routine chest *x*-ray examination by the method of miniature radiography, and of that number 0.56% presented radiological evidence of active pulmonary tuberculosis; 1.04% gave radiological evidence of active or latent tuberculosis of the reinfection type; and 0.25% and 0.12% showed radiological evidence of non-tuberculous pulmonary pathology and of cardiac or vascular lesions, respectively.

The importance of radiological examination of all recruits is stressed by Major Galbraith, who gives three main reasons as follows:

> "Disregarding the humanitarian aspect and examining the problem strictly from the Army standpoint, the most important factors which operate when a soldier develops active tuberculosis are: (1) the loss of his services and of the work hours spent in giving him his military training; (2) the danger of his infecting others in the close proximity entailed in hutments and tents; (3) the financial loss to the taxpayer represented by the cost of treatment and by pension."

His figures are, of course, not comparable with our figures any more than are those of Dr. Plunkett.

TRICHLORETHYLENE AS AN INHALATION ANAESTHETIC

BY

C. LANGTON HEWER, M.B., B.S., D.A.

Senior Anaesthetist to St. Bartholomew's Hospital, Hill End Hospital, St. Albans, and St. Andrew's Hospital, Dollis Hill; Anaesthetist to the Brompton Chest Hospital

WITH A PREFATORY NOTE

BY

CHARLES F. HADFIELD, M.B.E., M.D., D.A.

Consulting Anaesthetist to St. Bartholomew's Hospital; Anaesthetist to the Emergency Medical Service; Honorary Secretary of the Joint Anaesthetics Committee of the Medical Research Council and the Royal Society of Medicine

Prefatory Note

Some months ago, in my capacity as honorary secretary of the Anaesthetics Committee, I received a letter from Mr. C. Chalmers of Muswell Hill asking for information about the anaesthetic properties of trichlorethylene. I had at the time no information on the subject, but, from the references that I could find (and these were very few, as I was working at a distance from all medical libraries) and from the very pregnant facts supplied by Mr. Chalmers himself, it seemed obvious that the anaesthetic properties of this drug merited an investigation by my committee. After some correspondence with my friend, and colleague on the committee, Mr. C. Langton Hewer, I was glad to know that he was in entire agreement with me and, further, was himself willing, even anxious, to undertake the investigation. Needless to say, it could not have been placed in more competent hands, and this paper, although only an interim report, certainly suggests that the research was completely justified.

My purpose in writing this prefatory note is not only to record the facts stated above but also to secure adequate recognition of the unusual part taken by my correspondent. Mr. Chalmers is not himself a medical man, though he appears to be a proficient chemist and to possess an uncommon knowledge of medical matters. At the time the investigation began we were all unaware that trichlorethylene was obtainable in this country in a form pure enough for inhalation, and in consequence Mr. Chalmers himself prepared and provided at his own cost the supplies of the drug that were first employed. It was only some time later, when this supply had been used up, and Mr. Chalmers, owing to war conditions, found himself unable

to prepare any more, that he suggested application to Imperial Chemical Industries. We then found that this firm was already manufacturing, under the trade name of "trilene," a purified form of the substance specially prepared for medical purposes, though with no reference to inhalation or general anaesthesia. Trilene is, in fact nothing but specially purified trichlorethylene to which a small proportion of a stabilizing agent has been added.

Even before communicating with me Mr. Chalmers had made experiments to test the anaesthetic qualities of trichlorethylene. He explained to me that, not being a medical man, the only subject upon whom he could experiment was himself. Accordingly, using very makeshift apparatus, he actually anaesthetized himself and carefully noted, so far as was possible, his sensations and the resulting after-effects. In general his report tallied very closely, so far as it went, with Mr. Hewer's later findings, but he specially stressed the absence of nausea and vomiting. He did, however, mention one sequel which is not referred to in the present paper. It may have been accidental, but it is worth recording as a subject for further observation. He noticed, about one day following administration, a slight distension of the intestines accompanied by some pain in the region of the descending colon. This he thought might be due to a decomposition of the inhaled anaesthetic, possibly into carbonyl chloride.

More could be written about the active part taken by Mr. Chalmers in instituting and assisting this investigation, but it seems unnecessary to stress further the credit due to him.

For the information of any who may be interested in the properties of this almost new and apparently useful anaesthetic agent it may be added that although trilene is manufactured by Imperial Chemical Industries it is actually marketed for them by Messrs. Macarthys, Ltd., wholesale chemists, Market Place, Romford, Essex, from whom no doubt adequate supplies are obtainable.

C. F. H.

Physical Properties and Uses of Trichlorethylene

Trichlorethylene has the chemical formula $CCl_2:CHCl$ and is a colourless heavy liquid with a fruity smell which somewhat resembles, but is quite distinguishable from, that of chloroform. The specific gravity of the liquid is 1.47 at 15° C., and its boiling-point is the high one of 87° C. It is not inflammable under any circumstances, nor will its vapour explode when mixed in any proportion with air, oxygen, or nitrous oxide. Pure trichlorethylene tends to decompose in strong sunlight and should therefore be stored in amber-coloured bottles. The addition of 0.01% thymol greatly retards decomposition. The drug has high solvent power for fats, but is practically insoluble in water. It was first described in 1864.

Commercial Uses.—Trichlorethylene is chiefly used for the dry-cleaning of clothes, the de-greasing of metals, and the de-waxing of lubricating oils. For these purposes the fluid is sold under a variety of trade names, such as trethylene, gemalgene, chlorylene, and triklone. These preparations are not pure enough to be used for inhalation.

External Application.—A few years ago the use of trichlorethylene was recommended as a skin cleanser and to clean up dirty wounds and burns (Trumper and others, 1936). For these purposes Imperial Chemical Industries, Ltd., produced a specially purified liquid known under the name "trilene." This product has been generously supplied by the company for inhalation purposes in the work about to be described.

Therapeutic Inhalation.—The drug has been in use for some years for the relief of pain in trigeminal neuralgia. For this purpose the vapour is inhaled from broken capsules as in the case of amyl nitrite. The origin of this procedure is curious. It was reported by two separate observers that patients suffering from chronic trichlorethylene poisoning showed complete bilateral paralysis of all divisions of the trigeminal nerve (Plessner, 1916; Gerbis, 1928). It was supposed that the drug had some specific action on this nerve, and its administration for trigeminal neuralgia was suggested (Oljenick, 1928) and shown to be effective (Glaser, 1931). It appears to me that it is much more probable that the pain is relieved because a state of general analgesia is induced. This condition has been demonstrated several times before consciousness was lost.

Industrial Poisoning.—Several European writers have recorded cases of poisoning in workers in factories when trichlorethylene was employed. Various symptoms have been described, including giddiness, vomiting, optic neuritis, and various palsies (Plessner, 1916; Gerbis, 1928). Some cases have proved fatal (Stüber, 1931). So far as can be ascertained, all the affected patients had been exposed to the vapour of commercial trichlorethylene, which may contain a great variety of impurities.

Animal Experiments

In 1921 Joachimoglu found that pure trichlorethylene vapour was not irritating to the respiratory tract, did not haemolyse the blood, and did not cause fatty degeneration of the liver. In 1934 Herzberg reported that the liver, spleen, kidney, diaphragm, pancreas, heart muscle, lung, adrenal, and pectoral muscle taken from three dogs killed by overdosage of trichlorethylene after having been deeply anaesthetized for periods of two and a half to three and a half hours showed no gross or microscopical pathological changes. In 1935 Krantz and others anaesthetized the same rats repeatedly (up to thirty times) with trichlorethylene. The animals were then killed and the various organs examined. Although some pathological changes were found they were in the main slight and inconclusive. In rabbits slight hyperglycaemia was noted. The same workers found that anaesthesia could not be obtained by rectal administration of the drug and that nerve conduction was not affected by local application of trichlorethylene. In 1939 Lande and others anaesthetized rabbits, guinea-pigs, rats, and mice with trichlorethylene daily for two and a half months, the duration being from fifteen minutes to one and a quarter hours a day. After being killed some inflammatory changes in the liver and kidneys were noted.

It may reasonably be concluded from these extremely severe tests that in animals trichlorethylene is only slightly toxic—certainly much less so than chloroform.

Previous Work in Human Anaesthesia

The only published work which can be traced is that on a series of 300 patients anaesthetized with trichlorethylene by Striker and others in America in 1935. These were all short administrations for minor operations, and in some cases analgesia only was produced. Eight patients became violent in the second stage, and the third stage of anaesthesia could not be reached. One patient stopped breathing from an overdose but recovered under artificial respiration. After-effects were slight, and on the whole the drug was regarded as a satisfactory anaesthetic.

In the following year (1936) the Council of Pharmacy and Chemistry of the American Medical Association considered the evidence for usefulness of trichlorethylene and concluded that "the case had not been completely made out."

After careful consideration of the data summarized above it was thought justifiable to pursue the investigation of trichlorethylene as an anaesthetic in the human subject.

Details of Present Investigation

The number of administrations was 127 and, although this is admittedly a small series, an effort was made to choose representative cases. Most of the commoner major operations were performed under trichlorethylene anaesthesia, their duration varying from seven minutes to three hours ten minutes, the average being about forty-five minutes. The patients were either (a) air-raid casualties, (b) soldiers—most of whom were wounded evacuated from Dunkirk—and (c) ordinary hospital civilian patients. Their ages varied from 14 months to 81 years.

Methods of Administration and Cost

It soon became evident that an open-mask administration was not practicable owing to the low volatility of trichlorethylene. In America a special apparatus has been devised to vaporize the drug, incorporating an air compressor driven by an electromotor (Jackson, 1934). It was felt, however, that if the anaesthetic was to be of any use under Service or oversea conditions, standard apparatus should be employed. In most administrations, therefore, trichlorethylene was put in the chloroform bottle of a continuous-flow apparatus and used as an adjuvant to nitrous-oxide - oxygen. When used with partial rebreathing this method was quite satisfactory. In most cases a face-piece was employed, but, when indicated, a nasal or oral endotracheal tube was passed.

With the CO_2-absorption technique it is essential to have the vaporizer in the patient's respiratory circuit. Insufficient concentration of trichlorethylene is obtained if the basal oxygen feed only is used to vaporize the drug as in the single-phase Waters system or in the two-phase apparatus supplied as standard to the E.M.S.

If the drug had been purchased at hospital price it was calculated that the cost per case would have averaged about 4½d.

Stages and Signs of Anaesthesia

In most respects trichlorethylene resembles chloroform rather than ether, and the signs of the various stages of anaesthesia are similar to those encountered with nitrous-oxide - oxygen with chloroform as an adjuvant. Some degree of general analgesia appears to be present in the first stage, and this was proved to be due to trichlorethylene and not to the nitrous oxide by occurring when pure oxygen was used to vaporize the drug. The second stage was not usually marked, but in one or two patients violent excitement did occur. This can, of course, be avoided by starting with an intravenous barbiturate, but it was not done lest it should confuse the issue. The third stage was characterized by quiet automatic breathing and a variable degree of muscular relaxation. This was sufficient for the operative procedures except in three patients. The first was a muscular young man who was having a partial gastrectomy for ulcer; the second was a patient from whom a large malignant ovarian cyst was removed; and the third was a soldier who underwent manipulation of the spine. In each instance the addition of diethyl ether vapour for a short time secured the necessary relaxation.

One opportunity occurred for observing the effect of trichlorethylene upon the uterine musculature. An abdominal hysterotomy was performed to terminate pregnancy because of active phthisis. The surgeon remarked upon the exceptionally good retraction of the uterus following extraction of the foetus.

After an average of twenty minutes' administration it was found that the vapour concentration of trichlorethylene could be greatly reduced without prejudice to muscular relaxation. On one occasion an overdose was inadvertently given. Respiratory arrest occurred, but no difficulty was encountered in restoring natural breathing. The pulse remained steady throughout.

Effects on Respiratory System

The odour of trichlorethylene is not pungent, nor does its vapour appear to have any irritant effect upon the respiratory passages. It follows that the vapour concentration can be increased quickly, leading to the rapid induction of anaesthesia. No excessive salivation or secretion of mucus was noticed even if premedication had been inadequate or badly timed. Nineteen major thoracic operations were included in the series, as were six abdominal sections on patients suffering from severe chronic bronchitis or active phthisis. In no case was there any noticeable exacerbation of the pulmonary disease.

The depth of respiration was not appreciably altered, but in about 30% of patients some increase in the rate occurred. This usually subsided after fifteen to twenty minutes, but in a few cases it persisted. The respiratory rate was particularly high in some patients during operations involving an open pleura, and this constituted a definite disadvantage in thoracic surgery.

Effects on Cardiovascular System

The blood pressures remained within normal limits except for some rise if the second stage of anaesthesia was marked by much excitement. No case of pronounced shock occurred in the series. The pulse rate was usually slightly higher than normal, as is the case with most inhalation anaesthetics.

Particular attention was paid to the heart rhythm, as trichlorethylene contains three chlorine atoms in its molecule, and at least two other compounds with this characteristic can cause grave cardiac irregularities and even primary cardiac failure. (These drugs are chloroform and trichlorethanol.) (Wood, 1938; Hewer and Belfrage, 1938.) No cardiac irregularities could be detected clinically except sinus arrhythmia in a few young patients, which disappeared when full anaesthesia was reached. Several patients with extrasystoles before operation showed a regular rhythm after anaesthesia had been induced with trichlorethylene. This is, of course, common with most inhalation anaesthetics.

Dr. K. D. Keele kindly took electrocardiograms with the Cossor-Robertson cardiograph during the induction of anaesthesia in 15 cases. Continuous visual direct observation was made in all the cases included. This was started previous to the induction of anaesthesia, when a short photographic record of Lead II was taken; direct observation was then continued until the patient was well into the third stage of anaesthesia, when a second record was made. Of the 15 cases so observed, in 14 there was no alteration in the tracing, apart from a slight decrease in the sinus tachycardia as the third stage of anaesthesia was reached. In one instance regular auricular extrasystoles alternating with normal systoles occurred over a period of some three minutes and then ceased. In two other cases occasional ventricular extrasystoles were seen during the second stage. These disappeared as the third stage was reached. In no case were multiple ventricular extrasystoles seen. These were particularly looked for in view of their comparatively frequent occurrence during chloroform anaesthesia. This limited number of observations thus suggests that there is no evidence of any particular cardiac danger from trichlorethylene.

It seems only fair to mention a fatality which occurred after the conclusion of this series, following the administration of trichlorethylene by a colleague.

The patient was a woman, aged 33, who was to have an empyema drained. Anaesthesia was induced uneventfully with nitrous-oxide - oxygen and trichlorethylene. After a rib resection a large exploring needle was passed in several directions to locate the pus, but without result. At this point temporary apnoea occurred, but natural breathing was soon re-established, and the remainder of the operation was completed under pure nitrous-oxide - oxygen. Just as the wound was being closed the respiration and circulation ceased, apparently simultaneously, and all efforts at resuscitation failed.

The relevant findings at the necropsy were: (1) a localized empyema higher than the exploring needle had reached; (2) free blood in the pleural and peritoneal cavities; and (3) degeneration of the heart muscle. Some air was present in the cerebral arteries, but the diagnosis of air embolism could not be definitely established as the vessels were unfortunately not ligated before the brain was lifted out of the skull.

It is my opinion that trichlorethylene was not responsible for this patient's death, and I have knowledge of an almost exactly parallel case in which local analgesia only was employed. It might be noticed that, since no trichlorethylene had been used for five minutes before circulatory failure occurred, the concentration of the drug in the air passages (with a partial rebreathing circuit) must have been negligible.

Effects on Sugar Metabolism

Dr. A. Jordan kindly made some blood-sugar estimations before, during, and after anaesthesia with trichlorethylene. In no case was there much disturbance, and on taking an average it could be said that there was no significant change. This contrasts with the rise which constantly occurs with chloroform and ether (Hewer, 1939).

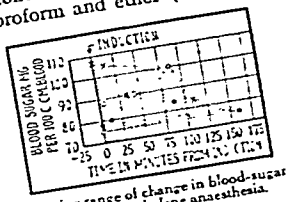

Chart showing range of change in blood-sugar level during trichlorethylene anaesthesia.

One diabetic patient was included in the series. An abdominal operation lasting 1 hour 15 minutes was performed under nitrous-oxide - oxygen - trichlorethylene. The sugar tolerance was tested one week after operation, and was found to be unchanged.

Effects on Blood Urea

Blood-urea estimations were made by Dr. Jordan upon 5 patients before, during, and after anaesthesia. The changes were so slight as to be within the range of experimental error. Here again the contrast with ether and chloroform is marked.

After-effects

Of the series of patients 61% had no nausea or vomiting, 26% had nausea or slight vomiting, and 13% had severe vomiting; 5% complained of headache. Those who had had experience of diethyl ether commented favourably on the absence of an unpleasant taste or smell.

In most cases the urine was tested as a routine on the day after operation. In one instance only was the presence of albumin found but acetone was always absent. This is in marked contrast with other anaesthetics. For example, albuminuria has been found almost constantly after the prolonged administration of ether and in about 20% of patients anaesthetized with chloroform (Stephen, 1929). Acetonuria has been demonstrated in 67% of patients operated upon under all forms of general anaesthesia and in 85% under local analgesia (Schulze, 1924).

No pulmonary complications were observed, and, as already mentioned, existing lesions did not appear to be affected.

Summary and Conclusions

This article must be regarded as an interim report, and it is not suggested that our present knowledge of trichlorethylene warrants its recommendation as an inhalation anaesthetic. At the same time the drug appears to have enough good qualities to render a more exhaustive investigation profitable.

It appears that trichlorethylene generally resembles chloroform but is less potent and less toxic.

It is desired to express thanks for much help from Mr. B. Rait-Smith, who made nineteen administrations; also to Dr. Keele for his electrocardiographic work and to Dr. Jordan for his biochemical investigations.

USE OF SULPHAPYRIDINE IN SUBACUTE BACTERIAL ENDOCARDITIS

WITH REPORT OF A CASE

BY

J. G. MACLEOD, M.B., Ch.B., M.R.C.P.Ed.

Late Resident Medical Officer, Emergency Medical Service

In the treatment of subacute bacterial endocarditis attention has recently been focused on the use of sulphapyridine combined with heparin. The rationale of this treatment is that the latter drug is thought to prevent the deposition of further thrombus on the affected valves. As a result the bacteria are exposed to the sterilizing action of the sulphapyridine, and the check in the growth of the vegetation gives the processes of repair an opportunity to gain the ascendancy. The results of published cases treated along these lines are noted in Table I.

TABLE I.—*Cases treated with Sulphapyridine and Heparin*

No.	Author	Result
1	Kelson and White (1939)	Death from pulmonary infarct 2 weeks after treatment stopped
2	"	Bedridden with congestive heart failure, but "no evidence of bacterial endocarditis" 19 weeks after treatment stopped
3	"	Symptom-free and negative blood cultures 18 weeks after treatment stopped. Returned to work
4	"	Death during treatment from subdural haemorrhages following emboli
5	"	Death during treatment following a reaction due to faulty heparin
6	"	Little change
7	"	Free from evidence of disease 4 weeks after treatment stopped
8	Friedman, Hamburger, and Katz (1939)	Death during treatment from cerebral haemorrhage. No sulphapyridine used in this case
9	Dockeray and Kawerau (1940)	Death 3 months after treatment stopped
10	Witts (1940)	Death during treatment from subarachnoid haemorrhage
11	Fletcher (1940)	" " " "
12	Petch (1940)	Remained well for 6 months
13	"	Death from intracranial haemorrhage
14	"	" " toxic jaundice
15	"	" " " "

These results are not encouraging. Death from haemorrhage, particularly cerebral haemorrhage, is a very real danger.

Maegraith and Vollum (1938) claim that sulphapyridine is the drug with the most definite inhibitory action on the

growth of *Streptococcus viridans*. On the other hand, Swain (1940) suggests that some strains of *Strep. viridans* may be resistant to sulphapyridine. Sulphapyridine, however, is probably the drug of choice if a chemotherapeutic agent is to be used. It would also be the drug of choice in those rarer cases due to *B. coli*, pneumococci, or haemolytic streptococci. A number of cases have been treated with this drug alone in various doses. The results of published cases are given in Table II.

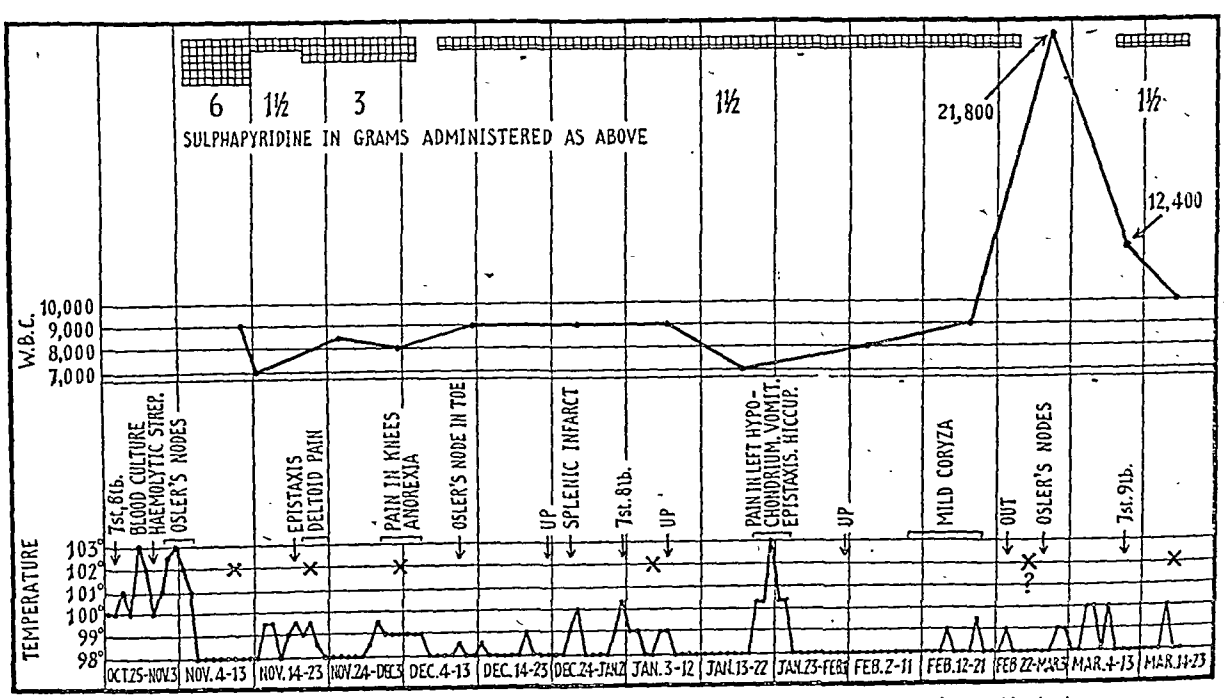
TABLE II.—*Cases treated with Sulphapyridine*

No.	Author	Result
1	Whitby (1938)	Life undoubtedly prolonged. Clinical improvement in general health and comfort. Anaemia and fever lessened
2	"	
3	Ellis (1938)	Symptomatic improvement, but death 3 weeks after stopping treatment
4	"	Symptomatic improvement. Patient discharged
5	Andrews (1940)	Improvement, but death 2 weeks after starting treatment
6	"	Apparent cure
7	Richards (1940)	Recovery claimed
8	Ravina (1939)	Decided improvement

These results, admittedly in a very small series of cases, are encouraging. Two cases of cure are claimed. In others the authors are emphatic that a decided improvement in the general condition of the patient occurred and that life was undoubtedly prolonged. This is a striking advance. It is possible, also, that those cases treated with sulphapyridine and heparin, and showing an improvement, would have benefited equally with sulphapyridine alone. It would appear, as was pointed out by Donovan (1940), that in the treatment of subacute bacterial endocarditis there seems to be more hope in further chemotherapeutic development than in heparin as an adjunct.

The difficulty to be overcome is the mechanical one of attacking the bacteria embedded in the vegetations. If, however, an adequate concentration of sulphapyridine were maintained in the blood stream over a long period, then, in the event of bacteria becoming exposed—e.g., by the separation of a portion of thrombus—they would be liable immediately to be attacked by the chemotherapeutic agent already present. In the majority of the cases quoted above (Table II) treated with encouraging results with sulphapyridine alone, embolic phenomena were frequent.

That sulphapyridine may be given continuously over long periods is suggested by the work of Coburn and Moore (1940). These authors administered 3 grammes of sulphanilamide daily continuously for periods of several months as a prophylactic measure in rheumatic children. No major toxic effects were noted. It is suggested, therefore, that in cases of subacute bacterial endocarditis treated with sulphapyridine an initial full course be given to sterilize the blood stream, followed by a smaller dose given continuously over a long period to maintain this sterilization and to attack the bacteria in the vegetation as the opportunity arises. A case treated along these lines is described.



Report of Case

The patient, a man aged 20, had had rheumatic fever when 9 years old and again when 13. On each occasion he had spent three months in bed, followed by two months' convalescence. His heart was said to be affected at the second attack. In September, 1940, he complained of tiredness, breathlessness on exertion, and, later, of poor appetite, nausea, constipation, and pains in the fingers. He was admitted to hospital on October 25.

On examination a pale, tired-looking young man was seen lying listlessly in bed. He was undersized, poorly developed, and poorly covered; height 5 ft. 5 in., weight 7 st. 8 lb. He had typical café-au-lait complexion and hot moist skin. There was slight clubbing of fingers; and two or three Osler's nodes appeared daily, at the outset, in the pulp of fingers and toes. Neither jaundice nor pitting oedema was present. The temperature was 100°, the pulse 100, and the respirations 20.

There was visible precordial pulsation in the fifth intercostal space lateral to the nipple line, and a systolic thrill could be felt in this area. The apex beat was forceful, 9 cm. from the midline; the mid-clavicular line was 8.5 cm. from the midline. Apical systolic and basal systolic and diastolic murmurs were present. These murmurs and the quality of the heart sounds varied considerably in character from day to day. A radiograph on March 10, 1941, revealed mitral heart—measurements: transverse diameter 14 cm., longitudinal diameter 17 cm. The spleen was not palpable, but dullness over the splenic area extended to the costal margin. The urine contained albumin and red blood cells.

The patient was kept strictly at rest in bed and was nursed as much as possible near an open window. He was given iron, yeast, and cod-liver oil and malt. On October 31 a blood culture yielded a profuse growth of haemolytic strepto-

The daily temperature noted above represents the highest reading recorded on a four-hourly chart. × = Negative blood culture.

occi. His general condition remained extremely poor until sulphapyridine was started on November 5, 1 gramme being given four-hourly. A very decided improvement was evident in the course of a few days. The sulphapyridine was reduced on the 14th to 0.5 gramme thrice daily, but was increased on the 21st to 0.5 gramme four-hourly because of a return of fever. It was stopped on December 6, as persistent anorexia developed, but was restarted in doses of 0.5 gramme thrice daily on December 9 and was maintained continuously at this level until February 25, 1941.

During this time the improvement in the patient's condition continued, although it was interrupted temporarily on several occasions by minor upsets (see Chart). Four successive blood cultures were negative. The fifth unfortunately was contaminated, but the sixth was again negative. There was a striking decrease in the frequency of Osler's nodes while sulphapyridine was being given. A blood count on December 3 showed red cells, 4,400,000 per c.mm.; haemoglobin, 70%; colour index, 0.8; white cells, 8,600 per c.mm.—polymorphs, 74%; eosinophils, 1%; lymphocytes, 24%; monocytes, 1%. On March 1 the readings were: red cells, 4,530,000 per c.mm.; haemoglobin, 85%; colour index, 0.9; white cells, 21,800. Leucocyte counts, made at frequent intervals throughout, varied between 7,000 and 22,000 per c.mm. (see Chart). The blood concentration of sulphapyridine while 0.5 gramme was being given thrice daily was: free 1.2 mg., acetylated 1.3 mg. per 100 c.cm. The sulphapyridine was discontinued on February 25 in view of the very decided improvement. As fever returned it was restarted on March 10 and was continued until discharge.

By the date of discharge the patient was up for the greater part of the day, and was out for several hours in the afternoon. He insisted on being discharged because he felt so well.

Comments

The outstanding result of the treatment was the change in the patient's condition. From a miserable tired young man bathed in sweat he became cheerful and active and had long periods free from fever. An advanced case of subacute bacterial endocarditis was arrested and very decidedly improved. As occurred in Whitby's (1938) cases the anaemia also improved. Another interesting result was the striking diminution in the number of Osler's nodes while sulphapyridine was being given

A total of 241.5 grammes of sulphapyridine was administered. Apart from transient nausea and anorexia, no toxic effects were noted. Whitby (1938) states that resistance to the drug may develop. That this did not occur in the case reported here is suggested by the fact that when the drug was discontinued after 226.5 grammes had been given the fever that followed was readily controlled by further small doses.

The case is unusual in that the streptococcus isolated was of the haemolytic type, and the encouraging results obtained may have been due in part to the fact that this organism is more readily destroyed by sulphapyridine than is the *Strep. viridans*. The outstanding problem, however, in the treatment of subacute bacterial endocarditis is the inaccessibility of the organisms in the heart valves rather than the sterilization of the blood stream, and it is probable, therefore, that, as has been argued above, cases in which the infecting organism is a *Strep. viridans* will also show a good response to similar treatment.

Summary

Published cases of subacute bacterial endocarditis treated with sulphapyridine and heparin and with sulphapyridine alone are reviewed briefly.

The encouraging results in those cases treated with sulphapyridine alone are noted.

A scheme of treatment is suggested, and a case so treated with considerable benefit is described and briefly discussed.

I am indebted to the Department of Health for Scotland for permission to publish this case. My thanks are also due to Dr. A. A. F. Peel for helpful criticism throughout.

HYPERVENTILATION TETANY IN TROPICAL CLIMATES

BY

ALEC WINGFIELD, M.D., M.R.C.P.

Physician with Charge of Out-patients, Seamen's Hospital; Physician Emergency Medical Service

It seems clear that tetany is only one of the many clinical manifestations which can result from hyperventilation. The early experimental and clinical observations of Haldane and Poulton (1908), Vernon (1909), Henderson (1909-10), Hill and Flack (1910), Henderson and Haggard (1918), Collip and Backus (1920), Grant and Goldman (1920), Davies, Haldane, and Kennaway (1920), Barker and Sprunt (1922), and Goldman (1922) established the importance of hyperventilation as a cause of tetany, and the subject has been widely discussed in recent years. Its literature has now become tremendous, but an excellent review of the then known facts was published by Thomson and Collip in 1932.

It is now recognized that there are many aetiological factors, of which psychic changes and pain would seem to be the most important. McCance (1932) showed that in certain persons tetany could be induced by attacks of overbreathing which were scarcely perceptible to casual observation; he considered that these persons must be peculiarly susceptible to an alkalosis. It is widely agreed that there are great variations in individual susceptibility to hyperventilation, and in this connexion the work of Schultzer and Lebel (1939) is of interest. Serum calcium is generally accepted to be normal in these cases, while Fowweather, Davidson, and Ellis (1940) have shown that immediately after the attack the serum inorganic phosphorus may be considerably below the normal level. All the evidence at present goes to show that overbreathing produces an alkalosis by washing out carbon dioxide from the blood. The mode of production of tetany by alkalosis is still in doubt. The conclusion of Fowweather and his colleagues (1940) that it is due to tissue alkalosis seems to be fairly well founded.

Effect of Temperature upon Ventilation

Bazett and Haldane (1921) described the effects of the immersion of four men in hot baths for a long period. They noted that sweating occurred early, and that a rapid rise of temperature produced hyperpnoea, which was accompanied by faintness, mental confusion, and tingling. They also observed that these symptoms could be relieved by breathing mixtures containing high percentages of carbon dioxide. The secretion of a large amount of highly alkaline urine was also recorded. This work was confirmed by Landis and others (1926), who noted the occurrence of tetany and found that the degree of change in the blood *p*H did not appear to be in direct relation to the onset of tetany. One of the cases recorded by McCance (1932) was that of a nursing sister whose first and only spon-

taneous attack occurred in an operating theatre, where the temperature may have been considerably above the normal met with in this country and where the clothing is often excessive.

It is a little surprising that no work appears to have been done upon the subject of hyperventilation tetany in tropical climates. In this connexion the following case report is of interest.

Case Report

A ship's engineer aged 27, in good general health, gave a history that while in intense heat in the Persian Gulf he suffered from profuse perspiration leading first to tingling and cramps and, after "a few minutes," to spasm of hands and feet. He was seen by a doctor after this attack, and was found to have a slow pulse but no other abnormal physical signs. He reported that a similar attack had occurred in a hot climate seven years previously. It was thought that the tetany might have been produced by hyperventilation, since the conditions appeared to resemble closely those produced experimentally by Landis and others (1926). He was therefore instructed to breathe quickly and deeply, and after approximately two and a quarter minutes he reported that tingling of the hands and feet had started; overbreathing for a further thirty seconds produced a typical *main d'accoucheur*. The blood calcium was determined almost immediately after this and gave a value of 8.3 mg. per 100 c.cm. On subsequent occasions two further attacks of tetany were deliberately produced. The resting blood calcium on another occasion was 9.7 mg. per 100 c.cm., and the blood chlorides estimated at the same time were within the limits of normal.

Discussion

The identity of attacks of tetany produced by deliberate overbreathing and of those which occurred spontaneously in the Persian Gulf seems certain. This appears to be the first clinical description of overbreathing tetany due to heat. Further investigation will probably lead to the recognition of more cases due to this cause.

I wish to record my thanks to Dr. Arthur Davies for the pathological investigations, and to Dr. R. A. McCance for his very helpful criticism.

Medical Memoranda

Paralysis accompanying Herpes Zoster

The articles by Drs. Barham Carter and J. B. W. Dunlop and by Major Spillane in the *Journal* of February 15 (pp. 234, 236) prompt me to record two cases from my practice.

Case 1.—An active, healthy, and muscular man aged 70, who had been subjected to great anxiety in August, had intense pain of right fifth cervical distribution for three days, culminating in a typical eruption of herpes zoster on September 16, 1940. On the 19th two complications ensued; first a generalized rash which became vesicular and indistinguishable from varicella; secondly, weakness of the right shoulder and arm. The chicken-pox rash ran a normal course, the patient being very ill for two days. The paralysis was complete in the deltoid, biceps, brachialis, triceps, scapular muscles, and clavicular head of the pectoralis major. The forearm and hand, including the brachio-radialis, were unaffected. After consultation with Dr. Booth of Wolverhampton with reference to treatment, a radiograph was taken on November 7; this showed advanced osteo-arthritis of the cervical vertebrae, particularly of C3, C4, C5, and C6. Examination on March 3, 1941, revealed a fairly strong triceps (this showed early improvement) and definite though very weak contraction in the biceps. The paralysis of the deltoid and infraspinatus muscle is complete and seems unlikely to recover.

The features of this case are: (1) the severity of "infection" evinced by the varicella; (2) the association of three factors similar to those in Case 1 of Drs. Barham Carter and Dunlop—namely, posterior root ganglion infection, marked osteo-arthritis of the neighbouring vertebrae, and infection of the grey matter of the corresponding spinal segment. It seems to me that the infection is not likely to spread to the cord except in the presence of an accessory factor.

Case 2.—An active man aged 75 had intense pain over the right side of the face and head for three days, followed by a typical herpetic eruption over the area supplied by the second and third divisions of the fifth nerve on March 1, 1941. There was some vesiculation in the external auditory meatus, but no evidence of otitis media. This was followed by a typical right Bell's palsy on March 4, but I am unable to say if the taste sense of the right half of the tongue was affected. This case followed so closely the course of those reported by Major Spillane and later by others as to need no comment. It does, however, help to outline a definite clinical entity which seems not to be excessively rare at the present time.

Acute Intestinal Obstruction caused by Twisted Ovarian Cyst

The following case is reported because it presents some unusual features.

CASE REPORT

The patient, a 7-para African woman, was admitted to the Bahamas General Hospital on November 3, 1940, with a history of absolute constipation for six days, neither faeces nor flatus having been passed for that time. There had been vomiting for four days, the vomitus still being clear on admission to hospital. The abdomen was distended and tympanitic. There was no visible peristalsis. The temperature was 98.4° F., the respirations 40, and the pulse 160. A turpentine enema produced a few scybala, the return otherwise being clear. Rectal and vaginal examinations showed the rectum to be quite empty following the enema. A diagnosis of acute intestinal obstruction probably due to a volvulus was made.

Under spinal anaesthesia the abdomen was opened by a subumbilical paramedian incision through which the distended intestines immediately protruded. 1 c.cm. of pitressin somewhat reduced the trouble due to the distended gut. The abdominal cavity contained a small quantity of blood-stained fluid and a few small blood clots. Further investigation revealed a plum-coloured necrotic mass in the pelvis; this was identified as an ovarian cyst which had twisted on its pedicle and involved the corresponding Fallopian tube. The tube and ovary were removed *en masse*, and the abdomen was closed in layers. Ephedrine sulphate, 1/2 grain, was given subcutaneously, followed by 1 c.cm. of pituitrin. The patient's condition was poor at the termination of the operation, and on return to the ward 1,000 c.cm. of a 5% solution of glucose in normal saline was given intravenously. The next day she began to pass flatus per rectum, and thirty hours after operation a spontaneous bowel movement took place. Neoprontosil in doses of 5 c.cm. was given daily for three days. Convalescence was uneventful, and the patient was discharged fifteen days after admission to hospital. The cyst was an ovarian dermoid containing the usual greasy material and hair.

It would seem that the obstruction was caused by a reflex nervous paralysis of the lower part of the gut due to the twisting of the ovarian pedicle. Later, absorption of toxins from the strangulated and necrotic tubo-ovarian mass and from the distended and inactive intestines would have tended to aggravate the condition.

SOME OF THE PRODUCTS OF

GLAXO LABORATORIES

A PAGE FOR YOUR REFERENCE

PRODUCT	DESCRIPTION	FORM
ANTIVIRIN Antivirus preparations	Prepared in jelly and liquid forms from cultures of streptococcus, staphylococcus and other organisms. The jelly is for use from the tube in easily accessible infections; the liquid for irrigation of deeper-seated lesions. In the treatment of boils, sinuses, abscesses, carbuncles running ear, infected wounds, etc., when direct contact between the lesion and the corresponding anti-virus is obtainable, antivirus therapy is dramatically effective.	The jellies in long-nozzle or collapsible tubes, the liquid in 30 cc. bottles.
FLAVOGEL Acriflavine Jelly	Flavogel presents acriflavine (1 in 1,000) in a water-soluble jelly base smooth and soothing in action. Intimate contact between wound and tissue is achieved with maximum bactericidal effect. For use on all wounds whether infected or not. Flavogel does not cause pain, and minimises tendency of dressing to stick to the wound.	½ oz. tubes, 16 oz. jars.
GLUCODIN The reinforced Glucose	GlucoDin, the original preparation of glucose, vitamin D and calcium glycerophosphate, has long been successful for the prevention and treatment of ketogenic disorders such as travel-sickness and fat-intolerance and for providing immediate energy without taxing the digestion. GlucoDin replenishes glycogen reserves, supplies the carbohydrate essential to fat metabolism and helps to normalise calcium and phosphorus metabolism.	1 lb., 3 lb. and 7 lb. tins.
LEVU-CALCIN Calcium Levulinate	A sterile aqueous solution of calcium levulinate for parenteral use in all conditions needing urgent calcium therapy. The solution is stable. It has been used with marked success in pre- and post-operative treatment for preventing haemorrhage, inflammatory and allergic conditions with exudation, and hepatic insufficiency. For intra-venous or intra-muscular injection.	Boxes of 3 x 10 cc. (20%) & x 2 cc. (15%)
MINADEX Mineral Vitamin Tonic	An enjoyable reconstructive tonic composed of three groups of therapeutic agents. Each fluid ounce contains: Ferri et Ammon. Cit. Vir. 13½ gr. Mang. Glycerophosph. 1/25 gr. Cupr. Sulph. 1/25 gr. Pot. Glycerophosph. 1/5 gr.; Calc. Glycerophosph. 2 gr. Sod. Glycerophosph. 1/10 gr.; Vitamin A. 18,000 i.u.; Vitamin D. 3,000 i.u.	6 oz. and 12 oz. bottles, and 80 oz. winchesters.
OSTERMILK Successful Infant Food	The successful dried milk food. The proportions of protein, carbohydrate and fat are carefully adjusted and standardised. The curd is light, extra vitamin D is added in stated quantity, the added iron content is three times that of milk. Ostermilk No. 1 is modified for the first three months. No. 2 full-cream is for the later months.	16 oz. tins.
SOLANTOIN Anti-convulsant	For the treatment of severe, inveterate, unresponsive epilepsy. Solantoin is the Glaxo preparation of the anti-convulsant sodium diphenylhydantoinate. Non-depressant. To be given alone or with a nightly dose of the usual anti-convulsant. Dose is one to three 0·1 gram tablets daily.	Bottles of 25, 100 and 500.
G.L. AMPOULES	The range of potent drugs available in G.L. ampoules covers a wide field. The ampoules have several advantages. They open quickly, cleanly and without splintering. A wide, smooth mouth is left for the entry of the syringe needle, and the ampoule stands firmly on its base. The prices are considerably below those usually prevailing.	Full list available on request.

FOOD and VITAMINS

The regimenting of diet in wartime gives new and special significance to the fact that, apart from being the richest natural source of vitamin B_1, Bemax is a food of high protein and mineral value. The usual helping of Bemax (one tablespoonful) provides not only the protein equivalent of beef and the calorific value of cheese, but also the high vitamin content of approximately 200 I.U. vitamin B_1 (400 I.U. per oz.) which has given Bemax its outstanding position as a dietary adjunct. *No other food is as rich in vitamins as Bemax.*

To use Bemax as the first course at breakfast involves little, if any, increase in the household expenditure. In present circumstances the advantage of ensuring adequate vitamin B_1 in this way rather than by supplementary dosing with B_1 concentrates, is apparent.

The Vitamin and Nutritional Constituents of BEMAX

The Vitamins in BEMAX	*The Food Constituents of* BEMAX		*The Minerals in* BEMAX	
A. 280 i.u. per ounce (estimated as carotene)	Protein	34.0%*	Calcium	0.058%
B_1. (aneurin) 1.2 mg. (400 i.u.) per ounce	Digestible Carbohydrate	46.5%	Phosphorus	1.11%
B_2. (riboflavin) 0.9 mg. per ounce	Fat	8.5%	Iron	0.0047%
P.P. factor (nicotinic acid) 1.1 mg. per ounce	Mineral Salts	4.5%	Copper	0.0015%
B_6. (adermin) richest source	Water	5.0%	Magnesium	0.31%
E. (*a*-tocopherol) 7-10 mg. per ounce	Cellulose (fibre)	1.5%*	Sodium and Potassium	0.64%
			Chlorine	0.017%

* *Note the exceptionally high protein and low fibre content.*

Dental Disease —

a manifestation of dietary deficiency?

The remarkable correlation of the incidence and spread of dental disease with demonstrable deficiencies in the diet has been amply confirmed by recent nutritional surveys.

Deficiencies of vitamins and minerals are almost always multiple, which makes it particularly desirable, when prescribing dietary supplements, to achieve a proper balance between the various factors. Complevite provides, in tablet form, a *complete* dietary supplement scientifically balanced to compensate for the actual known deficiencies in the average diet to-day, thus bringing the total intake of the important vitamins and minerals up to the optimum daily requirement of the human body.

COMPLEVITE

VITAMINS A, B_1, C and D
CALCIUM, IRON, PHOSPHORUS
AND TRACE MINERALS

Reviews

OPERATIVE GYNAECOLOGY

Gynaecological Operations. By J. Lyle Cameron, M.D., F.R.C.S., F.A.C.S., M.R.C.O.G. Oxford Medical Publications. (Pp. 200; illustrated. 21s. net.) London: Oxford University Press. 1941.

"The purpose of this book is to present the technique of gynaecological operations as clearly and concisely as possible, giving the indications and contraindications, and pointing out difficulties, dangers, and complications against which the surgeon must be warned." This quotation from the preface makes clear the task the author set himself to accomplish. He has arranged his material into five chapters, which deal with pre-operative investigations, vulval operations, vaginal operations, cervical operations, and abdominal gynaecological operations. A comprehensive index is provided and makes reference easy, the more so as all main headings in the text stand out clearly in heavy type.

The opening chapter on pre-operative investigations includes short sections dealing with general and local preoperative treatment in which the author records what is presumably the routine he adopts for his own cases, but alternative methods of preparation are not given much prominence. A surprising mistake which escaped the editorial pen is found on page 5, where a famous antiseptic is spoken of as "Boney's violet-green solution." Chapter 2 summarizes vulval operations and deals with the indications for operation and the technique advised, together with a short note on the dressings and after-care. Chapter 3 discusses vaginal operations under similar headings, and includes a particularly clear account of the variations of technique in vaginal hysterectomy as well as an account of the McIndoe operation for congenital absence of the vagina. Chapter 4 deals with cervical operations and includes a useful concise discussion on uterine perforation and its treatment.

Abdominal gynaecological surgery is discussed in the last two chapters. The advice given on drainage will not be widely accepted, for there are few gynaecological surgeons who would accept the statement that drainage is advisable after posterior wall myomectomy, the division of adhesions, or the removal of inflamed appendages. The complications of abdominal surgery are well summarized and are grouped as those common to all operations and those most likely to occur after individual ones such as hysterectomy and myomectomy. Illustrations are not numerous, but are for the most part well chosen and are beautifully drawn and produced.

The task the author set himself has been well accomplished, and yet there is something not completely satisfying about the book. Possibly it is that one wonders whether there really is such a thing as "the technique of gynaecological operations." There are different schools of thought and practice in this as in all branches of surgery, and technique is not the monopoly of any one of these. Probably, however, dissatisfaction springs from a deeper source. For whom is the book intended? Much of its contents will be valuable to the medical student, but as he is seldom expected to have more than a superficial acquaintance with operative technique the book is not likely to commend itself widely to the undergraduate. Few general practitioners will be interested in a volume of this nature, and the young gynaecological consultants will find it too elementary to be of much assistance. The book could be expected to make its greatest appeal to the general surgeon who is obliged to perform gynaecological operations, but fortunately with the increasing influence of the Royal College of Obstetricians and Gynaecologists this branch of surgery is being entrusted more and more to those men who have been specially trained to perform it. One's disappointment, therefore, is probably due to the suspicion that a book which would have been heralded as a good one ten years ago has unfortunately arrived a little too late.

CARE OF SICK CHILDREN

A Textbook on the Nursing and Diseases of Sick Children for Nurses. By Various Authors. Edited by Alan Moncrieff, M.D., F.R.C.P. Third edition. (Pp. 640; 142 illustrations. 21s. net.) London: H. K. Lewis and Co., Ltd. 1941.

It might have been thought that this book would fall between two stools, that it would contain too much information for a nurse and not enough for a doctor. The appearance of a third edition, however, evidently shows that it meets a want. In the present edition, which is fifty pages longer than the last, the whole book has been thoroughly revised and new methods of treatment are adequately described. It is a little surprising, however, to find that in the treatment of meningococcal meningitis the use of sulphapyridine is given less space than that devoted to anti-meningococcal serum, although it is admitted that the new drug is replacing serum treatment—surely an understatement. In the appendix on the action of drugs, too, sulphanilamide is included among drugs "affecting the circulation," which is hardly where a pharmacologist would class it. A new chapter on children in the Tropics, by Lieut.-Colonel Vere Hodge, is a valuable addition to the book, and the same may be said of the appendix by Miss D. Lewis describing briefly methods of physiotherapy. The illustrations, always excellent, have been considerably increased in number, and altogether the new edition will enhance the already great popularity of the book among both children's nurses and paediatrists.

MEMORIES OF A CORONER

Inquest: A Coroner Looks Back. By S. Ingleby Oddie, M.B., C.M., Barrister-at-Law, formerly H.M. Coroner for Central London. (Pp. 255; illustrated. 10s. net.) London: Hutchinson and Co. (Publishers), Ltd. 1941.

To be coroner for Central London for half a life-time must obviously give the raw material for many exciting books, and Mr. Ingleby Oddie has made good use of an outstanding opportunity. He recalls and illuminates most of the first-class sensational murders and accidents of the period. In fact, he goes back to 1888 and gives, at second hand, a full account of the ghastly "Jack the Ripper" crimes, on which he was informed by the contemporary police surgeon for the City. His own career in the legal handling of crime began with the Crippen case, in which he held the junior brief for the Crown. While still at the Bar he was also concerned in the trial of Steinie Morrison, the "Clapham Common murderer." After he became a coroner in 1912 sudden death in innumerable grisly forms, sometimes merely sordid and sometimes highly dramatic, was his daily fare. His selection from his records of these inquests is miscellaneous in the widest sense, but among its particularly interesting items is his reminiscence of the cocaine case, in which the young actress Billie Carleton, a drug addict of 22, was found dead, and which disclosed the scandalous traffic in drugs which existed in London just after the last war. This case was probably one of the most important single factors in the passage of the first Dangerous Drugs Act. Mr. Oddie relates the inquest on Field-Marshal Sir Henry Wilson, who was shot by two Sinn Feiners on his own doorstep; on the victim of the trunk murder of 1927; on ten persons drowned in base-

ment bedrooms by the overflowing, on an exceptionally high tide, of the Thames at Westminster in January, 1928; on the workman who was killed in the gas explosion which blew up a large part of Bloomsbury some months later; on Vera Page, the little girl whose violator and murderer was never brought to trial; on the unhappy gentleman who insured his life heavily and deliberately shot himself in a taxicab for the benefit of his creditors, and set on foot an expensive leading case on the liability of the insurers of a suicide; and on a host of other victims. The times in which we live give a new interest to his account of the case in which two soldiers, part of the escort of a deserter, shot a man dead as he attempted to escape; and of the bombing of Odhams Press building, in the basement of which a large number of persons were crushed by falling masonry and machinery. (That disaster, which was front-page news for two or three days when it happened in the last war, would pass almost unnoticed to-day.) In between these high lights come numerous smaller but equally interesting recollections.

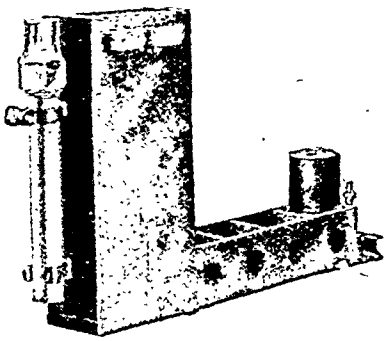
This book, written by one of the most capable coroners of his time, illustrates clearly the merits and defects of the coroner system. Mr. Oddie has an admirable and varied background of public school, the Naval Medical Service, and the Bar. His book is modest and objective and by no means without humour. It therefore all the more strikingly reveals his almost complete lack of insight into criminal psychology. That is not necessarily a defect in a coroner, whose business is to find out the circumstances in which death occurred; but it is typical of the era in which he worked, and the end of which saw an advance in criminal psychology greater than any that had been made during the previous century.

Notes on Books

Textbook of Pharmacology for Nurses, by Profs. MARGENE O. FADDIS and J. M. HAYMAN, jun. (J. B. Lippincott Company: 15s.), is written with the object of explaining to nurses not only the technique of administering drugs correctly but also the nature of the effects they are intended to produce. A simple but clear account is provided of the mode of action of drugs and the illustrations and charts are very well chosen. An interesting feature of the volume is a chapter on the protection of the public in its use of drugs and cosmetics. This gives a short account of the U.S. Food and Drugs Acts.

Herb Gathering, by BARBARA KEEN and JEAN ARMSTRONG, is a booklet which describes the gathering of plants for medicinal use (London: Brome and Schimmer; 9d.). The authors give a few pages of excellent practical instructions for the collection and drying of plants, and this is followed by descriptions, with illustrations, of about sixty plants. It is rather surprising to learn that so many of our native plants find a use in herbal medicine.

Preparations and Appliances



EMERGENCY HYPODERMIC OUTFIT

Dr. M. W. GEFFEN (Hampstead, N.W.3) writes:

Some weeks ago doctors were asking for a method of carrying hypodermic medication in a form suitable for immediate use in air-raid or similar emergencies. The outfit here illustrated has been designed by me with the assistance of Messrs. Allen and Hanburys, who hope to have it available immediately.

It consists of a strong japan-enamelled metal case with attached hypodermic syringe (in separate metal spirit-proof case), and contains four compartments holding rubber-capped bottles of hypodermic solutions. The over-all measurements of the case are approximately 6 in. by 3 in. by 1½ in. It may be carried in a coat pocket, but is also provided with lugs to take a shoulder-strap and a strap round the chest, the latter to prevent swinging and banging when crawling over debris etc.; moreover, the straps leave both hands free. The case opens on a hinge, and when it is open the four bottles and the syringe are all upright. The rubber caps of the bottles are further protected by screw-on covers, but it is recommended that these be removed (and left behind or pocketed) and the rubber caps wiped over with spirit before the outfit is taken to an incident.

The syringe case is attached to the outfit by screw clips and can be removed or changed at will, but cannot fall loose its cover can be removed without detaching the case. A chain connects the cap of the syringe case to the body of the case to prevent the cap from being lost or from requiring to be

held. (This is not shown in the illustration.) There are also two spare needles held in the case of the outfit by a clip. The solution bottles are held from slipping or falling in any circumstances, but finger-holes in their containing compartments allow of their easy removal when desired.

The solutions carried may be varied according to individual judgment, and the makers are preparing a range of these of standardized strengths. My own suggestions are: (1) morphine sulphate, 1/3 grain per c.cm.; (2) omnopon (or allopon) 1/3 grain with hyoscine 1/150 grain per c.cm.; (3) coramine, or similar analeptic; and (4) either strychnine 1/30 grain per c cm., adrenaline hydrochloride, or morphine sulphate 1/6 grain per c cm. (for children). The solutions being standardized and the syringe a 1.0 c.cm. Record, one syringeful, even in the dark, is one standard dose. The No. 2 solution of omnopon (or allopon) with hyoscine was suggested to me by Dr. J. E. Piercy of the New End Hospital, Hampstead. He recommends it for use in cases where pain and shock exist together and early surgical treatment may be required. The pain will be relieved by 1.0 c.cm. without the drop in blood pressure that usually follows heavy doses of morphine and, if necessary, injection may be renewed after two hours to control return of pain or restlessness without unfitting the patient for an anaesthetic. One caution is necessary: the doctor must either memorize the positions of his bottles, or, if he marks them with luminous paint, must expose the paint to light occasionally. Of course, the bottles may be marked with raised or embossed labels.

A patent has been applied for.

MICHEL SKIN CLIPS

The metal skin clips designed by Dr. Paul Michel, and known by his name, were originally made in France and afterwards in Germany. They have for many years past been used throughout the world for closing skin incisions, and now that the supply of the original make has been cut off Allen and Hanburys have installed the necessary tools and machinery for their manufacture in this country. The material of which they are made is exactly the same as that of the original French clips, and all sizes, 12, 14, 16 and 18 mm., are available.

The improved Michel clips known as Kifa skin clips were originally of German manufacture, though marketed by a Swedish house. Allen and Hanburys have installed machinery for these also and they are now available.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JUNE 21 1941

DEVELOPMENT OF THE MALIGNANT TUMOUR

Recent studies of the genesis of cancer show that the process is often more gradual than was once thought, and that its real beginnings lie far back in what has usually been regarded as a precancerous period of wholly non-specific hyperplasia. This is seen most clearly from a series of ingenious experiments described in papers from the Rockefeller Institute, one by Rous and Kidd[1] and the other by MacKenzie and Rous[2]; and support is forthcoming from other recent and earlier studies. The Rockefeller workers, using the rabbit's ear, have again investigated the beginnings of tar tumours. They find that if painting is completely discontinued at the end of a month or so, no changes are seen beyond a slight non-specific inflammation, and perhaps here and there the suggestion of an early papilloma. Soon these disturbances subside, and, in the absence of further treatment, the ear will thenceforth remain free of papillomas; yet some of the epithelial cells have already received that special, specific, and irreversible bias which determines that when favourable conditions arise they or their descendants will become cancerous. If within a few weeks or months the painting process is renewed, thus providing the necessary favourable conditions, some of these biased cells now proliferate and form papillomas; this occurs even in areas where no sign of papilloma has previously been found. The abnormal tendency to multiplication and tumour formation shown by the affected cells is still dependent on the continued presence of the tar; if the tar is withdrawn the papillomas steadily dwindle, until ultimately even microscopical examination may fail to reveal any persisting tumour cells. If the tar is applied once more one or several of the papillomas may again appear. The successive disappearance and reappearance of a particular papilloma may be demonstrated in this way, but each time it reappears more promptly and becomes quiescent more slowly. Stroma changes, too, are more persistent. Eventually there is no retrogression even if tarring is completely stopped: the exhibition of the cancerous tendency no longer depends on coexisting favourable conditions, and the cells are obviously malignant.

Not all papillomas follow this course. Many disappear by the way, many appear late, and some pass more directly into the fully cancerous condition. Cells vary among themselves, and at any one time those in different parts of a papilloma may show different degrees of malignancy. Rous and his colleagues are struck, first, by the occurrence of these latent cancerous cells, indistinguishable from normal cells; and, secondly, by the continuity of the transition from these normal-looking cells up to the most malignant. If the tarring goes on indefinitely there is, according to the typical process visualized by Rous and his colleagues, an orderly progression by imperceptible stages. This same feature of gradualness or continuity has impressed Sir Robert Muir in his recent study of the development of human breast cancers.[3] He describes how, in those relatively few cases in which he could be sure of the facts, a single and continuous process is seen. This moves from the simplest recognizable hyperplasia of the epithelial lining of mammary duct or acinus, through various stages of increasing disorder of growth, on to the frankly malignant condition, and thence to the completely unorganized and anaplastic state. In the Shope skin papilloma—a virus disease of rabbits—there is a similar continuous trend from the early benign wart through stages less well organized to evident neoplasia and even, as before, to the completely unorganized state. This gradual transition appears to be characteristic of epithelial cancers in general and possibly of all malignant disease, though it must be recognized that the genesis of sarcomas is difficult to study, and often, even in cancers proper, the intermediate stages seem to be more or less completely telescoped. Thus the view emerges that the point which in practice is taken as the end of the precancerous period does not mark the initiation of some essentially new and novel process in the cell. It is simply the point at which the tendency to cancer has become so strong that it can no longer be overcome by ordinary bodily reaction. This seems the most reasonable explanation of the apparently critical nature of the end-point of the precancerous period. Rous and Kidd, however, take a slightly different view. They insist on the neoplastic nature of cells in the precancerous period, but think that progress towards unmistakable malignancy occurs in a sequence of numerous steps rather than in a truly continuous manner, the step at the end of the precancerous period often being more abrupt than the others and possibly different.

The experiments of Rous, Kidd, and MacKenzie bring the question of latent cancer again into prominence. It is shown, as explained above, that epithelial cells already capable of producing tumours when given the opportunity may lie quiescent for long periods—six months at least. It is shown also that during this time the quiescent cells are exactly like the corresponding normal cells in both behaviour and histological characters. In this quiescent state they display no invasive qualities, and they are entirely subservient to the needs of the body. They may, for instance, take part in a reparative process and, multiplying, may spread over an adjacent injured area to form a new epithelial covering. The latent capacity to form tumours in favourable circumstances is greater in some cases than in others, and the capacity is transmissible to daughter cells. This has not been proved for sarcomas; but we are faced with the possibility—probability, in fact—that scattered here and there throughout the body there are from time to time quiescent cancer cells ready to flare up into malignant tumours under certain conditions. In some such cells, to judge from the tar experiments, the quiescent state may always have existed; in others it may have supervened only after a period of tumour-forming activity. In human beings the great majority of tumours are already malignant when first observed. They are simply those tumours which, by the activity of the carcinogenic process, or owing to favourable conditions, have survived to attain full independence. For every one of these, if the tar experiments can be

[1] *J. exp. Med.*, 1941, 73, 365.
[2] *Ibid.*, 73, 391.
[3] *J. Path. Bact.*, 1941, 52, 155.

taken as a guide, a multitude must have perished by the way, and there may be some cancerous cells still lying inert. Not so very different, perhaps, are those cells which, derived from clinically observed cancers of human beings, remain indolent over a long period. This must be the case, for example, when metastases light up and are noticed years after the primary tumour has been excised.

MacKenzie and Rous stress the need for distinguishing clearly between factors which cause the primary cancerous bias in cells and those which enable biased cells to manifest their carcinogenic capacities. In tar the two factors are combined: tar initiates the cancerous change, and also provides conditions under which fully malignant growths may come into being. But the two factors are not always thus closely associated. It is possible, for instance, that there may be carcinogens which, when acting alone, fail to produce tumours because they cannot fulfil the second function mentioned; but of such carcinogens nothing is known. Of the other possibility—namely, that some factors exist which are capable only of unmasking the cancerous tendency of already biased cells—we know a little more. In the experiments of Rous, Kidd, and MacKenzie it is shown that epithelial cells which have developed an initial cancerous bias before tarring is stopped, and which have afterwards become quiescent, may flare up and become manifestly malignant if painted with turpentine or when involved in the repair tissue of a healing wound. Neither turpentine nor trauma will of itself produce tumours in normal skin. Deelman observed long ago that the repair of wounds in the tarred skin of mice was often accompanied by the appearance of papillomas and carcinomas at the healing edge of the new scar. Clinical pathologists know that bacterial infection may stimulate tumour growth and increase malignancy. Surgeons sometimes observe that excision of cancers from an expanse of irradiated human skin is followed by the development of a wholly new malignant growth in the healing edge of the wound. Injection of Scharlach R into a benign Shope papilloma may delay regressive changes. The factors so far known to favour increase in malignancy seem all to be associated with inflammation and fibroblastic proliferation. Perhaps the factors discussed above are rather different from those which, attributable to the host, may exert an influence even on frankly malignant cells and so play a part in determining the histological picture.[1] More knowledge is needed on this. Information is also required on the opposite set of conditions—that is, on those bodily factors which tend to prevent the latent cancer cell from multiplying and proceeding to tumour formation. Should it be possible to utilize or enhance the action of these factors, then it may be hoped we shall be in a position to tackle even the more malignant of established tumours.

The observation that cancerous cells can lie dormant and then rapidly become malignant as a consequence of traumatic or other stimuli—never before so clearly demonstrated as in these experiments of Rous and his colleagues—has obvious medico-legal significance. They support the belief that trauma—a fracture, for instance—may provide conditions favourable to the rapid appearance of a clinically observable malignant tumour, and thus, in a legal sense, be a cause of tumours.

But with all these discoveries the essential cause of cancer remains elusive. The specific abnormal tendency to cell multiplication is the basic phenomenon and the substrate on which the various accessory factors operate. We still seek for what lies behind this specific change in cellular activity; and, notwithstanding greater histological and biological knowledge of precancerous and later stages, it is still not possible to visualize the state of affairs in the cell itself. The development of a typical or "textbook" example of cancer is now seen as a continuous and single process extending through the precancerous period and into the period of obvious malignancy. If this view is accepted, and it seems it must be, the outstanding feature is the continuity of the process, the smooth transition from one phase to the next. A long and orderly succession of cell mutations such as would give the required apparent continuity is improbable, and a similarly orderly series of consecutive mutations of a virus seems little more probable. In the absence of direct knowledge of the significant intracellular conditions, discussion of this aspect of the cancer problem is unprofitable. But we are now on a different footing in regard to the initiation of cancerous change. Applications of tar to the rabbit skin result in the appearance first of papillomas and then of carcinomas, and the same holds good for the Shope virus. In one sense, then, both tar and virus may be causes of cancer. The remarkable feature of recent studies is that, with widening knowledge of these two rabbit papillomas, the parallel between them becomes more and more close. Thus in both there is the same increasing disorderliness of growth as the fully malignant stage is approached. Even the occurrence of latent cancerous cells seems in no way peculiar to papillomas induced by tar, for papillomas caused by Shope virus occasionally reappear spontaneously at spots where they have once vanished. Evidently the cancerous condition is the same, whether apparently caused by a physical agent or by a virus. The problem of the moment is whether a virus is present in tar tumours (a reasonable question, as Shope virus, though not directly demonstrable, is known to persist indefinitely in transplanted Shope cancers), or whether there is some other unifying principle to be discovered.

THE EFFECT OF MALARIA ON THE BIRTH RATE

The dominant part played by malaria as a cause of mortality in tropical and subtropical countries is often stressed. It is not so commonly recognized how difficult it is to determine, even approximately, what is the actual mortality due to malaria. One reason for this difficulty is that malarial mortality in indigenous populations of tropical countries is mainly displayed as raised infantile mortality. Hence statistics rarely help us, for a raised infantile mortality is obviously very difficult to analyse into its components. The effect of malaria is not, however, confined to post-natal mortality, for death of the foetus in the form of stillbirths and abortions is a pronounced feature of this disease, and here statistics very rarely give us any information. It is, however, very generally assumed that these antenatal effects, coupled very probably with reduced conceptions, are displayed in a lowered birth rate which is supposed to exist under malarious conditions in a complementary manner to the raised death rate. Nevertheless a number of observers investigating malaria in such circumstances have recorded their opinion that

the birth rate is not lowered and may even be increased. This curious anomaly has never been satisfactorily explained, and the whole question of the birth rate in malaria is a subject regarding which almost nothing is known. Yet it is vitally important, since the relevance of the birth rate to questions of the decay of populations, depopulated tracts, and backward races, as well as to the question, now often raised, of overpopulation, should certain important diseases be effectively controlled, is very evident. It is satisfactory, therefore, to note the recent publication by Colonel C. A. Gill of the results of a very complete and careful statistical inquiry into the influence of malaria on the birth rate, with special reference to Ceylon.[1]

Ceylon has been chosen for the investigation because in the first place the vital statistics of Ceylon are unusually accurate and complete, and, further, Ceylon includes within relatively restricted limits a great variety of malarial conditions. Not only has this island, as many may remember, suffered in recent years from a severe manifestation of epidemic malaria, but it shows sharply defined zones of various degrees of endemic malaria, including non-malarious areas, areas of moderate endemicity, and areas of hyperendemicity. This latter type of malaria is a condition in which the whole population is exposed to such intense malaria that a sort of equilibrium becomes established between intensity of infection and immunity, the brunt of the impact falling especially upon those in the first decade of life, who, as a result, develop an immunity during childhood which enables the adult population largely to escape. The island therefore offers exceptional conditions for such a study as that undertaken by Colonel Gill. The actual facts regarding the effect of malaria on the birth rate were found to be complex, depending on the type and degree of malaria and the nature of the population. In the five zones delimited and numbered by the author according to increasing malarial intensity as shown by the spleen rate, the death rate, both actual and standardized, and the infantile mortality rate progressively increased by substantial increments *pari passu* with increase in the zonal spleen rate. On the other hand these conspicuous changes in the death rate are not associated with any marked change in the zonal birth rate, whether actual or standardized. A study of the corrected birth rate month by month, however, revealed that in Zone 1, the non-malarious zone, births showed a large wave of increase from October to March, with a small increase in May, which may be termed the "spring wave." In the other zones, all more or less affected by malaria, this normal distribution is altered, there being evident a decrease in the October to March wave and an increase in births from April to September. It is this effect due to reduced conceptions, stillbirths, and abortions during the malaria season, thereby liberating, so to speak, more wombs for renewed conceptions in the remainder of the year, which is, according to the author, the characteristic effect produced on the birth rate by endemic malaria. The total birth rate is not reduced.

These findings, the author is careful to explain, relate to the corrected birth rate and assume stable populations. They do not apply, for instance, to a community such as Europeans or other non-immunes, who do not represent the same relation to malaria as do the indigenous inhabitants. Also, indirect conditions brought about by malaria may greatly affect the crude birth rate—for example, in the case where, due to economic effects brought about by malaria, there has been an emigration of those of child-bearing age. Since epidemic malaria occurs only in populations not subject to a high degree of endemic malaria, there is a reduction in the birth rate due to stillbirths, abortions, and reduced conceptions, but this is temporary. That these conditions are not peculiar to Ceylon is shown very strikingly by the observations of Kenrick in Central India, referred to by Colonel Gill. Here, although no explanation is given, statistics based on thirty-three hyperendemic villages with a mean spleen rate of 80%, compared with those of thirty-four villages with a mean spleen rate of 4%, show that the monthly distribution of births in malaria-free ("healthy") districts of the Central Provinces is characterized by a large wave of enhanced births in the autumn, whereas in the hyperendemic area this wave is almost absent and is replaced by a conspicuously large wave in the spring. The mean birth rate of these two groups of villages was respectively 45.6 and 44.6 per mille.

Colonel Gill's results are of interest not only as a much-to-be-desired investigation of an important subject, and as explaining the seemingly contradictory evidence of different observers in regard to the effect of malaria on the birth rate, but also as emphasizing the value of well-organized registration of vital statistics in tropical possessions. Unfortunately not many of our colonies in the Tropics reach the high level of Ceylon in this respect.

BLOOD CLOTTING

During the last seven years there has been a considerable change in views on blood coagulation. In 1934 the position could be summarized thus: when clotting occurs an enzyme converts fibrinogen to fibrin; the thrombin is formed from prothrombin; tissue injury initiates clotting; free calcium ions are essential; and, finally, platelets appear to play a part. Of all these, the blood calcium was clinically the most important, because by the use of citrate or lactate the clotting time might be lengthened or shortened. Since then the position has altered in a number of ways. In the first place some of the elements involved have been obtained in a pure state—notably heparin in Canada by Best and Scott[1] and in Stockholm by Jorpes,[2] and prothrombin and thrombin by J. Mellanby[3] in England. Secondly, there has been the work by Dam[4] in Copenhagen and by Almquist[5] in U.S.A. on the nutritional factor now called vitamin K. Thirdly, emphasis has been laid on the ether-soluble factor by J. Mellanby and Leathes.[6] How blood clotting takes place has been removed from the realm of speculation to that of reasonable certitude. The Morawitz-Fuld hypothesis, modified by Mellanby, is now widely accepted. According to this, thrombin is formed from prothrombin by the joint action of thrombokinase and iodized calcium. The latter is, however, necessary only when plasma or whole blood is being clotted, and not if purified reagents are used. Thrombokinase is formed from the injured tissue, and it is also found in certain snake venoms[7]—for example, Russell viper. In building up this theory Mellanby devised the technique which led to the isolation of prothrombin and thrombin. As a result of this work and the emphasis he laid upon the importance of prothrombin as a normal circulating component of the blood, methods were devised of estimating it at least relatively, such as those of Quick,[8] modified by Reid[9] and by Innes and Davidson.[10]

There were two reasons for this emphasis on prothrombin. First, as the immediate precursor in the blood of the active enzyme, prothrombin became the deciding factor in determining the duration of the change of fibrinogen to fibrin—calcium ions and thrombokinase both being mere fulminators and usually present above their minimal quantities. The second reason was that the vitamin K of Dam was found to act by stimulating the liver to manufacture prothrombin.[11] Apparently prothrombin is normally made by the hepatic tissue. This manufacture depends on two things at least: integrity of the liver structure and a steady supply of vitamin K. The latter has been identified as a naphthoquinone derivative, but certain synthetic derivatives have been shown to have the same action.[12 13] If these substances are administered by the mouth or eaten in the food they are absorbed. Vitamin K is most plentiful in green leaves such as spinach and cabbage, certain bacteria, and in egg-yolk and liver. Absorption of the vitamin is dependent on the presence of bile salts in the intestine.[14] Consequently biliary obstruction is associated with deficient absorption of vitamin K, and so with deficient manufacture of prothrombin. It can best be treated either by giving vitamin K plus bile by the mouth, or by injecting vitamin K or a suitable synthetic derivative alone.[15] The latter procedure is preferable. Under these conditions the effect is controlled by observing the prothrombin time, which is the coagulation time of plasma or blood in the presence of excess of calcium and thrombokinase. The relation shown between the degree of liver damage and biliary obstruction and the coagulation time of the blood, and the possibility of restoring the latter to normal, have enabled the surgeon to avoid post-operative haemorrhage as a possible cause of death.

CAUSTIC PASTE FOR CANCER

One of the earliest means of treating cancer was by the use of chemical caustics applied to such growths as could be reached from the surface. Indeed it is probable that this method is still used by unqualified "cancer curers" in remote places. Dr. F. E. Mohs[1] of Madison, Wisconsin, believing that there were certain virtues in the method, has elaborated it and placed it upon a controlled scientific basis. His experience, following a prolonged experimental laboratory investigation, now extends to over 600 cases. It is obvious, therefore, that his work is not to be ignored through mere prejudice against a treatment which has been abused in the past. Briefly the method consists in the application of an escharotic agent to the surface of accessible cancers for a predetermined time, usually twenty-four hours. The "fixed" tissue is then excised surgically and careful microscopical examination is made of frozen sections. A map is then prepared of the exposed area, and the regions where cancer is still present are again treated with the agent. After a further twenty-four hours the "fixed" zones are again excised and examined microscopically. This process is repeated until a completely non-cancerous plane is reached. The raw area now remaining is allowed to close in, and, with the aid of an epithelial proliferant, closure is said to be surprisingly rapid, the resulting scars being soft and pliable. The particular agent used has been the subject of much experiment. The following formula is the one now recommended: stibuite (as a granular permeant of mineral origin) 40.0 g., *Sanguinaria canadensis* (as an organic agglutinant) 10.0 g., zinc chloride (saturated solution) 34.5 c.cm. Dr. Mohs's article is illustrated by photographs showing the progress and final results of cases of squamous carcinoma of the lips, ears, eyelids, and face, rodent ulcers of the orbit and nose, carcinoma of the parotid, and a basal-celled growth of the anus involving the rectum and buttock. The results certainly look impressive. It is strongly emphasized that the method is suitable for use only in well-equipped clinics under systematic microscopical control. Without personal trial it will be difficult for surgeons to assess its value, and as most of the growths for which the treatment is suitable are radiosensitive it is doubtful whether many will feel inclined to abandon the proved value of *x* rays and radium for a method which is more tedious and destructive. Diathermy, too, is a somewhat similar method of treatment, though microscopical examination of the heat-coagulated tissues requires very special experience if it is to be of value. A point of much importance which emerges from these studies is the frequency with which apparently superficial rodent ulcers in the region of the eyelids extend deeply along the walls of the orbit. This is a fact sometimes not fully appreciated when other forms of treatment are used.

ELECTRO-ENCEPHALOGRAMS OF PROBLEM CHILDREN

The usefulness of encephalography in the study of epilepsy and in the location of tumours has been widely recognized. The association of abnormal waves with other neurological and psychiatric affections, however, has not yielded such definite information. Lindsley and Cutts[1] consider that more detailed and more quantitative analysis of the records is required, as well as standardization based on the examination of large numbers of normal persons. They have investigated four groups of persons: thirty-six normal children of good health and, as a group, above average intelligence; thirty upper-class university students; fifty behaviour problem children; and thirty "constitutionally inferior" children, wards of the State and unplaceable in foster homes. Records were taken from four regions of the head and analysed in accordance with a standard procedure. The behaviour problem children as a group differed markedly from the normal children. Far more of the former exhibited slow waves, below 8 per second. For example, 2 to 5 waves per second occurring during 10% or more of the time were about three times as common in the behaviour problem children as in the normal children. The former also showed a much higher incidence of waves of 5 to 8 per second for 10% or more of the time. The numbers exhibiting higher rhythms did not differ appreciably in any of the four groups. The "constitutionally inferior" children were intermediate. They resembled the normal children in showing few frequencies of 2 to 5 waves per second, and the behaviour problem children in exhibiting a high incidence of waves of 5 to 8 per second (of children showing these frequencies, five were reported to present definite behaviour problems). A "hyperventilation effect" is sometimes produced by overbreathing; this is a continuous series of slow waves or repeated bursts of such waves at irregular intervals. This effect was more often found in the two abnormal groups, and it appeared earlier and persisted longer in the problem children than in

1 *Arch. Neurol. Psychiat., Chicago*, 1940, **44**, 1199.

any other group. This is interpreted as a lower threshold of cortical excitability and a greater sensitivity to disturbances arising in the cortex. The authors conclude that the disturbances of cortical function indicated by the slow waves are probably important factors in the causation of behaviour disorders. They promise a further and more detailed analysis of the clinical records and the electroencephalograms of the problem children. It is to be hoped that the neurological approach to difficult cases, which are usually discussed in purely psychological terms, may lead to clarification.

ANTISEPTICS AND THE BRAIN

There has been a revival of interest and even belief in antiseptics since the war began, and most surgeons are willing to admit that they have some value in both the prevention and the treatment of wound infections. This change of attitude is largely due to the remarkable successes achieved by the local application of sulphonamide compounds in solid form, but its effects have embraced other more or less non-toxic substances, particularly flavine compounds and other dyes, which are now being used more freely, more hopefully, and, perhaps it may be said, more intelligently than in the past. The main objection to applying antiseptics to wounds has always been that they may do more damage than good, and of some of the older ones, such as cresol solutions and mercury salts, this is certainly true. About the effect on exposed tissues of other antiseptics which are neither grossly caustic nor protein precipitants, but are generally supposed to cause some cell damage, too little is known. There is some information based on tissue culture studies and observations on the behaviour of leucocytes *in vitro*, but the crucial test is obviously to apply the antiseptic to an experimental wound and to observe its effect either by histological study or by carefully controlled estimation of the rate of healing. A welcome example of this method of direct investigation is the work of Dorothy S. Russell and Murray A. Falconer,[1] which deals with an important special case—namely, the effect of antiseptics on the brain. They exposed the surface of rabbits' brains and applied antiseptics to them simply by placing a piece of material soaked in the solution in contact with the cortex for ten minutes; in some experiments such material was introduced into a linear incision, or a small amount of solution was injected beneath the cortex. The wounds were then closed and the animal was allowed to live for a period of from one to eight days before the effects of the treatment were examined. From the results as a whole it is clear that the brain is easily damaged; distilled water causes extensive necrosis, and it is evident from experiments with various solvents that any solution applied to the brain should be isotonic, preferably buffered, and neutral in reaction. Most of the antiseptics tested, including those which we are accustomed to regard as relatively non-toxic, produced a severe haemorrhagic necrosis, the illustrations of which, both gross and microscopic, have a highly forbidding aspect, suggestive rather of the effect of a cautery or strong caustic, except that the lesion extends even more deeply. The solutions producing these disastrous results were 0.1% acriflavine however dissolved, 5% dettol in distilled water, azochloramide in triacetin, and eusol. Dettol and similar reagents in buffered saline, organic mercurial compounds, and hydrogen peroxide were somewhat less destructive. The only antiseptic free from these effects, and indeed scarcely distinguishable in its action on the brain from the isotonic buffered saline in which it was dissolved, was 0.1% proflavine; this innocuous quality was approached by another closely related compound, 2:7-diaminoacridine. These are therefore considered to be the best antiseptics among those tested for purposes involving application to the brain.

The contrast between acriflavine and proflavine is striking and unexpected. It should perhaps be more widely known that acriflavine is not a pure substance, but a mixture the composition of which is not constant; its chief advantages are greater solubility and the fact that much of the work on flavines, both clinical and experimental, has been done with it. That it should be so destructive to the brain is surprising, since it has repeatedly been found that leucocytes retain their motility and continue phagocytosis in bactericidal concentrations of it. Discrepancies and disagreements about its properties in the past are attributable partly to the varying properties in different samples. But another factor which must certainly be considered is the varying susceptibility of different tissues to chemical damage. It is a matter of everyday observation that acriflavine solutions do not cause haemorrhagic necrosis, or anything like it, in skin or connective tissues While these findings are of the utmost importance for cerebral surgery, and while an isotonic proflavine solution would probably be equally innocuous in other parts of the body, it should not be assumed that the other antiseptics tested are to be condemned for use elsewhere. A similar study of the effects produced in connective tissue and muscle might yield results less dramatic and more difficult to evaluate, but of equal if not greater service to surgery generally.

THE R.M.B.F.

The accounts of the Royal Medical Benevolent Fund for 1940, just issued, show that the total income, a little over £36,000, was some £5,000 more than the figure for 1939. This increase, however, is entirely accounted for by an adventitious increase in the amount received under legacies, which amount is transferred to the capital funds. Subscriptions and donations have fallen by some £600. On the other hand, although the amount expended in gifts has increased to £15,300 from £14,700, annuities are lower by £1,000, and social service and administrative expenses and expenses on appeals and publicity have been much reduced. In a circular issued to subscribers and donors by Sir Arnold Lawson, the chairman of the Committee of Management, it is pointed out that the economy in working expenses—an economy effected by reduction of staff and non-publication of a full annual report—must be largely counterbalanced by the limits which it imposes on the ability of the Fund, by advertisements and appeals, to keep its needs permanently before the medical profession. In the absence of widely issued appeals the committee places the future progress of the Fund in the hands of its regular subscribers, who, it is hoped, will act as living advertising media. The book value of the Fund's investments stands at just upon £220,000. In the circular letter, which was issued before his death, a tribute is paid to the late Sir D'Arcy Power, who on account of failing health resigned the chairmanship of the Committee of Management, a post he had held for over nine years. The address of the R.M.B.F is now 1, Balliol House, Manor Fields, Putney, S.W.15.

The Trustees of the Lady Tata Memorial Fund announce that, on the recommendation of the Scientific Advisory Committee, they have agreed, if circumstances permit, to make the following awards for research in blood diseases, with special reference to leukaemia, in the academic year beginning on October 1, 1941. Grants for research expenses: Dr. J. Furth (New York); Dr. P. A. Gorer (London); Dr. A. H. T. Robb-Smith (Oxford). Part-time personal grant and grant for research expenses: Dr. W. Jacobson (Cambridge).

CHEST SURGERY IN WAR

This is one of a short series of articles based on lectures given at the British Postgraduate Medical School, Hammersmith

GUNSHOT WOUNDS OF THE HEART

BY

G. GREY TURNER, M.S., F.R.C.S.

Director, Department of Surgery, British Postgraduate Medical School

It is interesting to realize that though wounds of the heart are fatal in the great majority of instances there is undoubtedly a residue of cases, small though it may be, which recover.

In warfare a wound of the heart is seldom an isolated lesion, and is often accompanied by serious damage not only to the thorax but to other parts of the body. In 1920 the late Sir George Makins reviewed the specimens of gunshot wounds of the heart which had been brought together in the War Office Collection at the Royal College of Surgeons. These specimens showed that the heart may be almost blown to pieces or very severely lacerated, and that missiles may pass through the viscus to be lodged elsewhere or be retained in the auricles, in the ventricles, or in the walls of these cavities. Like all war wounds, some are apparently aseptic while others are associated with the severest forms of infection. Since the war of 1914-18 many cases have come to light in which missiles have been retained in the heart and the patients have not only survived but have been able to pursue more or less normal activities years afterwards. Injuries less easy to detect, like bruises, contusions, and superficial lacerations of the heart wall, probably also occur in warfare from bursting bombs, etc, but without external wounds. Such trauma must sometimes be the cause of temporary or even permanent disability.

H. Ryerson Decker (1939) was able to review no fewer than 100 cases in which foreign bodies had been retained in the heart of surviving patients, and of these 65 were either bullets or fragments of shell. In most of these cases the stage of infection had passed and the foreign bodies were located by *x*-ray examination, often long after the casualty. When it has been possible to examine the seat of the lesion at operation or at necropsy the foreign bodies have usually been found safely surrounded by a barrier of strong fibrous tissue (Coutéaud and Bellot, 1914-15), and sometimes with a collection of fluid round about them. The causes of death on the field or soon afterwards are the great severity of the injury, shock, or haemorrhage; and under haemorrhage comes the question of cardiac tamponade. Later deaths are due to sepsis, to embolism, or to associated injuries.

Acute Cardiac Tamponade

Cardiac tamponade is a most interesting condition, but for the moment we are only concerned with the acute variety. In many cases of gunshot wound the missile seems to penetrate the wall of the heart without causing haemorrhage, while in others there is free bleeding. If the blood cannot readily escape from the unyielding pericardium this sac becomes rapidly distended and the volume of the accumulating blood exercises pressure on the veins and, later, on the walls of the auricles. In this way the cardiac action is embarrassed and finally arrested. The rate of development of the tamponade depends on the size and situation of the wound of the cardiac muscle and the ease with which the effused blood can escape, either externally or into the pleural cavity. The symptoms are quite characteristic. After a latent interval of varying duration, which may be as short as ten minutes, the patient complains of oppression at the heart and of fear, and is uncontrollably restless. The countenance, at first pale from shock, becomes cyanosed, the body surface is cold and there is profuse perspiration, while the big veins at the root of the neck are overdistended. The quick pulse becomes irregular, and as the heart falters its beat becomes fluttering in character. Naturally the blood pressure is low and rapidly falls as the patient sinks into unconsciousness. Examination reveals the signs of distension of the pericardium, as shown by the greatly increased dullness, while the heart sounds are muffled and obscure. The condition is rapidly fatal, therefore it must be recognized promptly if effective aid is to be given. The essential step is to open the pericardium freely so that the accumulated blood can escape: the heart requires living room and must be immediately decompressed. Cokkinis says: "Every patient who reaches the theatre with the least evidence of cardiac function should be operated upon, as even in the most desperate case the compressed heart may revive immediately the pericardium is opened."

Of course, if after the release of the intrapericardiac tension the bleeding continues the heart must be exposed in order that the wound may be sutured; for preservation from one sort of haemorrhagic death will bring no credit to surgery if the patient is to succumb from another. Though merely to enlarge an entrance wound may save death from tamponade, it is so likely to be necessary to deal with the wound in the heart itself that the surgeon should be prepared to carry on there and then with the complete operation. The technique to be employed is described below.

Diagnosis of Heart Wounds

The diagnosis of wounds of the heart is suggested by a situation near the cardiac area, but in many cases the wound of entrance has been in the lateral wall of the chest, in the axilla, or even through one or other upper extremity. With a missile impacted in the heart there is very often no characteristic disturbance, and the suspected diagnosis can only be confirmed by radiography. But even the radiograph may be deceptive, for foreign bodies in the pericardium frequently reveal a pulsation which is merely communicated. The only thing to do is to accept the probability of a heart wound when a missile has entered within the cardiac area and not to overlook the possibility with wounds in other situations. The exact diagnosis of the position of the missile will usually be a matter for a subsequent and more detailed investigation. But another type of case occurs in which the wound has destroyed some part of the parietes and there is a direct and obvious communication between the outside and the heart. These open wounds are not necessarily the most grave. Generally speaking, wounds from shell fragments are more serious than those inflicted by bullets, and this is largely due to the common association of sepsis with shell wounds.

Emergency Treatment of Shell Wounds

Perhaps it is better at this stage to deal with the treatment of such wounds as are obvious emergencies; these include the open wound from shell fragments as well as the wound in which cardiac tamponade rapidly

develops. In the open wound the indications are to arrest haemorrhage, to treat shock, and to anticipate sepsis These indications can be met by approaching the matter as with wounds in other situations, and it will be necessary to excise the wound in the parietes, to inspect the heart, to suture any laceration in the viscus which is bleeding, or to remove a foreign body that is easily accessible. Foreign bodies that are deeply embedded in the heart wall or are lying in the heart cavities are probably best left alone at this stage The temptation for the surgeon to go on is very strong, but, generally speaking, deaths are not due to the mere presence of the foreign bodies, and if the patient survives the risks of haemorrhage and sepsis the problem of the foreign body n be considered with deliberation later In this sort f case it is probably wiser to provide for drainage of he pericardium by tube or rubber tissue, which may afely be placed in the lowest part of the sac or even up behind the heart.

Many of those who have recorded otherwise successful interventions in gunshot wounds of the heart have had to regret late deaths from infection and have sometimes expressed the conviction that drainage might have staved off disaster (Ballance). The local use of some antiseptic will follow the practice that may be in vogue at the time, for the heart and pericardium are quite capable of withstanding such treatment The resources of chemotherapy may be most valuable.

The Best Method of Exposing the Heart

The wound of the parietes may be sufficiently extensive to give access to the interior of the pericardium and the injured area of the heart. As a rule, however, these wounds are not big enough to enable the necessary manipulation to be carried out, and some deliberate method of exposure must be adopted If the pleural cavity is already opened the original wound may be freely

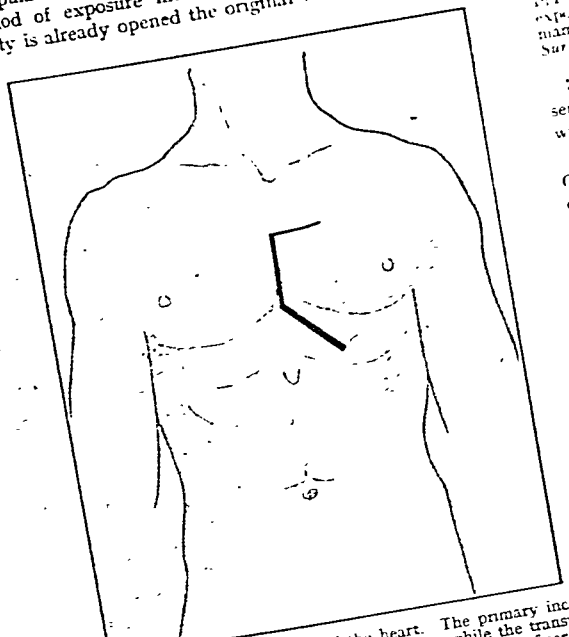

FIG. 1.—Incision for exposure of the heart. The primary incision along the sixth rib is indicated by a broad line, while the transverse cut along the third (or second) rib is represented by a finer line. (Modified from *Textbook of Operative Surgery*, by Theodore Kocher.)

enlarged along the line of a rib. By "spreading" such a wound and enlarging the tear in the pericardium a sufficient exposure may be obtained. But when the pleura is intact it is much better that it should remain so, and in these circumstances the parasternal exposure of Theodore Kocher is very satisfactory. The steps of this operation are as follows:

1. Incise from centre of sternum along the sixth costal cartilage as far as the mammary line.

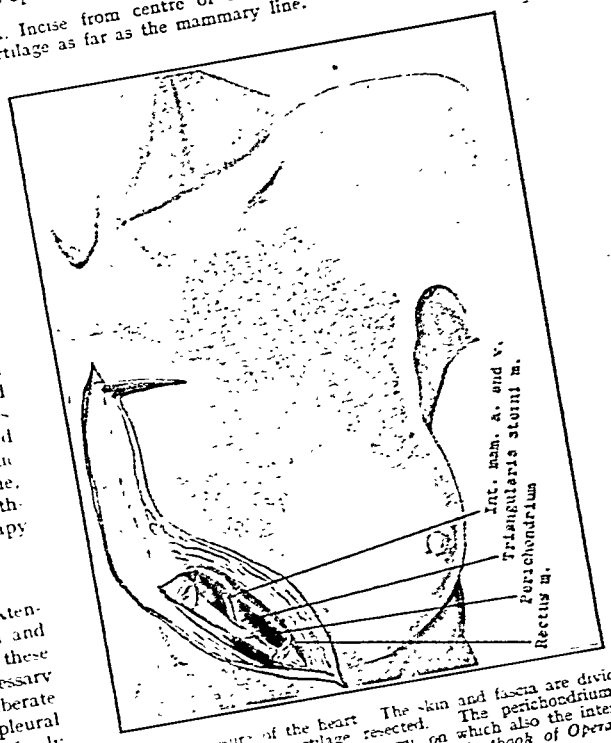

FIG. 2.—Exposure of the heart. The skin and fascia are divided and the sixth costal cartilage resected. The perichondrium is exposed lying on the triangularis sterni, on which also the internal mammary vessels descend (Modified from *Textbook of Operative Surgery*, by Theodore Kocher.)

2. Separate the perichondrium and excise the cartilage. The separation should be begun at the sternal end, the junction with the seventh cartilage being divided.

3. Divide the triangularis sterni muscle close to the sternum. Gently thrusting this muscle outwards will carry the pleura out of harm's way and will expose the pericardium.

4. Open the glistening pericardium either now or at a later stage

5. To secure more room make a vertical incision over the middle of the sternum to the level of the third or even second rib, and a short incision along this rib cartilage

6. Separate the structures from the front of the sternum outwards until costal cartilages are exposed.

7. Divide the fifth, fourth and third cartilages at their inner ends.

8. Lift up the flap of the chest wall with a view to turning it back. Do this slowly and gently, pushing the pleura outwards as the cartilages are lifted

9. Break the cartilages at their junction with the ribs thus exposing a considerable area of pericardium.

10. Open the pericardium along the edge of the sternum and, if necessary, outwards at the lower edge of the exposure.

11. To secure further space use rongeur forceps to cut away the remains of the sternal ends of costal cartilages and, if required, part of the edge of the sternum.

The steps of the operation are shown in the illustrations (Figs. 1, 2, and 3).

The transternal route—splitting the sternum vertically and separating the halves with a spreader—is sometimes recommended, but this is a severe operation and does not seem to have adequate compensating advantages. But whatever method of exposure is employed it will be found that the heart itself is difficult to handle and that the movements prove more embarrassing than would be expected. During systole the walls become stony hard, and the very short diastole gives very little opportunity for palpation. The organ may be pushed to one or other side or may even be partially rotated without interfering with the heart action, but handling about the base or lifting the viscus forwards usually makes the rhythm very irregular and tumultuous or arrests it altogether. Pressure on a spot on the posterior surface of the organ just at the top of the intraventricular septum seems invariably to stop the heart-beat. Lifting the heart forwards in order to expose its posterior surface seems to have the same effect. Allowing the viscus to fall into position and stroking the surface, or applying gentle pressure on the ventricular wall or, if required, more vigorous massage will usually restart the beat. To assist in the process of suturing the viscus a stitch may be placed through the muscle near the apex, where the wall is thickest. If this takes a good hold it will not tear out, and when drawn upon it steadies the heart.

Control of Bleeding.—To control bleeding until sutures can be applied the pressure of the tip of the finger directly on the wound is best. Great care must be taken not to push the finger into the heart cavity. If this method does not suffice a stitch should be rapidly passed into each side of the wound and the ends crossed over without being secured. This will hold the edges together while the final approximating sutures are passed and tied. Furious bleeding—such as might follow accidental tearing of the heart be sutured with 3/0 chromic catgut or fine silk. The stitches should be placed about a quarter of an inch from the margins of the wound and about the same distance apart. They should take a good hold of the cardiac muscle, but should not be so deep as to enter the cavity. It is not necessary to tie them tightly. If bleeding is not arrested one or two superficial sutures may also be used. Oozing should soon cease, but if it does not pressure by the finger for a few moments will probably succeed. A piece of fresh muscle laid over the area will act as a haemostatic patch.

There are many records of successful interventions along these lines, not only with immediate recovery but with complete restoration to health.

On August 6, 1918, René le Fort presented a report before the Academy of Medicine of Paris dealing with a patient on whom he had operated for the removal of a fragment of hand-grenade from the interior of the left ventricle, the patient recovering. At the same meeting le Fort stated that he had removed eleven foreign bodies from the heart in the course of nine operations. In two cases—the one just mentioned and another—the missiles were in the heart cavities. There was only one death in the series.

The Question of Anaesthesia.—In the grievously wounded and severely shocked it may suffice to employ local anaesthesia, and many interventions have been carried out aided by this means alone. The pericardium and the heart itself are said to be insensitive so that it is only a question of infiltration and block anaesthesia for the parietes. But, generally speaking, there is no contra-indication to a general anaesthetic skilfully used. Those who have been brought up in the belief that special anaesthetic apparatus is essential should realize that the many notable operative achievements of the last war were usually conducted under open ether anaesthesia.

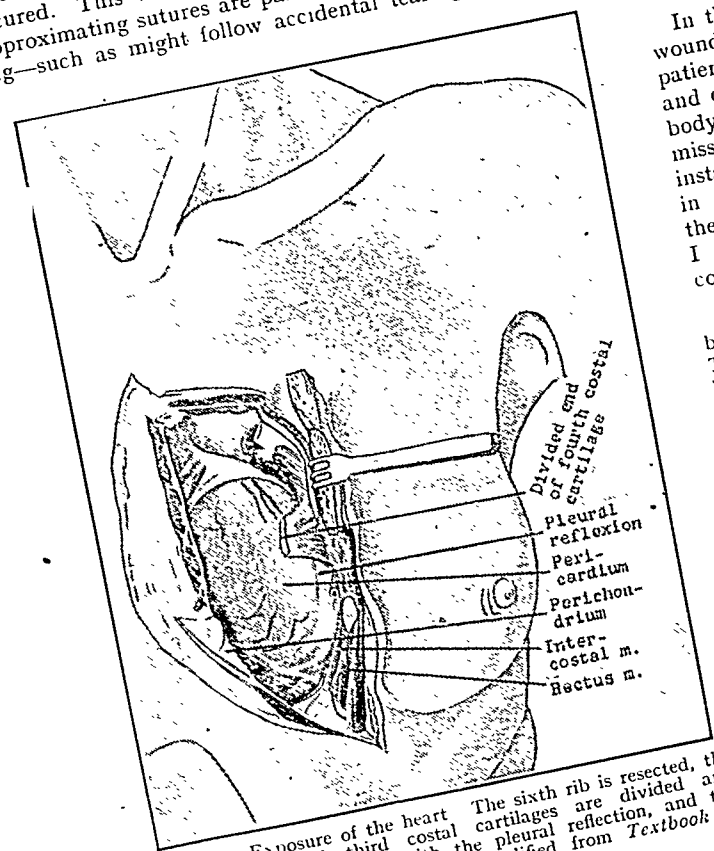

FIG. 3.—Exposure of the heart. The sixth rib is resected, the fifth, fourth, and third costal cartilages are divided and retracted outwards along with the pleural reflection, and the pericardium is fully exposed. (Modified from *Textbook of Operative Surgery*, by Theodore Kocher.)

Missiles Lodged in the Heart

In the group of cases in which there is neither an open wound nor any question of cardiac tamponade the patient will usually make a good immediate recovery, and often without significant symptoms although a foreign body is lodged in the heart. It probably means that the missile has been of low velocity or that it has been, for instance, a spent bullet. There are a good many cases in which such foreign bodies have remained lodged in the heart for some years, apparently without mischief, and I might briefly refer to a case of my own in this connexion.

The patient was an officer, 32 years of age, who was wounded by a machine-gun bullet fired at a range of about 500 yards. There was a snowstorm at the time and the officer had his left hand up to keep the snow from his eyes, and as there was a through-and-through wound just above the elbow it is highly probable that the bullet that lodged in the heart first passed through the arm. In addition it traversed a notebook and a bundle of letters which he was carrying in his tunic pocket. The officer did not appear to have been very severely knocked out after the wound, and when I saw him at the base eighteen days later he was not in any way upset and was rather ashamed that he perforce arrived on a stretcher. The wound of entrance was through the front of the cardiac area and there was no exit. The radiograph showed the bullet in the region of the left ventricle. It was pulsating synchronously with the heart-beat, and in addition there was a whirling movement as if its apex was spinning about in the vortex of the blood stream. After due consideration I made an attempt to remove the bullet, but without success. Now, twenty-four years after the injury, the patient remains perfectly well and is able to live a normal, reasonably active life (*Lancet*, October 19, 1940).

In cases such as the above there is probably little or no haemorrhage from the wound in the heart. The ... may act as a plug as in a case recorded by A. H. ... or the firm contractio... the powerful wall during manipulation—may be controlled by grasping and compressing the base of the heart between the fingers. This is known as the "Sauerbr... ...ip." Wounds should

muscular walls of the ventricles may suffice to stay bleeding. The ultimate fate of these missiles is important as a guide to their management. Though they may remain safely imprisoned in fibrous tissue indefinitely they may be the source of emboli, or may themselves become dislodged and leave the cardiac cavity, forming emboli in the main vessels. Scars associated with such foreign bodies have given way, thus causing the sudden death of the victims. In fact, there appears to be no end to the vagaries of these unwelcome visitors. The immediate symptoms are not always slight, and there may be great cardiac irregularity and irritability and often dyspnœa. As a rule if these symptoms follow directly on the casualty they slowly disappear during a period of months, especially if the environment of the patient is suitable. Much disability may be caused by fear of tragic consequences instilled into the patient's mind or the mere knowledge that the citadel of his well-being is menaced. The fussy attitude of over-zealous relatives and friends, or even the medical attendant, may be detrimental and is to be strongly deprecated. But in some cases, with all the encouragement that hopefulness and the best will in the world can provide, the patient may find that the least exertion brings on cardiac irritability or breathlessness, and for that or other reasons the question of the removal of the foreign body may arise. In these circumstances there is no reason why the possible benefits of surgery need be denied. The matter will have long ceased to be an emergency, and whatever investigations suggest themselves may be carried out at leisure and with proper deliberation. While I would be much opposed to the removal of such a foreign body at all costs, I am strongly in favour of exploration, for the missile may prove to be most fortunately placed for removal and, if not, the wise surgeon can always hold his hand.

Removing the Foreign Body

In the actual intervention the Kocher approach ought to suffice, and especially so if advantage is taken of the additional space which may be secured by removing the costal cartilages right up to the edge of the sternum or even cutting away part of the latter with rongeur forceps. The first problem is to find the foreign body, and that often proves difficult. When the surgeon has finally decided where the cardiac wall is to be incised sutures should be placed on each side of the proposed cut, and he must take care to see that these secure a good hold, as it is by their aid that bleeding will have to be temporarily arrested. The missile must be coaxed out rather than forcibly withdrawn, great care being exercised not to lacerate the heart wall. The defect in the heart must be closed by suture as already described. It is said (Decker) that the mortality from foreign bodies in the heart which are not interfered with is 20%, and that the mortality of surgical intervention is about the same, but it is highly probable that there are some unrecorded operative fatalities which would considerably increase the latter figure.

Foreign Bodies in or about the Pericardium.—These form an interesting group, for the pulsation of the heart is often communicated to them. In some cases they may be associated with sinuses or they may remain safely embedded for years without giving rise to symptoms. Further, they may be the cause of the same sort of disturbances as arise from the presence of foreign bodies in the heart itself. This knowledge justifies exploration in the hope that the missile may be found in a position from which it can be safely and easily removed. In dealing with these foreign bodies it will usually be best to open the pericardium as in the Kocher approach. Even when the foreign body is the cause of a sinus the cardiac movements may be communicated and the discharge lying in the mouth of the sinus may show pulsation. None the less, the proximity to the cardiac region need not deter the surgeon from dealing with such conditions according to established surgical practice.

It has been suggested that missiles in the heart or in the pericardium might be removed under the fluorescent screen, and this method has sometimes been practised by French surgeons. Either through a conveniently placed wound or a small incision suitable forceps are introduced into the pericardium with the idea that the foreign body may be seized and withdrawn under the guidance of the eye. While this method may be feasible with loose bodies or with those only very lightly attached, the consequences might be unfortunate if a missile in the heart wall that was acting as a plug was thus removed. The probabilities of failure would also seem to outweigh heavily the prospects of success. But the method has been successfully employed, and it has this virtue—that, if disaster is not precipitated, the other and more traditional methods can still be employed.

A RESEARCH CHAIR AT THE R.C.S.

We print below a letter signed by the chairman of the Bernhard Baron Trustees and addressed to the President of the Royal College of Surgeons of England announcing a munificent gift for the prosecuting of research in surgery.

DEAR MR. PRESIDENT,

The Bernhard Baron Trustees wish to express their sincere sympathy with the Council of the Royal College of Surgeons of England on the serious loss sustained by the College owing to enemy action. The damage provides yet another example of the indiscriminate nature of the enemy's attacks on the Capital, for the Royal College is far removed from any military objective. The loss will excite the disgust and sympathy of the whole scientific world.

The Trustees are relieved to learn that some of the irreplaceable specimens, particularly those from the unique Hunterian Collection, had been stored in specially reinforced tunnels, and that many of them have been saved.

The Trustees are also gratified to know that the valuable equipment of the Bernhard Baron Laboratories had already been removed to improvised accommodation in the country, where facilities had been installed so that research work should not be interrupted. They are also pleased to learn that the main buildings of the College, including the Bernhard Baron Laboratories, have not suffered structural damage.

The Trustees appreciate that for some time a large part of the financial resources of the College and of the energies of the Council and Fellows will be engaged in the erection of new buildings and the assembling of a collection of specimens which will re-establish the museum and make it once more the most valuable and complete of its kind in the world.

The enemy may destroy our historic buildings and damage our artistic and scientific treasures, but our spirit will remain undaunted. The scientific work which has formed such a notable part of the activities of the Royal College of Surgeons of England must and will continue. The Trustees realize, however, that one of the essential sinews of your and their endeavour to benefit mankind is the provision of funds for the prosecution of research. They have therefore decided to make a gift of £40,000 for the endowment of a Bernhard Baron Research Professorship at the Royal College of Surgeons, so that, whatever the difficulties with which the Council may be faced in other directions, research will not suffer.

The Trustees feel that in offering this gift to the Headquarters of British Surgery they are making a fundamental contribution to the promotion of the ideals which Bernhard Baron had in mind in his many acts of philanthropy—the improvement of the health and the increase of the happiness of his fellow men.

Yours faithfully,

On behalf of the Trustees,
EDWARD BARON, Chairman.
H. W. DANBURY, Vice-Chairman.

London, N.W.1,
June 12, 1941

BIRTHDAY MEDICAL HONOURS

The names of the following members of the medical profession were included in a Birthday Honours List published in a *Supplement* to the *London Gazette* on June 12.

K.C.M.G.

HENRY HAROLD SCOTT, C.M.G., M.D., F.R.C.P. Director of the Bureau of Hygiene and Tropical Diseases, London.

K.C.I.E.

GORDON GRAY JOLLY, C.I.E., M.B., Ch.B., D.P.H., D.T.M., Lieut.-General, Indian Medical Service. Honorary Physician to the King. Director-General, Indian Medical Service.

Knighthood

ALEXANDER STUART MURRAY MACGREGOR, O.B.E., M.D., LL.D., D.P.H. Medical Officer of Health, Glasgow.

PHILIP HENRY MANSON-BAHR, C.M.G., D.S.O., M.D., F.R.C.P. For services to tropical medicine and as Consulting Physician to the Colonial Office.

JOHN SEBASTIAN BACH STOPFORD, M.B.E., M.D., F.R.S. Professor of Experimental Neurology and Vice-Chancellor, University of Manchester.

C.M.G.

JOHN FEARBY CAMPBELL HASLAM, M.C., M.D., F.R.C.P., D.P.H. Colonial Medical Service. Director of Medical Services, Northern Rhodesia.

FRANK SANDLAND HONE, M.B., B.S. For public services in the State of South Australia.

JAMES BALFOUR KIRK, M.B., Ch.B., D.P.H. Colonial Medical Service. Director, Medical and Health Department, Mauritius.

C.I.E.

CODANDA MADIAH GANAPATHY, M.C., M.B., Ch.B. Lieut.-Colonel, Indian Medical Service. Director of Public Health, Madras.

MARK ALLEYNE NICHOLSON, M.B., B.S., D.P.H. Lieut.-Colonel, Indian Medical Service. Chief Medical Officer in Central India and Residency Surgeon, Indore.

CAMERON MACDONALD NICOL, M.D., D.P.H. Lieut.-Colonel, Indian Medical Service. Lately Director of Public Health, Punjab.

HUGH STOTT, O.B.E., M.D., F.R.C.P., D.P.H. Major-General, Indian Medical Service. Honorary Surgeon to the King. Surgeon-General with the Government of Madras and lately Inspector-General of Civil Hospitals, Bihar.

GEORGE VERGHESE, M.D., D.P.H., D.T.M.&H. Lieut.-Colonel, Indian Medical Service. Director of Health and Inspector-General of Prisons, Orissa.

C.B.E. (Civil Division)

ALBERT VICTOR BERNARD, O.B.E., M.D., D.P.H. Chief Government Medical Officer, Malta.

JAMES ALISON GLOVER, O.B.E., M.D., F.R.C.P. Lately Senior Medical Officer, Board of Education.

LIM HAN HOE, M.B., Ch.B. For public services in the Straits Settlements.

JOHN CRAWFORD KNOX, M.B., Ch.B., D.P.H. Honorary Consultant Adviser to the Secretary of State for Scotland in connexion with the Emergency Hospitals Organization.

ARTHUR MASSEY, M.D., D.P.H. Medical Officer of Health for Coventry.

HARRIS MUNDEN MOSDELL, M.D. Secretary for Public Health and Welfare, Newfoundland.

ALBERT WILLIAM SHUGG, M.B., B.S. For professional and philanthropic services in the State of Tasmania.

O.B.E. (Civil Division)

PAUL BOFFA, M.D. District Commissioner, Malta.

Mrs. ETHEL CASSIE, M.D., D.P.H. Senior Assistant Medical Officer of Health for Maternity and Child Welfare, Birmingham.

THOMAS HERBERT DAVEY, M.D. Professor of Tropical Diseases of Africa, School of Tropical Medicine, University of Liverpool. Director of the Sir Alfred Lewis Jones Research Laboratory, Sierra Leone.

ANDREW LESLIE DYKES, M.D. Hospital Officer, Southern Region, Emergency Medical Service.

IAN FRASER, M.D., M.Ch., F.R.C.S. Major, R.A.M.C. Commissioner, St. John Ambulance Brigade, Northern Ireland District.

JOSEPH MARTIN REEVES HENNESSY, L.R.C.P.&S., D.T.M.&H. Lieut.-Colonel, Indian Medical Service. Civil Surgeon, Jubbulpore, Central Provinces and Berar.

HARRY BROWN HETHERINGTON, M.D. Colonial Medical Service. Senior Medical Officer, British Solomon Islands Protectorate.

NARIMAN MUNCHERSHAW HODIVALA, M.B., B.S., D.P.H. Medical Officer of Health, Aden.

THOMAS RITCHIE RODGER, M.D., Ch.B., F.R.C.S.Ed., J.P. Chairman of the Hull and District Juvenile Advisory Committee.

JOHN ALEXANDER SCOTT, M.D., D.P.H. Medical Officer of Health for the Metropolitan Borough of Fulham. For services to Civil Defence.

FREDERICK AUGUSTUS BERRILL SHEPPARD, M.B., B.S., F.R.C.S.Ed. Major, Indian Medical Service. District Medical Officer, Madura, Madras.

HUBERT CECIL MAURICE WILLIAMS, M.R.C.S., L.R.C.P., D.P.H. Medical Officer of Health for Southampton. For services to Civil Defence.

M.B.E. (Civil Division)

EUSTACE HENRY TAYLOR CUMMINGS, M.D., D.P.H. Medical Officer, Sierra Leone.

PAUL THANGASAMI JESU DOSS, M.B., Ch.B., D.T.M.&H., D.P.H. Medical Officer of Health, Secunderabad Cantonment, Hyderabad, Deccan.

Miss ELIZABETH ISABEL HAMILTON-BROWNE, M.B., Ch.M., D.T.M. Women's Medical Service. Lady Assistant to the Inspector-General of Civil Hospitals, Punjab.

BULCHAND SHIVDASANI PARSRAM, M.B., B.S. Medical Officer, R.B. Udhavdas Tarachand Hospital, Shikarpur, Sind.

GEORGE HAROLD TAM THOMAS, M.D. Chinese Medical Officer, Hong Kong.

Kaisar-i-Hind Gold Medal

Mrs. LYDIA TORRANCE ALLEN, M.D., F.R.C.O.G. Superintendent, Lady Dufferin Hospital, Calcutta, Bengal.

British Empire Medal (Civil Division)

TUTU TEKANENE. Native Medical Practitioner (First-class), Gilbert and Ellice Islands Colony.

Among the other Birthday Honours are three which should be mentioned in this column: Viscount Nuffield, a great benefactor of medicine and an Honorary Member of the British Medical Association, is created G.B.E. for public services; Sir John Maude, Secretary of the Ministry of Health, is advanced to K.C.B.; and Alderman Walter Deacon, President of the Pharmaceutical Society of Great Britain, receives the C.B.E.

FACULTY OF RADIOLOGISTS

Presidential Address

The annual meeting of the Faculty of Radiologists was held at 32, Welbeck Street, London, on May 23. The programme opened with the business meeting, at the conclusion of which the president, Dr. S. COCHRANE SHANKS, said that the past year had, regrettably, been one of few activities for the Faculty as a whole. It had been possible to hold only one scientific meeting, but that was a very successful one, considering the times. The adaptability of man was a remarkable phenomenon, and while a year ago the invasion of the Low Countries was enough to cause the cancellation of the scientific part of the annual meeting, this year, in spite of the ordeal of fire and destruction through which the nation was passing, the Faculty was holding scientific meetings and, he prophesied, successful ones. He was glad of this response to the present situation. The late Wilfred Trotter, in that finest of his philosophical writings, *The Herd Instinct in Peace and War*, contrasted the German or "wolfpack" response to this instinct, powerful in attack but weak in disaster, with the socialized response in which adversity engendered a slowly mounting moral determination which was finally overwhelming in its power. This augmentation of the national energy in the face of danger accounted for the change in attitude. It was also the justification for another activity in which he was taking part as the Faculty's delegate—the Planning Commission of the B.M.A. Much criticism had been levelled at this body, but surely, if any planning was to be done, now was the time, when the tide flowed strong, rather than during the ebb of emotions when the war was ended. For then, unless a plan had been completed in major outline, nothing at all would be done. The first duty of the committees which had recently been appointed by the Commission would be to find out the facts. This inquiry would apply to diagnostic and therapeutic radiology as to the other branches of medicine, and at this stage he would need the help of his colleagues. He proposed before long to circulate a questionary among the members of the Faculty, and would ask them to give, under seal of anonymity, such facts about their work in hospital and in private as they felt disposed to divulge; also to give him their views on what alterations and improvements were called for in the radiological services of their district. Later on he hoped that the Commission would set up a radiological subcommittee, with a majority of radiologists co-opted, to design the x-ray services of the country, both diagnostic and therapeutic.

He now had a very pleasant duty to perform—to welcome and formally to admit two distinguished colleagues as Honorary Fellows of the Faculty, Lord Horder and Professor Cohen. Lord Horder needed no introduction from him. Indeed, in the attempt to prepare a eulogy of him he at once suffered from an *embarras de richesse*. But it was particularly as a friend of radiology that he was welcomed and they

AT THE MENOPAUSE

"High Doses of Oestrin are usually unnecessary, at any rate for the commoner menopausal symptoms—such as vasomotor disturbances — and consequently oestrin injections are, fortunately, seldom required. It has been my practice to begin with doses of about 500 I.U. daily by mouth. If this does not control the symptoms the dose is raised to 1,000 . . . this is usually completely effective. There are, of course, certain more severe sequelæ of the menopause, which demand much higher doses . . . Pruritis, Kraurosis, Leukoplakia vulvæ, fall into this class and, provided sufficiently high doses are given, the results are little short of miraculous."

were glad to honour him with the Fellowship. Again it was chiefly as a friend of radiology that they welcomed their second Honorary Fellow, Prof. Henry Cohen of the chair of medicine in the University of Liverpool.

Discussions

The Radiodiagnostic Section, with the vice-president, Dr. E. Rohan Williams, in the chair, then held a discussion on "Gastritis and Duodenitis" in which Dr. F. R Bernridge (Cambridge), Dr. James Dow (St. George's), and Dr. G R Mather Cordiner (St. George's) took part. This was followed by a short paper on "The Association of Short Oesophagus and Peptic Ulcer" by Dr. A. S. Johnstone (Leeds).

In the afternoon the Radiotherapy Section, with Mr. G F. Stebbing in the chair owing to the indisposition of the vice-president, Dr. W M. Levitt, discussed "The Value, Technique, and Limitations of Biopsy." The chief speakers were Dr. R. W. Scarff (Middlesex), Mr Lionel E C. Norbury (St. Mark's), Dr. F. Ellis (Sheffield), Dr F Gordon Spear (Cambridge), Mr. T. A. Green (St. Thomas's), and Dr J R Nuttall (Manchester).

Correspondence

The Darning of Hernias

SIR,—At the present time it is important for reasons of national service that hernias should be dealt with by the simplest, quickest, and most secure method. It is a subject of satisfaction to me, therefore, that the "darn and stay-lace" method which I described in 1918 (*Practitioner*, 1918, **2**, 100, 406), and have used ever since with good results, has received recent endorsement from surgeons of large experience, particularly Souttar, Ogilvie, and Maingot. So far back as 1922 Souttar (*British Medical Journal*, 1922, **2**, 1024) wrote: "The method of darning hernias was, I believe suggested by Sampson Handley in 1918, and I can only attribute the limited use which has been made of it to the absence of a suitable suture material. . . . I have now used mercurialized silk for several years and in no case have I seen any signs of irritation, nor has it ever been necessary to remove the silk." "The advantages of the method are its extreme facility, the avoidance of extensive dissection and of traction with a resulting absence of shock, its applicability to every conceivable form of hernia, and the security of the result."

I must differ from my friend Mr. Souttar on two minor points. The success of the method is not dependent on the use of mercurialized floss silk, excellent though this material may be. I have generally used Japanese silk or linen thread, kept in 1 in 1,000 flavine spirit, boiled before use, and immersed during the operation in watery flavine 1 in 1,000. The impregnation of the suture material with a non-irritant antiseptic is a common-sense precaution which should not be omitted.

There appear to be two reasons why my operation has not been generally adopted. For many years the erroneous impression has prevailed that catgut is a safer suture material than silk. This impression dates from a period when gross infractions of aseptic technique were common, and is now out of date, provided that the silk or linen thread used is the thinnest which will do the work, and that it is impregnated with an antiseptic harmless to the tissues. The groundless fear of unabsorbable sutures is the first reason why the operation has not been widely used. The second is that in 1924 Gallie and le Mesurier introduced the use of fascial strips taken from the patient as sutures to close the inguinal canal. The method is undoubtedly efficient, though complicated and relatively clumsy. As Ogilvie says: "Fascial suture always adds an operation on the leg to one on the hernia," and troubles may arise from the unnecessary thigh wound. The ingenuity of the Gallie operation has caught the fancy of surgeons, and it has been widely adopted. I doubt, however, whether any surgeon who tries my plan, or one of its modifications, will ever return to the Gallie method.

As I have published nothing on the subject since 1918, I may be allowed very briefly to describe the operation as applied to an ordinary indirect inguinal hernia, and to stress the principles upon which it is based.

(1) The external oblique is incised from the external ring to the internal ring. An identification forceps is applied to each cut edge. The sac is then completely removed and the cord retracted upwards.

(2) The posterior wall of the inguinal canal is thus exposed, bounded above by the outer edge of the conjoined tendon and below by the upturned lower margin of Poupart's ligament. A single long thread of medium thickness, taking up the edges of these structures alternately, is used to construct the "stay-lace" which fills the gap between them with an intercrossing network of threads. Starting below, the stitch ascends the canal in about three insertions of the needle, then descends to its starting-point, where a careful knot is tied. The ascending threads cross the descending ones as nearly as possible at right-angles The stitch must not be tense and must not displace the conjoined tendon. To tie the knot securely without unduly tightening the stay-lace is easy if the assistant grips the threads near the knot with two pairs of smooth forceps

(3) The cord is replaced, the external oblique sutured with three or four interrupted stitches, and the external ring suitably reduced in size.

(4) The external oblique is swept clean by gauze dissection and is darned over the whole extent of the canal by a long thread passing in and out of it and alternately upwards and downwards, but always in the direction of its intercolumnar fibres. The darn provides a new and strong set of intercolumnar fibres for the stretched and thin external oblique. The ends of the darn are cut rather long and tucked away under the skin

The operation is based upon the following considerations:

(1) A silk or linen thread, if aseptic, becomes encysted in a layer of new fibrous tissue which is adherent both to the thread and to its surroundings.

(2) It, however, the thread is under permanent tension it will cut through its attachments to the tissues by a process of pressure atrophy. Hence the stay-lace must be normally slack, though it will become tense during straining efforts.

(3) Both the anterior and the posterior walls of the stretched inguinal canal require strengthening, the former by the darning of the external oblique (a step which Maingot appears to omit), the latter by the stay-lace which fills up the gap below the conjoined tendon.

(4) Normal anatomical structures should not be displaced or put under any abnormal tension. The frequency of recurrence after the Bassini operation is due to the dragging down of the edge of the conjoined tendon to Poupart's ligament. Either the tendon splits and allows a direct hernia to emerge or the stitches may cut through their holds.

Mr. Rodney Maingot's suggestion (May 24, p. 777) that the femoral canal should always be closed by an extension of the stay-lace seems to be an excellent one, and he has shown how the method may be adapted to the treatment of direct hernia. I venture to hope that many other surgeons will try the method.—I am, etc.,

W. SAMPSON HANDLEY.

London, W 1, June 16.

Da Costa's Syndrome

SIR,—You have printed in the *Journal* of May 24 and 31 and June 7 long and interesting articles on Da Costa's syndrome. Dr. Paul Wood is led to the conclusion that this condition is due to central stimulation, and that the stimuli are emotional in nature. The prominence which you have given to these lectures suggests that a very considerable number of cases occur, both in the Army and among civilians, and require appropriate treatment. Clearly such treatment must be directed to the emotional life of the patient; in other words, he requires psychotherapy. If you refer to the summary and conclusions in Dr. Wood's paper of June 7 (p. 845) you will find the following: "Treatment in the Army is shackled by inability to remove the distressing environmental factors which have caused or have aggravated the breakdown; by the difficulty in establishing intimate contact with a patient who did not choose his medical confidant; by the duty of having to serve the State first, the patient second." This could be the text of a long and interesting sermon which I wish Dr. Wood had time to give us.

What therefore happens to these patients? Earlier in the paper he says: "We should endeavour to make the most of material which is not suited to warfare; a man working is an asset; a man broken is a liability." Not long ago we were told in a broadcast that the morale of the nation was so high that the Ministry of Health had closed as unnecessary an

E.M.S. hospital equipped for the treatment of psychoneurosis. This conflict of testimony as to the existence of these cases suggests that, as in the last war, once more, under pressure of hostilities, the State is confusing mental illness with moral turpitude, and we should do well to heed Dr. Wood's advice not to "let our own emotions govern our treatment of these men."

A few years ago an analysis was published of cases of panel patients sent to a referee. This analysis revealed a very high percentage of psychoneuroses masquerading under such titles as anaemia. Possibly some of these sick folk have been benefited by the new valuations afforded by war conditions. A short-sighted view may applaud this, but a longer vision sees the national neurosis of Germany cured by obedience to the machine of war. Dr. Wood emphasizes the importance for success in these cases of the rapport between patient and doctor, and sounds a warning note which should be pressed on the notice of those who are hurrying forward the establishment of a State Medical Service. Will there not be a danger of serving the State first and the patient second? Those of us who are engaged in the work of psychotherapy know that these sufferers can often be restored to social usefulness among their fellows and in the process become less prejudiced and more responsible members of the community.

It is, of course, very difficult for the official machine to test the value of psychotherapy. It can be satisfied that an appendix has, in fact, been removed; but it cannot know what urge in the patient has been satisfied in this way, nor foresee that ere long the patient will resort to the psychotherapist because the operation did not cure him.—I am, etc.,

London, W.1, June 8. GRACE NICOLLE.

SIR,—I should like to congratulate Dr. Paul Wood upon the articles on Da Costa's syndrome published in your issues of May 24 and 31 and June 7. His critical and scientific approach to the subject reaches a standard too rarely seen in work of this nature.

In your leading article (June 7, p. 858) you refer to the title "angina innocens" as being unfortunate in reference to those cases with inframammary pain. I still feel, for the rather small group of patients with (1) really severe pain which (2) radiates down the left arm, and who (3) have other cardiac symptoms, that some distinctive label is necessary which will enable a physician to recognize them and to realize that they are not suffering from angina pectoris—another vague and misleading label.

Labels are made for convenience and should be both brief and free from inaccuracy. The type of pain labelled by me "angina innocens" is a type which exists and for which a distinctive title is needed. Perhaps the writer of your leading article can supply a better one. Failure to recognize this clinical group leads to years of unnecessary apprehension and misdirected treatment of these patients, who in reality are suffering from an innocent condition which often mimics closely anginal pain of an organic type. Unless they are adequately labelled, mistakes in diagnosis will result from their non-recognition.—I am, etc.,

London, W.1, June 9. GEOFFREY BOURNE.

Blast Injury to Lung

SIR,—I was glad to read that the point of my letter of April 26 has been taken by Dr. Osborn (June 7), and that he now endorses the view (emphasized not only in that letter but earlier on[1]) that the term "blast injury" to the lungs should be restricted to those cases in which it can be established that lesions could have been caused by the impact of the blast wave on the body. If in the future he has to differentiate such lesions, he might find it useful to acquaint himself in advance with some fundamental facts relating to blast and explosions, and by so doing discover meaning in what he now finds fantastic and nonsensical. In making a differential diagnosis between blast and some other traumatic agent the greater difficulty is not the recognition of haemorrhagic lesions in the lungs, but determining whether the subject under consideration was in fact exposed to a blast pressure sufficiently high to cause those lesions.—I am, etc.,

Oxford, June 9. S. ZUCKERMAN.

Chronic Sick and Healthy Workers in Bombed Towns

SIR,—The trenchant, moving, and practical plea of Sir Frederick Menzies (June 7, p. 868) for the chronic sick to be removed from public health and assistance institutions, as well as from voluntary hospitals and homes for incurables, to places of comparative safety and comfort outside our large towns, deserves to be insisted upon firmly and *collectively* by the medical profession unless we as doctors repudiate our primary functions of the care and preservation of life and health of the community and the prevention of disease. Do we?

Sir F. Menzies's urgent plea applies equally and more so and for the same reasons to the demand made by British architects, surveyors, doctors, and others qualified technically who advise with scientific and practical authority the provision of communal sanitary shelters affording the fullest possible protection against direct hits from bombs of heavy calibre. If, as is openly said, this war is to be determined eventually by the attempted decimation from the air of British and German civilians, what a ghastly responsibility our Government and the Ministries concerned assume in adhering blindly to their (official) air-raid shelter policy of attempting to "bolster up" the morale of our brave working-class population (on whom the fate and destiny of this country fundamentally depend) by the provision of inadequate and flimsy shelters and "strutted" basements on a haphazard, unscientific, and nationally unorganized "plan." Do not these criticisms also apply to a great extent to the Government policy and plan of evacuation? I cannot believe that the Prime Minister, who approves a "spiritual front," values money more than British lives. Are our Intelligence Departments cognizant of what is being done in Germany (and Austria) to protect civilians against the coming British blitz, and is Hitler likely to spare money to win the war?—I am, etc.,

F. G. BUSHNELL, M.D.,
Woking, June 9. Major R.A.M.C., T.F. (ret.).

SIR,—Sir Frederick Menzies's trenchant letter in your issue of June 7 (p. 868) prompts me to put forward a suggestion. All over the country are established auxiliary convalescent hospitals, equipped and staffed by the British Red Cross Society, under Government auspices and paid for indirectly by Government funds. Country houses of varying types and suitability in localities accessible and inaccessible have been converted to take from forty beds upwards. These are intended for convalescent soldiers, and I will hazard a guess that they are being used at not more than 15% capacity. They are not really suited for convalescent soldiers; although they are well equipped (too well in many cases) and pleasantly situated they lack supervision and discipline. It is impossible to supply from the Army suitable N.C.O.s to carry out necessary disciplinary control and organize physical training and employment, so necessary for convalescent soldiers. These men must be got fit before return to their units, or they have to be hardened up again before they are able to continue strenuous military training or duties. The return of *soft* men to units is a source of irritation and delay in training to C.O.s and company officers.

These auxiliary convalescent hospitals would be ideal for the accommodation of the type of patient to which Sir Frederick refers, and I think that if pressure were brought to bear in the right quarters these institutions could serve a useful purpose to full capacity.—I am, etc.,

June 12. "X."

Vitamin C in the Winter of Wartime

SIR,—I preface these remarks by saying that in my opinion vitamin C is the most necessary of all the vitamins, and that so long as there is an adequate supply of it adults can keep in good health with practically none or very little of the others. I base this opinion on my personal experience, having lived for the best part of seven years in the 'eighties on the Board of Trade dietary for merchant seamen in sailing ships, and later having the medical care of a large mental hospital, where the patients were prone to have ideas about their food and especially green vegetables.

The people who framed the Board of Trade scale some eighty or more years back knew nothing about vitamins as such, yet they devised a diet which kept sailors of those days in a

persistent state of hunger but in good health and able to do the most laborious work under very harassing conditions and at the same time to cost the shipowner the minimum and not encroach on his profits. As an example of efficiency with economy it was a masterpiece.

Except perhaps for some vitamin B, in split yellow peas so hard that I have seen cooks put bits of yellow soap in the soup to soften them, and in biscuits so hard baked that they had to be broken with an iron belaying-pin, I cannot think of any other vitamins in the solid part of the diet. The usual sources of vitamins—milk, eggs, butter, fruit green vegetables, etc.—went with the wind as soon as you dropped the pilot; they just did not exist. Our sea passages were from three to four and a half months, and I never saw anyone ill with scurvy, neither did I ever meet anyone who had. In fact I never saw anyone laid up with any illness; it was no use being ill because there was no doctor and the only medicines were Epsom salts and sulphur dealt out by the steward. The secret of the good health was 1 oz. of lime-juice daily, which had to be taken according to the Act, and anyone who did not like his lime-juice and got sick was "logged" and had his pay stopped.

In my mental hospital experience I found that a good deal of winter ill-health, anaemia, asthenia, oedema of the feet etc.—"scorbutoid" conditions—could be improved by adding vitamin C in the form of pickled red cabbage with some of the meals. The dietary, of course, included boiled cabbage but a considerable part of this, as in any community, I venture to say, goes into the pig-tub, but not so pickled cabbage. Red cabbage pickled has all the attributes necessary for keeping vitamin C intact; it is raw as it is preserved in vinegar, it is acid, and in addition it is appetizing and cheap. If anyone thinks that there is more vitamin in green cabbage then there is no reason why it should not be pickled in the same way.

On reading the report on "Vegetables as Food" (*Journal*, April 26, p. 688) I was surprised and concerned at the enormous tonnage of vegetables produced, with consequent great acreage, labour, cartage, cooking, etc., required for so little real food value, and I cannot help wondering whether it would not be more profitable to rear sheep and grow sheep fodder; this country, like New Zealand, is good for sheep.

I suggest that people who want to have a supply of vitamin C in a palatable form should store pickled cabbage for use in the six to seven months of winter, when green vegetables are scarce and citrus fruits a luxury.—I am, etc.,

H. M. BERNCASTLE

Croydon, June 7.

Sarcoidosis

SIR,—I was glad to see in your issue of May 31 (p. 833) the comments of Major Hugh Garland upon my recent paper on sarcoidosis (April 12, p. 552). In the case quoted there was no evidence of previous local eye trouble such as irido-cyclitis, and several other observers were agreed as to the presence of Adie's syndrome. I was satisfied that the visual field defect was of central origin, and was naturally very interested to hear of the Swedish case where uveo-parotitis was "complicated by a gross cerebral and possibly spinal disorder." My main object in publishing this case was not, however, to claim any constant relationship between sarcoidosis and Adie's syndrome, but rather to illustrate certain speculations as to the nature and stages of infective processes in general. It must readily be admitted that the syndrome of Adie may be the result of more than one special pathological process alone.—I am, etc.,

G. ERIC LEWIS.

Hull, June 3.

Acute Dilatation of the Stomach

SIR,—In their very interesting paper (May 17, p. 751) Mr Maurice Lee and Dr. Edgar Somerville report a case of acute dilatation of the stomach following an operation of partial gastrectomy and discuss the current views of this condition. They could not find an identical case in the literature, but I think the frequently observed symptom of the so-called acute dilatation following operations on the gall-bladder is quite analogous in view of the exciting factors. According to current theories the gastric paresis or paralysis results from impulses through interference with the motor and secretory innervation of the stomach, its mechanism being considered a nervous reflex of the sympathetic-parasympathetic system. Similar troubles, indeed, in a milder and incomplete form, are well known in the symptomatology of the duodenal (juxtapylorie) ulcer, described by Soupault with the name "syndrome pylorique" or, as I have called it, "duodenal symptom complex." The associated obstruction of the duodenum by the root of the mesentery—first described by Rokitansky (1861)—causes, as I think, identical retrograde reactions on gastric motility and secretion.

To the case described by Lee and Somerville I can add an analogous observation which I have published (*Arch. Verdauungskrankh.*, 1928, 43, 410). It refers to a chronic intermittent dilatation of the stomach combined with an intestinal occlusion and complicated by arrosion of an old duodenal ulcer, which caused a fatal bleeding of the gastro-duodenal artery. It is of spontaneous origin, like the majority of the cases belonging to this category which I have studied for years; many of them appeared in the course of wasting diseases. My first researches were made in patients with advanced tuberculosis of the lungs, and this patient also was affected with a chronic bilateral pulmonary tuberculosis. Chronic phthisis with concomitant affection of the bronchial glands plays, too, an important part in a distinct group of peptic ulcers. I have found that the mediastinal portion of the vagus nerve, adherent to and compressed by these glandular callosities, becomes inflamed, and I described (1916) distinct neuritis and post-neuritic atrophy of the fascicles and the medullary sheath of the vagus (see the illustrations in my book *Functional Diseases of the Intestines*, Oxford University Press, 1939 p. 41, ff.).

Knowing this association I could diagnose the condition in the mentioned case during life as a gastroplegia and dilatation of the stomach and a paralytic intestinal occlusion, probably connected with a lesion of the vagus nerve, which has been completely confirmed by the post-mortem. For particulars I must refer to the quoted papers and my report to the second Congrès International de Gastro-entérologie, Paris, 1937. But I lay, too, stress upon the fact that the whole condition is neurogenic, a consequence of a kind of paralysis caused in a blocking of the gastro-intestinal regulation. Gastric dilatation in the forefront of clinical symptoms and the constriction of the duodenum are co-ordinated affections, both provoked by the paralytic intestinal occlusion which starts with the slipping down of the convolutions of the small intestine into the true pelvis. The raising of the pelvic region (Trendelenburg) first recommended by Schnitzler is a very effective part of the treatment, but it must be completed by other means.—I am etc.,

GUSTAV SINGER, M.D.,
Emeritus Professor, Vienna University.

Sanderstead, May 26.

Ether Convulsions

SIR,—I had the fortune to see a number of striking cases of this condition a good many years ago, when I was working for a few months in an area where heated ether was the routine anaesthetic. In all the years that have since passed I have seen but one case, in which the circumstances were so unusual that I must mention them in some detail. The patient, a woman approaching 70, was under light anaesthesia with gas and oxygen combined with local (novocain). No ether at all had been used intentionally, though it is probable that a small amount of ether was lying in the rather complicated apparatus which was used. Despite these unusual circumstances, I had no difficulty in recognizing the nature of the case, which was unmistakable.

It is to this unmistakable character of the convulsions, as I have seen them, that I am now writing to draw attention. I think I have read most of the annotations on the subject, and I do not think I have seen described what I would regard as the really typical feature. It is that the convulsion is essentially expiratory. A prolonged and violent clonic convulsion is intermittently and momentarily interrupted by a short inspiratory gasp, during which the convulsion ceases. From the cases I have seen I should regard this as completely typical, but I am sure it has not been generally described. Unless they conform to this type, convulsions under anaesthesia should not be spoken of as "ether convulsions."

The other and more generally recognized characteristics of prolonged deep anaesthesia and hyperpyrexia were also manifest in the cases I saw. One fatal case reached a temperature of 110° F. I cannot, however, subscribe to the

emphatic statement made in Mr. Dickson Wright's letter in your issue of August 31, 1940 (p. 299), in which he says that the cause must be sought not in the anaesthetic but in the "feverish, atropinized, mackintosh-covered patient." One cannot but be influenced by one's own experience, and in my own case there can be no argument about the direction in which that points. It points to the conclusion that heated ether is the responsible agent. I am not prepared to maintain that this is the whole of the matter, but I am convinced that it is the heart of the matter.—I am, etc.,

Liverpool, June 9. CHARLES WELLS.

Carriers of Tuberculosis

SIR,—The object of Dr. James Maxwell's paper (May 3, p 665), to stimulate the search for the human sources of tuberculosis infection and to emphasize that there are a number of people who cough up tubercle bacilli without any adequate stethoscopic and radiographic findings, deserves full consent. But the conception of "tuberculosis carriers" must be firmly contradicted. It implies the acceptance that the tubercle bacillus may play the part of a saprophytic parasite in the human organism, and this hypothesis, far from having the shadow of a proof, appears to be most dangerous. Rarely saprophytic acid-fast bacilli have happened to be found in bronchiectatic sputum and in the discharge of lung abscesses, but they could not be acknowledged as tubercle bacilli when they were cultured. We are bound up with the principle that the presence of genuine tubercle bacilli in the sputum means a destructive tuberculous process, even a minute one, in the lung tissue, in the mucous membrane of the bronchial tract, or in a lymph nodule. If thorough and repeated examinations fail to reveal the spreading focus it is owing to our diagnostic inefficiency and to the benign and sluggish features of the tuberculous lesions. Patients like those reported by Dr. Maxwell (Cases 2, 3, 4) are not to be considered as T.B. carriers whose positive expectoration causes only a *social* interest; they themselves are in danger, though perhaps they will escape the danger for many years or for good; they are ill and should be subject to never-ceasing attempts to discover the obscure sources of their infectivity. Positive sputum is, according to our recognition, the sure sign of active tuberculosis, although the concerned lesion may be hidden, stationary, "arrested"—that is, at present confined and not prone to advance, but the threat of advance is existing. The term "activity" ought to be used for the definite prospect, not for a momentary stage, and activity requires continuous observation. There is no way of "sterilizing the respiratory tract" but the attempt to cure the tuberculous lesion.

As it is proved by extensive investigation that the infectibility of a tuberculous patient depends on the quantity of the ejected bacilli—that is, on the amount of cough and sputum—the public danger arising from cases which occasionally bring up a small number of bacilli is much less than that from cases simulating a chronic "catarrh." The outstanding task of prevention is therefore to teach doctors, nurses, and laymen that every protracted or relapsing bronchitis and tracheitis requires radiographic and sputum supervision, and that the occurrence of general good health, including normal temperature, undiminished body weight, and even perfect sportive fitness, does not rule out at all the presence of active tuberculosis.—I am, etc.,

High Carley Sanatorium, near Ulverston, June 3. E. FRAENKEL, M.D.

Control of Tuberculosis

SIR,—Dr. G. E. Johnston's contribution on the control of tuberculosis (June 7, p. 868) must have aroused wide attention. He has put forward a number of interesting suggestions which can undoubtedly form the basis of discussion on this all-important question. Certain fundamental principles, however, must first of all be accepted.

The whole problem of the control of tuberculosis is in essence a *social and national question* conditioned largely by overcrowding, malnutrition, and bad housing, and the solution must have a national and not a local form. Thus any scheme which is to be embarked upon must, for its success, be assured Governmental financial support and in addition national planning.

Dr. Johnston's suggestion that the country be divided into regions is certainly the logical approach. Such a regional scheme would no doubt have as its basis the size and density of the local population and not be dependent on any of the existing artificial county boundaries. Each region would have its quota of sanatorium beds and in addition a "settlement scheme on Papworth principles."

The medical control of the suggested scheme could be conducted by a joint medical tuberculosis committee presided over by the chief regional tuberculosis officer, with its membership drawn from the local tuberculosis officers and medical superintendents of both the sanatoria and the associated "settlement." It is just such a committee which could allocate the available beds to: (*a*) cases which could reasonably be expected to respond to some form of collapse therapy; or (*b*) patients who would profit by a brief period of sanatorium regime for its purely educational value in the conduct of their future private lives. Furthermore, this joint medical tuberculosis committee would have the unique opportunity of collating the statistical data of all mass surveys and medical and surgical investigations conducted throughout the region. It is more than probable that, in pursuing such a course, the quality of the work of the more backward and unprogressive institutions would be raised to a higher level. Finally, such a regional medical committee could very satisfactorily combine with the general practitioners of the area in the domiciliary treatment of the chronic and incurable cases for whom sanatorium therapy is redundant.—I am, etc.,

Middleton Sanatorium, Yorks, June 7. BERTRAM MANN.

Injury and Internal Disease

SIR,—The clearly written paper by Dr. G. F. Walker (May 3, p 659), with its painstakingly collected case records, deserves—and I trust it will—to go down in the medical literature as a standard work of reference for students of this special question. It is therefore essential that it should be as complete as possible.

May I add one very important item which unfortunately has been entirely overlooked: rheumatism. There is practically no other internal disease which would in the everyday life so frequently and so clearly show the intimate relationship with injury like the varied forms of rheumatism do. Fascinated by the striking evidence given by so many of my own cases already many years ago I felt induced to try and give a possible explanation of this, beyond any doubt, observed fact. Some new—in those days anyhow—findings of blood serology and immunity (*Immunitätslehre*) have supplied a useful basis. In an elaborate paper on "Trauma and Rheumatismus" (in the early 'twenties in the *Wien. klin. Wschr.*) I have laid down some principles which proved to be a very useful working hypothesis ever since. A short reference may be found in another paper of mine on "The Balneological Treatment of Post-traumatic Rheumatic Exudates" (*Arch. med. Hydrol.*, Aug., 1925).

By now injury is generally considered as a causative factor *par excellence* of rheumatism, corresponding one way or the other with the triple classical criterion (*a*, *b*, *c*) of Dr. Walker's paper.—I am, etc.,

L. SCHMIDT, M.D. (Prague).

Buckminster Hall, Grantham, May 24.

Physical Medicine and Orthopaedics

SIR,—Your annotation on physical medicine and orthopaedics (April 26, p. 633) appears to have upset certain orthopaedic surgeons, and a reply is called for to the letter of Prof. Harry Platt and of the president and secretary of the B.O.A. and the chairman and members of the Standing Committee on Fractures (May 24, p. 791). As a mere physiotherapist it is with considerable temerity that I venture to cross swords with this distinguished group of orthopaedic professors and surgeons.

First let me say that I entirely agree with them that the title of "orthopaedic physician" would be a misnomer, for the very good reason that the physiotherapist is called upon to treat every type of case both surgical and medical. At some stage or other practically every type of hospital case needs and benefits by physiotherapy, and though we treat large numbers of orthopaedic patients, we treat still larger numbers of general surgical and medical cases. In my opinion a mistake has been made in so closely identifying orthopaedic surgery and physiotherapy. Having agreed thus far with the orthopaedic surgeons I must now take up arms in defence of the physiotherapist.

Prof. Platt states that "the orthopaedic surgeon prescribes [physical treatment] in detail . . . and controls such treatment throughout. The writer of your annotation must realize that there will be no withdrawal from "the position." I am afraid that Prof Platt must regard the physiotherapist as an unnecessary form of human life. Now it is the duty of the physiotherapist to see that the instructions of the surgeon or physician are faithfully carried out. Unfortunately many medical men have the misfortune not to possess Prof. Platt's knowledge of physical medicine and numbers of patients are still referred to our departments with no further instructions than the two words "Please treat." Many eminent surgeons still fall into the error of asking for a "muscle test" to be done within twenty-four hours of a suspected nerve injury, while others through lack of knowledge prescribe various forms of electrotherapy, which, if carried out, would be definitely harmful to the patient. It is, therefore, most necessary to have a physiotherapist in charge, who can suggest more suitable forms of treatment to the physician or surgeon. The two letters already referred to almost suggest a definite hostility on the part of the orthopaedic surgeons concerned towards physiotherapists, though for my part I have always experienced complete collaboration from every orthopaedic surgeon with whom I have worked.

The letter signed by the president and secretary of the British Orthopaedic Association and others states: "The blue lights and red lights, the long waves and the short waves, which loomed so prominently in the past, will be relegated to their proper place." This is a particularly unfortunate statement for a fracture committee to have made, and one is forced to conclude that they have been too busy to keep themselves up to date as regards the possibilities of modern electrotherapeutics. In short-wave diathermy, correctly given, we have a most valuable therapeutic agent to assist the orthopaedic surgeon in the treatment of compound fractures and trauma of soft tissues, of which types of case there are now unfortunately such large numbers. The treatment can be given through plaster, and both speeds up the resolution of sepsis and hastens union. Further, it has the power of relieving pain. Unfortunately the Fracture Committee does not appear to have investigated this form of treatment, and would consign it to the scrapheap. The red and blue lights to which they refer have disappeared for many years, though one may venture to suggest that if the exhibition of a coloured light will produce a cure, it is just as legitimate medicine as the bottle of coloured fluid prescribed by the physician. Both are examples of autosuggestion in its most elementary form.

Undoubtedly in the past various methods of physical medicine have been employed which were quite unworthy even of the adjective "empirical." But the physiotherapists were not alone to blame. Their departments were used as dumping grounds for unwanted patients by the physicians and surgeons, who not only supplied unsuitable material but prescribed unsuitable forms of treatment. Physical medicine is now past the experimental stage and on sure foundations. Thanks very largely to the orthopaedic surgeons the science of massage, exercise, re-education, and rehabilitation is now completely rationalized. On the electrotherapeutic side the value of surging faradism has never been in dispute; short-wave diathermy, correctly applied, is of the utmost value in all septic and inflammatory conditions; local ultra-violet light promotes the more rapid resolution and healing of various skin lesions; while the slow galvanic current, used with the correct technique and in properly chosen cases, has its place in the treatment of peripheral nerve lesions. The physiotherapist of to-day has (or should have) a complete orthopaedic training and keep abreast of modern medicine and surgery. He is thus in a position to give physical treatment to every type of case and has valuable wares to offer, and in intelligent and amicable collaboration with his colleagues can give invaluable services.

This letter is not an attack on the orthopaedic surgeons, for whom and for whose work I have nothing but admiration, but an attempt to justify the physiotherapist. The art of orthopaedic surgery has now attained to so many ramifications that the orthopaedic surgeon's time is fully employed in consulting and operating. Once he has gained confidence in his physiotherapist he will be pleased to leave the direction of physical medicine in his hands.—I am, etc.,

E. J. CRISP.

London, W.1, May 31.

Medical Certificates

SIR,—All whose duty it is to issue certificates of unfitness for work must frequently recognize that a patient, while unfit for his own employment, is yet perfectly able to do other work. Unless the patient's employer is able and willing to provide him with a light job—and often this is not so—the man remains off work. This represents a wastage of man-power that the country can ill afford. Perhaps I may quote some recent examples from my own hospital.

An A.F.S. man had an operation for hernia a month previously. "There is no light work in the Fire Brigade"—this though they employ women. Am I to keep him off work for two more months?

An engineer officer in the Merchant Navy had a bomb fragment removed from the region of his shoulder-joint. He is very slow to regain abduction of his arm. He obviously cannot get back to sea but meanwhile is anxious to employ his talents in an aircraft factory. He had fixed up to do this, but his present employers pointed out that the present regulations would make it difficult for him to get back to his old job if he later became fit to go to sea again, so he still kicks his heels all day.

An ambulance driver fractured his scaphoid, and, as it happened remained in plaster for eight months. During this time his employers were unwilling that he should drive an ambulance, and did not provide him with other work. Though willing to be a fire-spotter, he was not allowed to retain the post, as such, which he obtained.

Finally the wearing of a bandage immediately disqualifies a policeman for duty, however minor the lesion.

In order to prevent this wastage of man-power, I suggest that there should be health grades in civil as well as military life, and that it should be possible to downgrade a man temporarily; that while fit for work other than his own he should be registered as such at the employment exchange, and his services utilized as occasion offered. Surely in this way we could at least obtain fire-spotters for every important building in the country.—I am, etc.,

R. L. BENISON.

London, N.6, June 7.

The Psychology of Quislingism

SIR,—In your annotation with this title (May 31, p. 823) you refer to a study I published on the unconscious sources of the phenomena. In your comment you write: ". . . However hypothetical these speculations may be, etc. . . ." I should like to say that my conclusions were not intended to be put forward as speculations, but, as was stated in the study, as results obtained from the close investigation of actual material—material of a kind which is, unfortunately, still available. It was further pointed out that, if the conclusions are confirmed by further investigations, they have an important practical bearing on the political problem of combating Quislingism, it being presumed that this is still a social desideratum.—I am, etc.,

ERNEST JONES.

London, N.W.1, June 12.

A meeting of the Joint Tuberculosis Council was held in London at the end of May, when ten committees with their conveners to deal with specific subjects were appointed. Among the questions entrusted to the committees were milk, nursing, postgraduate instruction, tuberculosis in wartime, the major surgical treatment of pulmonary tuberculosis, and the institutional treatment of children. A report from the Care and Employment Committee was considered at some length. Several members suggested that too much importance had been laid on the value of voluntary care committees, and that as time went on the value of such committees would decrease. It was also suggested that more stress should be laid on the employment of patients in sanatoriums. Ultimately the report was referred back to the committee, and a special meeting of the Council is to be called to consider the final draft, to which it is hoped to give wide publicity. A questionary was recently sent out to more than 100 tuberculosis institutions on the shortage of nursing and domestic staff. Some 70% of the institutions proved to be short of staff, and the consequences are likely to be serious unless something is done to alleviate the situation. It was agreed to summarize the figures with a view to a final report which will be forwarded to the Ministry of Health.

Obituary

HENRY WILLIAMS JEANS, M.B.

The City of Portsmouth has suffered a great loss by the sudden death of one of its most respected general practitioners, Dr. H. W. Jeans.

Son of a naval officer, he graduated M.B., B.Ch. of the University of Aberdeen in 1904. He then went to Portsmouth, obtaining the position of senior house-surgeon at the Royal Portsmouth Hospital, and afterwards becoming honorary radiologist. This specialty he did not continue with, but went into general practice, where he soon became deservedly popular both with his patients and with professional colleagues. In the war of 1914-18 Dr. Jeans served in the R.A.M.C. at home and in France. Returning to Portsmouth he resumed his practice, and took a leading part in the activities of the B.M.A., serving on the Executive Committee for many years, and becoming vice-chairman of the Portsmouth Division in 1929-30, chairman 1930-1, and on five occasions representing the Division at Annual Meetings of the Association. For many years he was a member of the Portsmouth Panel Committee, and a medical representative on the Insurance Committee. During the present war he was a member of the Local Medical War Committee.

Dr. Jeans always had the welfare of his fellow-practitioners very much at heart, and many of his colleagues have had reason to be thankful for his help and advice in solving and smoothing over the many problems and difficulties connected with medical practice. His strong personality and geniality will be much missed. He leaves a widow and a son, Major H. Jeans.

R. PERCY SMITH, M.D., F.R.C.P.

Dr. Robert Percy Smith died at Durley, Southampton, on June 4 at the age of 87. He was originally intended for a business career, but soon gave it up in favour of the profession of his choice. He was a brilliant student at St. Thomas's Hospital, winning the gold medals in medicine and obstetric medicine at the London M.B. and honours in forensic medicine. He obtained the M.D. in 1881, and nine years later was admitted to the Fellowship of the Royal College of Physicians.

After the ordinary posts at St. Thomas's Hospital he was appointed resident assistant physician for a couple of years. Shortly afterwards there was a vacancy on the staff of Bethlem Royal Hospital, and he became assistant to Dr. (later Sir George) Savage, who retired two years later and Smith was fortunate enough to be elected medical superintendent at the early age of 34. In some ways this was perhaps somewhat unfortunate because it directed Smith's interests into the administrative rather than the scientific aspects of psychiatry. Nevertheless, during the ten years of his superintendency he obtained an international reputation and was awarded honorary membership of the Società Freniatrica Italiana and the Associated Society of Medical Psychology of Paris. He was lecturer on mental diseases at Charing Cross Hospital and for longer at St. Thomas's Hospital. Dr. Percy Smith was successful as a consulting physician in Queen Anne Street from 1898 onwards, and he had an extensive practice. In 1904 he was president of the Medico-Psychological Association of Great Britain and Ireland, in 1916-17 of the Psychiatrical and Neurological Sections of the Royal Society of Medicine, and for a good many years he was the Editor of *Brain*. He was at various times examiner in mental diseases to the Universities of London and Leeds and also of the Conjoint Board. Of the British Medical Association Dr. Percy Smith was a member for fifty-four years, and he served sa honorary secretary of the Section of Psychology at the Annual Meeting of 1889 at Leeds. He was president of the same Section in 1900 at Ipswich.

"R. P." (as we used to call him) was not a prolific writer, but he wrote some of the articles in the *Practitioner's Encyclopedia of Medicine and Surgery* and occasionally in the journals. The one book of which he was part author, *The Insane and the Law*, however, was and is a most valuable work, and was, so far as we are aware, the first of its kind to deal with the whole subject in a systematic manner. It was written in collaboration with two barristers—namely, Mr. (now the Hon. Mr. Justice) J. A. Hawke and the late George Pitt-Lewis, K.C.

The most outstanding feature of "R. P.'s" character was his punctilious devotion to duty. At Bethlem he saw and spoke with every patient every day and, what is more, he made all other members of his staff go round with him and do the same. He kept copious and careful shorthand notes of all his patients both at Bethlem and in private. Moreover, he was regular in his attendance at the hospital chapel. When he resigned in order to take up consulting practice he was made a governor of the hospital, and he was regular in his attendance at the Court of Governors and weekly committee meetings even after the hospital was moved to Beckenham and right up to a couple of years ago.

Percy Smith was much in request as a witness in legal cases but it aroused his indignation when the Court stopped him from fulfilling his obligation to tell the truth, the whole truth and nothing but the truth. He was good at outdoor games, but he never allowed them to dominate his life. He played golf at Northwood regularly and continued to do so until last year. Never a publicist, Percy Smith was no seeker after fame or honours, but was himself the soul of honour, probity, integrity and candour, who never deviated an inch from that straight line of conduct laid down by his brethren for our pursuit.

W. H. B. S.

By the death of Dr. JAMES HENRY ALLAN of Thingwall Road at the advanced age of 84, Liverpool has recently lost one of its well-known and oldest medical practitioners. He was a native of Stockton-on-Tees, was educated at Stockton Grammar School, and early in his career gained the Jacob Bell Senior Scholarship at King's College, London. After qualifying as pharmaceutical chemist he became dispenser to the Children's Infirmary and Royal Infirmary, Liverpool, where he taught pharmacy and materia medica to several generations of medical students. Later, as a chemist, he established numerous pharmacies in Liverpool, and subsequently, at the age of 50, qualified L.R.C.P.&S.Ed., L.F.P.S.G., and practised medicine in Everton for many years until his retirement from the profession a few years ago. Dr. Allan was a member of the B.M.A. for many years. He is survived by his two sons, Dr. John H. Allan and Dr. James S. Allan. Another son, Captain Noel J. Allan, R.A.M.C., was killed in Mesopotamia in 1918.

The following appreciation, by E. Le C. L., supplements the obituary notice of Mr. WILLIAM FREDERICK BROOK, F.R.C.S., senior consulting surgeon to the Swansea General and Eye Hospital, consulting surgeon to the Carmarthen Infirmary and to the Port Talbot and District Hospital (June 14, p. 911). Gifted with rare surgical insight, he was a very sound, most careful, and when need arose a brilliant, surgeon (as the present writer can well testify, having administered for him some 2,000 anaesthetics) and at a comparatively early age established himself as the leading surgical consultant in West South Wales. A vigorous, alert personality, a loyal, generous colleague, a true friend, he inspired in all who knew him well feelings far deeper than mere affection. Among disabled ex-Service men, past, present, and future, Brook's name should long be treasured in grateful remembrance, for he was the founder of the British Legion Medical Advisory Committees which supply information and advice to the Ministry of Pensions and have been of untold benefit to thousands of disabled men. For some years he was hon. treasurer of the Swansea Branch and president of the West Glamorgan and Carmarthenshire County Committee of the Legion. The first of these advisory committees was that at Swansea, and while receiving enthusiastic support from some of his colleagues on the hospital staff, Brook was the originator of the whole scheme. Mrs. Brook survives him, also his two children, Acting Group Captain Arthur Brook, R.A.F., and Miss Barbara Brook, local hon. secretary of the R.S.P.C.A.

The following well-known medical men have died abroad: Dr. ALBERT BENJAMIN MCCREARY, State Health Officer for the State of Florida and Commander of the Cuban Order of Carlos Finlay, aged 45; Prof. A. C. PEREIRA, of the chair of toxicology in the University of Lisbon, aged 73; and Dr. CHARLES JOSEPH WHALEN, editor of the *Illinois State Medical Journal*, aged 72.

The Services

NAVAL AWARDS

Temporary Surgeon Lieut.-Commander William Milne Wilson, R.N.V.R. (H.M.S. *Carnarvon Castle*) has been mentioned in dispatches.

CASUALTIES IN THE MEDICAL SERVICES

Royal Navy

Surgeon Commander HENRY HURST, R.N., who is reported as "Missing, Believed Killed" in H.M.S. *Hood*, received his medical training in Dublin, at the school of the Royal College of Surgeons in Ireland, taking the L.R.C.P.&S.I. in 1917. He served in the war of 1914-18, and reached the rank of surgeon commander in 1930. He leaves a widow. He had been a member of the British Medical Association since 1928.

Temporary Surgeon Lieut. HUGH MARKS, R.N.V.R., the only son of the late Mr. Hugh Marks and Mrs. E. A. Marks of Randalstown, lost his life shortly after embarking on his first ship. He was educated at Portora Royal School, Enniskillen, and Queen's College, Belfast, qualifying L.R.C.P.&S.I. in 1939. He held the post of resident medical officer at Kilmeminster Hospital before entering the R.N.V.R. He was a member of the British Medical Association.

Missing

Surgeon Lieut.-Commander Claude Denis Delacour de Labilliere, R.N.

Royal Army Medical Corps

Major RICHARD FOWLER WARD is included as "Killed" in an Army Council casualty list published on June 11. He received his medical education at the London Hospital and qualified M.R.C.S., L.R.C.P. in 1926. He also took the M.B., B.S. degrees of the University of London in 1927 and obtained the F.R.C.S.Ed. in 1930. He had held the posts of clinical assistant to out-patients at the London Hospital, casualty officer and house-surgeon and later honorary anaesthetist, at the East Suffolk and Ipswich Hospital, house-surgeon at the Derbyshire Royal Infirmary, and clinical assistant at St. Peter's Hospital, London. Before the war he was honorary surgeon in charge of the urogenital department of the East Suffolk and Ipswich Hospital.

Lieut. THOMAS WILLIAM GREATOREX died in May from wounds received on active service in the Middle East. He was 26 years of age and was the only son of Dr. R. W. Greatorex of Halifax. He qualified M.R.C.S., L.R.C.P. in 1940.

Royal Air Force

Squadron Leader HARRY WINTON DRYERRE, R.A.F.V.R., died on June 9 in a Royal Air Force hospital in England from the result of a motor accident. He was the son of Prof. Henry Dryerre of the chair of physiology, Royal (Dick) Veterinary College, and, like his father, was a student of the University of Edinburgh, where he graduated M.B., Ch.B. in 1934. He also obtained the M.R.C.P.Ed. in 1936 and became a Fellow in 1939. He won the Crichton Research Scholarship in 1937-8. After and the Houldsworth Research Scholarship in 1937. holding house appointments at Edinburgh Royal Infirmary he became assistant pathologist to the University of Edinburgh. Before the war he was pathologist to the Edinburgh Municipal Hospitals and clinical tutor at Edinburgh Royal Infirmary. He joined the British Medical Association in 1934 and was also a member of the Royal Society of Medicine, the Pathological Club of Edinburgh, and the Medico-Chirurgical Society of Edinburgh. He contributed two articles to the *British Medical Journal* in 1939, one on the effect of desoxycorticosterone acetate and cortin on salt elimination in Addison's disease and the other, jointly with Mr. W. Hunter, on duodenal ulceration in the newborn.

Flying Officer JAMES FERGUSON HARPER, R.A.F.V.R., who was killed in a flying accident last August at the age of 29, was the younger son of the late Mr. A. R. Harper, town clerk of Renfrew, and Mrs. Margaret Harper, and was educated at the University of Glasgow, where he graduated M.B., Ch.B. in 1935. After holding resident hospital appointments in Glasgow he went as ship surgeon on a liner to the West Indies and a year later made a voyage round the world. On his return he acted as an assistant in a general practice in Perthshire for about two years. In January, 1940, he joined the R.A.F.V.R., and as he believed his services as a doctor might on occasion be more valuable if he could pilot an aeroplane he spent much of his spare time in learning to fly, and it was while practising that he lost his life.

Flying Officer JOHN ANTHONY ATWILL lost his life by enemy action in April. He was the only son of Mr. and Mrs. Lionel Atwill, and received his medical education at St. Bartholomew's Hospital, qualifying M.R.C.S., L.R.C.P. in 1940. He was 26 years of age.

DEATHS IN THE SERVICES

Fleet Surgeon JOHNSTON HAMILTON ACHESON, R.N. (ret.), died at Torquay on May 13, aged 76. He was educated at the University of Edinburgh, where he graduated M.B., C.M. in 1887; he also took the D.P.H. of the University of Cambridge in 1910. He reached the rank of fleet surgeon in 1904. He had seen a lot of service in Africa, first with the naval brigade which landed to put down King Koko, the chief-tain, on the River Niger, in 1895 (general African service medal with clasp) and later with the naval brigade landed at Mombasa for the punishment of a rebellious chief, also in 1895, when he was mentioned in dispatches. He had been a member of the British Medical Association for fifty-three years.

Universities and Colleges

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council held on June 13 the resignation of Dr. Dorothy Lewis of the post of assistant in bacteriology was accepted with regret, and Dr. Lewis was thanked for her services to the University.

The late Colonel Sir Charles Clifford, K.B.E., LL.D., by his will left a share of his residuary estate to the University of Sheffield. Since the death of Lady Clifford on May 1, the residuary estate falls to be divided between the beneficiaries. It is expected that the university will receive upwards of £50,000 after duties have been paid.

UNIVERSITY OF WALES

The Welsh National School of Medicine

The following candidates have satisfied the examiners at the examination indicated:

M.B., B.Ch.—*Medicine*: N. E. France, Vera Harris, Margaret W. Hughes, D. F. V. Johnston, W. M. Jones, Gwenllian M. Lewis, J. Lewis Monica Parry-Morton, D. K. W. Picken, J. B. Randell, H. I. Rees, Nest G. Richards, Barbara C. Roberts, Erica M. G. H. Roberts, J. H. Stranger, E. R. Treasure, Glenys J. Wade, J. Williams, O. Williams, G. A. Wright. *Pathology and Bacteriology*: N. A. Cohen, R. C. Cummin, D. W. Davies, Margaret Davies, S. C. Dymond, Elizabeth M. E. Evans, R. G. Evans, Margaret A. Griffiths, A. J. L. Haley, F. J. Hedden, R. A. N. Hitchens, H. J. Houghton, Lilian Howell, J. I. Hughes, Dorothy M. Hyde, Sarah J. Jenkins, A. M. Jones, G. N. Jones, Menna Jones, I. Mazin, Margaret E. Milter, S. Morgan, Ivy M. Morgans, Celia M. Rapport, Dilys M. Rees, J. F. Rees, Dorothy Roberts, T. H. L. Rosser, Edna E. Saunders, H. F. Sugden, Freda Thomas, Mary E. Tighe, A. K. Toufeeq, D. G. H. Tutton, Marjone Whitney, G. R. Williams, S. E. Williams.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary meeting of the Council was held on June 12, with the President, Sir Hugh Lett, in the chair.

Examiners were elected for the ensuing year.

A cordial vote of thanks was given to the American Ambulance for their assistance in conveying specimens from the College to various parts of the country.

The subject for the Jacksonian Prize for 1942 is "The Methods and Results of Treatment in Cases of Paralysis of the Bladder following Spinal Injury."

It was reported that the Blane Medal for 1941 has been awarded to Surgeon Commander James Callaghan Souter, R.N.

The election of Sir Arthur Smith Woodward and Prof. Matthew J. Stewart as Trustees of the Hunterian Collection was reported to the Council.

Diplomas

Diplomas of Fellowship were granted to the following thirty-five candidates:

C. J. Gordon, J. I. C. Mason, W. M. Beattie, E. G. Murphy, K. E. Bond, J. C. Adams, W. J. C. Crisp, J. Swift Joly, C. P. Nicholas, A. W. Stewart, M. Albert, R. Bloom, G. H. Wooler, L. A. Ives, O. T. Mansfield, D. V. Morse, J. A. C. Edwards, J. D. Wade, B. E. C. Stanley, H. M. Goldberg, E. H. Travers, A. J. Drew, Katharine I. Liebert, L. J. Temple, H. L. Catchlove, R. S. Monro, H. E. H. Denham, T. L. J. Barry, R. V. Blaubaum, J. Henderson, N. S. Martin, T. O'Neill, F. P. Raper, A. J. Slessor, Eileen M. Whapham.

A Diploma of Membership was granted to George Kenneth Tutton, of Manchester University.

Diplomas in Anaesthetics were granted, jointly with the Royal College of Physicians of London, to the following twenty-two candidates:

Sheila M. Anderson, S. K. Bakhshi, Helen E. M. Barnes, J. T. Barr, J. D. Burrows, Margaret M. J. Conway, D. M. Dunn, Jean L. Edwards, M. Garden, W. W. Gilford, H. C. R. Gunter, C. F. Hawkins, F. Hoenigsberger, J. Ives, H. R. Marrett, G. F. Panton, C. Reid, K. Roberts, Margaret J. Rowley, H. J. A. Simmons, J. M. Smith, K. B. Thomas.

Medical Notes in Parliament

Home Guard Medical Officers

On June 11 Mr. GROVES asked whether senior medical officers were to be appointed for the larger Home Guard commands, what rank they would have, and when it would be possible for them to commence their duties. Captain MARGESSON replied that in addition to battalion medical officers arrangements would shortly be made for the appointment of zone medical advisers with the rank of lieut.-colonel wherever such an appointment was considered essential.

Captain Margesson also told Mr. Groves that the appointment of a medical officer at the War Office to make personal contact with senior medical officers of the Home Guard was not necessary The Director-General, Home Guard, was in close touch with the Director-General, Army Medical Services, on all medical questions affecting the Home Guard. No difficulty had been experienced in obtaining first-hand information where necessary of conditions in the Forces.

Milk Rationing

Major LLOYD GEORGE said on June 11 that it would be impossible to revise the milk rationing scheme so as to provide one pint of milk for all children under 16 years of age and a half-pint for all adults. The quantity required to meet the suggested ration, assuming that the whole of the ration was taken up, would be 50% in excess of the total milk production of the country at the period of the year when the milk output was at its lowest figure.

On June 12 Major Lloyd George stated that the payment of a fee for a medical certificate to obtain extra milk was not required under any regulations issued by the Ministry of Food.

Medical Services in a Civil Defence Ministry

In the debate on civil defence in the House of Commons on June 11 and 12 Dr. HADEN GUEST pointed out that stretcher parties, ambulances, and hospital organizations were administered by two Departments. He held that they ought to be joined.

Mr. HERBERT MORRISON did not accept the contention that all civil defence functions should be concentrated in one Ministry of Civil Defence. Big-scale movements of the population involved nearly every department of public health administration, and a Ministry of Civil Defence, as evacuation authority, would have to take functions from the Ministry of Health and the Board of Education. Was Mr. Brown to retain such hospitals or parts of hospitals as were required for illnesses which might happen in peace while the Minister of Civil Defence took hospitals for illnesses or injury due to the enemy? How could they cut hospitals or medical administration into two? Dr. GUEST remarked that hospital administration was already cut in two. The Emergency Medical Service, which included most of the hospitals, provided accommodation for the soldier and could also provide it for those who were injured in air raids. The Emergency Medical Service hospitals were run by the Ministry of Health and had an account with the War Department for soldiers who were taken in. He suggested that people injured by air attacks should likewise be taken in under a national scheme run by the Ministry.

Mr. MORRISON said he would concentrate all doctors under one Department so far as possible. The administration of hospitals should be under one Department. The question was, What was the proper Department? He thought it was Mr. Brown's. The Ministry of Health had experience of hospital administration and it was right that they should do it. If all the health and medical services which related to civil defence were taken from Mr. Brown and if the school medical services were taken from Mr. Ramsbotham and were handed to the Minister of Home Security the Government would be forced to surrender and revert to the old way. When the Air Raid Precautions Act, 1937, was passed, there was set up at the Home Office an A.R.P. Department in which was a hospital department and a medical department with a limited number of doctors. It became clear that the unfortunate officers of the Home Office were out of their depth in hospital administration. Sir John Anderson in 1938 made changes in that. Mr. Morrison added that although he argued strongly against the creation of one Ministry of Civil Defence, the Government did not close its mind on the matter. They must think about the shortage of expert man-power before making radical changes.

Instruction in Treatment of Gas Casualties

On June 12 Sir FRANCIS FREMANTLE inquired whether the Ministry of Health entered into consultation with the Council of the British Medical Association on the instruction of the medical profession in the treatment of gas casualties. Mr. BROWN replied that lectures to general practitioners on the treatment of gas casualties were being arranged throughout the country, through the co-operation of the British Medical Association. They would be given by medical teachers with practical experience in this special subject, and would be open to all general practitioners. An authoritative memorandum on the subject recently appeared in the medical press. A copy would shortly be sent direct to every registered practitioner in this country other than those serving with H.M. Forces.

Registration of Alien Doctors

Sir FRANCIS FREMANTLE asked on June 12 what number of friendly foreign doctors were now on the British *Medical Register*, and whether the promised number of over 100 were added each week. Mr. BROWN said the number of doctors, apart from those commissioned in the British or Allied Forces, registered as foreign practitioners under the Medical Register (Temporary Registration) Order, 1941, was 289. All were now in medical employment or had such employment which they were free to take up. The Central Medical War Committee had sent forward to the Security Departments the papers of all doctors who had furnished the required particulars, averaging eighty a week in the last three weeks. The subject was not without difficulties, but there had been considerable improvement, and the Home Secretary desired to make that improvement as great as possible.

Chronic Sick in Bombed Towns

On June 17, Sir ERNEST GRAHAM-LITTLE asked the Minister of Health how many chronic sick and bedridden patients were still housed in public health and public assistance institutions, in voluntary hospitals, and homes for incurables in London and other large cities which had suffered intensive bombing, and what effort had been made to remove such patients from dangerous areas. Mr. E. BROWN said he could not give this total without elaborate and detailed inquiry from a large number of different authorities. The desirability of removing as many as possible of the chronic sick from the vulnerable areas was fully recognized both by his Department and by the local authorities concerned. The difficulties of securing total removal, however, were considerable, in view of the urgent demands on existing accommodation for the acute sick, for casualties and Service sick, for transferred industrial workers and civil defence personnel, and for others who had an at least equal claim to priority, and the need for keeping a large number of beds immediately available for emergency purposes. Every effort consistent with the other priority demands had been made to assist the removal of these cases; from the London area, for example, it had been possible to remove some 8,000 of the senile or chronic sick so far—4,000 from public assistance hospitals, and 4,000 from those found in the public shelters and temporarily accommodated in London institutions.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

An increase was recorded in the incidence in England and Wales of the principal epidemic diseases with the exception of cerebrospinal and scarlet fevers, the incidence of which declined slightly. In Scotland, in addition to these, decreases were recorded in primary pneumonia and whooping-cough, while dysentery and enteric fever remained at their previous comparatively high levels. The only noteworthy feature in the statistics for Eire is the outbreak of typhus fever which was referred to last week.

Dysentery and Enteric Fever

Although dysentery was recorded in 29 out of the 65 administrative areas, in only 6 were there more than 3 cases, while nearly one-half of the total occurred in a single county—namely, Lancashire 35 (Blackburn 1, Liverpool 3, St Helens 2, Lancaster M.B. 6, Prestwich M.B. 1, Blackburn R.D. 7, Preston R.D. 4, Warrington R.D. 3, Whiston R.D. 8). Increases were reported in Surrey 12 (all in Bagshot R.D., compared with 1 in Banstead U.D. in the previous week) and in Hertford 6 (Watford M.B. 5, St. Albans M.B. 1) against 3 (1 each in Watford M.B., Berkhamsted R.D. and Hemel Hempstead R.D.). The London cases occurred in Wandsworth 4, and Chelsea and Islington 1 each. Essex recorded 4 cases, 2 each in Colchester and Romford M.B. In Scotland 7 areas were affected, including the burghs of Aberdeen 23 and Dundee 6, and the counties of Aberdeen 4, Lanark 4, and Renfrew 3.

Enteric fever was reported in exactly the same number of administrative areas of England and Wales as was dysentery but in none were more than 7 recorded. Counties with over 3 cases were Warwick 7 (Birmingham 4, Coventry 1, Sutton Coldfield 2); Lancaster 6 (Blackpool 1, Liverpool, Manchester, Salford, Lancaster M.B., and Warrington R.D. 1 each); Stafford 6 (Smethwick, West Bromwich, Wolverhampton, Rowley Regis M.B., Lichfield R.D. and Seisdon R.D. 1 each); Middlesex 5 (1 each in the municipal boroughs of Heston and Isleworth, Southall, Southgate, and Willesden, and in Potters Bar U.D.); London 4 (Hammersmith 2, Camberwell and Islington 1 each). In Scotland there were 5 cases of typhoid fever (West Lothian C. 2, and 1 each in the county of Inverness and the burghs of Glasgow and Greenock), and 31 cases of paratyphoid B (24 in Dundee and 1 each in Glasgow and in the counties of Ayr, Lanark, Perth and Kinross, Ross and Cromarty, Stirling, and Sutherland).

Measles and Whooping-cough

Despite the pronounced periodic fluctuations of measles notifications have exceeded those of whooping-cough each week since general compulsory notification was introduced in November, 1939; the ratio has generally been of the order of 3:1 as at present, but it has ranged from something approaching equality when notification was introduced to over 12:1 during last summer. At present every administrative area in England and Wales is affected by both measles and whooping-cough. As regards Wales, Anglesey only is free from measles and Cardigan, Montgomery, and Pembroke from whooping-cough. Essex 1,202 and Kent 1,102 have displaced Lancaster 961 and the West Riding of Yorks 559 as the counties with the highest incidence of measles, while Birmingham 504 and London 393 have similarly displaced Liverpool 107 and Manchester 71, where an epidemic persisted during the greater part of 1940. In these latter two cities whooping-cough has become prevalent—104 and 167 respectively—but it is unlikely that an epidemic of the magnitude of the recent measles epidemic will ensue. While whooping-cough is widely distributed over the whole county prevalence is nowhere very high; only in three counties do notifications exceed those of measles—namely, Cumberland 27 against 6, Northampton 82 against 27, Northumberland 114 against 105.

Typhus

During the week 13 cases of typhus were recorded in the rural district of Kilrush in Co. Clare, Eire. These occurred, with 2 deaths, among the poor overcrowded occupants of 8 out of 12 houses in the Carrowmore area. As these houses were covered with thatch it was considered advisable to order their destruction by fire rather than to attempt disinfection by the usual methods, and to seek fresh accommodation elsewhere after supervision of the contacts in hospital over the period of quar

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 24.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of *Births and Deaths*, and of *Deaths recorded under each infectious disease*, are for: (a) The 126 great towns in England and Wales (London included). (b) London (administrative county). (c) The 18 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Medical News

A meeting of the Medico-Legal Society will be held at 26, Portland Place, W., on Thursday, June 26, at 5 p.m. (following the annual general meeting), when a paper will be read by Dr. Donald Blair on "Alcoholism—a Medico-Legal Survey."

A meeting of the Tuberculosis Association will be held at 26, Portland Place, W., on Saturday, July 5, at 11 a.m. Dr. H. E. Magee will speak on "Wartime Diets and Pulmonary Tuberculosis" and Dr. George Day on "Some Experiments in Diet." At 2.30 p.m. Prof. H. J. Seddon will discuss "Joint Tuberculosis with Special Reference to the Spine and Sacro-iliac Joints."

At a council meeting of the British Medical Students Association in Cambridge on July 5 and 6 the speakers will include Dr. Trueta on "The History of War Surgery," and Dr. Sinclair-Loutit, medical officer, Civil Defence, Finsbury, on "A.R.P. and Students." The agenda for the business sessions includes discussion on the recommendations to be made to the Medical Planning Commission on medical education, in accordance with the invitation of the chairman, Mr. H. S. Souttar. The conference fee is 22s. a head. All are welcome. Particulars from 3, King's Parade, Cambridge. Registration by June 23.

It is anticipated that with the extension of facilities for the treatment of fractures under the Emergency Hospital Scheme there will be an increased demand for trained occupational therapists. The Ministry of Health, therefore, has arranged for the Dorset House School of Occupational Therapy to give special shortened courses of six months' duration to qualified masseuses at the Barnsley Hall Emergency Hospital, Bromsgrove, Worcestershire. About twenty such masseuses from hospitals in the scheme will be accommodated at Barnsley Hall, will receive free board and a personal allowance of £25 for the six-months course. They will not be expected to pay any fees or charges in connexion with the course or with the diploma which they will take at the end, but they will be required to serve in hospitals in the Emergency Hospital Scheme afterwards. The first course will begin on July 1, and hospitals in the scheme are asked to bring the arrangements to the notice of any masseuses they employ. Especially should hospitals with orthopaedic centres at once see whether they can release any masseuse for training with a view to her re-appointment at the hospital afterwards. Forms of application, which should be made promptly, and further details accompany Circular 2389, which the Ministry has sent to local authorities and hospitals.

The name of Dr. John James Mackenzie, medical officer, First Aid Party Depot, Glasgow, has been brought to notice for brave conduct in civil defence.

Dr. Herbert S. Gasser, director of the Rockefeller Institute for Medical Research, will receive the honorary degree of doctor of science at the eighty-eighth commencement ceremonies of the University of Wisconsin on June 23.

Among the items proposed for admission to the new *United States Pharmacopoeia* are whole blood, normal serum plasma, and normal human serum.

According to the *Schweizerische Medizinische Wochenschrift*, the academy for naval medical officers founded at Kiel last year has been removed to Danzig.

By the Workmen's Compensation (Industrial Diseases) Order, 1941, the schedule of industrial diseases (Workmen's Compensation Act, 1925) is extended to include poisoning by chlorinated naphthalene or its sequelae, and poisoning by methyl bromide or its sequelae.

A fully equipped first-aid post, which can easily be converted into a 25-bed emergency hospital, has been established at Tel-Aviv by the Polish Red Cross.

Following representations by St. Dunstan's, the Director-General of Medical Supplies for the Union of South Africa has agreed to arrangements being made for all eye casualties among the British, New Zealand, Canadian, and Australian Forces in the Middle East to be sent to Capetown.

A severe epidemic of measles has recently been reported in Turkey necessitating the closure of schools in different parts of the country.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE NO.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Aitiology Westcent, London*; SECRETARY, *Mediocera Westcent, London*.

B.M.A. SCOTTISH OFFICE: 7, Drumsheugh Gardens, Edinburgh.

QUERIES AND ANSWERS

Ragged Finger Nails

"F.R.S." (Minehead) would welcome suggestions on the following case. A lady, now in the late fifties, is worried about the state of her finger nails. As they grow or try to grow they become rough at the edges and inclined to peel or split, making them unsightly. They have been certainly worse since last Christmas. The skin is dry, but hair is in good condition and the toenails are not affected. The general health is on the whole good, but she has occasional attacks of paroxysmal tachycardia. These are now only infrequent and slight. She has a tendency towards Raynaud's disease, one or two fingers easily going "dead," especially this last winter and spring. Possibly this affects the nutrition of the nails. She is active and energetic and does a good deal of housework and cooking. Digestion is a weak point and she herself puts all her troubles down to "acidity." I am retired and not in a position to know if the restrictions on fats and food generally are affecting other people in this way. The water here is on the soft side.

Post-herpetic Pain

Dr. J. MCNAMARA (Kensington, W.) writes: Your correspondent "M.B., B.S." (June 7, p. 876) asks for advice in treating post-herpetic pain. He will get satisfaction from a pill containing 1/4 to 1/2 grain of extractum cannabis indicae given three times daily. Fifteen grains of phenazone also frequently gives relief.

Income Tax

Share of Trust Income

"A.C.B." is entitled to a share of trust income as from March 4, 1940. He has received a copy of the trust accounts for the period to May 23, 1941, a cheque for £57 and an income tax certificate for the period to April 5, 1941, showing "share of gross income £125, tax paid £50, payments made *nil*."

* * The difference between the periods covered by the account * and the certificate and complications with regard to capital receipts and payments apparently render it impossible to reconcile the figures without detailed examination of the facts. "A.C.B." can, however, assume that the income due to him for the year to April 5, 1941, can be reckoned for income tax purposes as income of that year, at whatever date or dates it reached him, and he can make a claim to repayment accordingly. It is quite possible that a copy of the trust accounts has been lodged by the trustee with the inspector of taxes with whom he deals, and in such a case "A.C.B.'s" inspector of taxes can obtain the necessary particulars through his colleague.

LETTERS, NOTES, ETC.

Abdominal Symptoms after Opium

Dr. JAS. SCOTT (Glasgow) writes: I have been interested in the correspondence in the *Journals* of February 8 (p. 215), March 22 (p. 461), May 3 (p. 655), and May 17 (p. 763). When a medical student, a fellow student recommended me to take 10 grains of Dover's powder for a bad head cold. I did so, and about an hour later I had an uncomfortable feeling in the epigastrium. This lasted a few seconds but rhythmically returned, becoming more severe each time. The pain was not that of an ordinary colic but like the "clawing of an animal" in one's abdomen. Later I got relief by vomiting. Some years later, being particularly anxious to stop a cold, I thought I would again try a Dover's powder. I did so, with the same results as before. This time I thought I would get rid of the powder by means of a dose of apomorphine. I certainly got rid of the Dover's powder quickly, but the apomorphine did not seem to know when to stop and my stomach continued to be "fliped" until I was a collapsed perspiring mass. I have come across two patients with this idiosyncrasy to opium. I was rather nervous when 1/4 grain of morphine was suggested for acute sciatica, but fortunately this gave instant relief with no unpleasant symptoms.

BRITISH MEDICAL JOURNAL
LONDON SATURDAY JUNE 21 1941

GLOUCESTERSHIRE'S CASUALTY SERVICES: EMPLOYMENT OF LOCAL DOCTORS

BY

H. KENNETH COWAN, M.D., D.P.H.
County Medical Officer of Health

The original conception of the A.R.P. casualty services was based on an *ad hoc* service, comprising first-aid parties and ambulances, fixed first-aid posts, mobile units, and, in rural areas, first-aid points. Medical officers were attached to the fixed and mobile posts, but the first-aid parties were intended to proceed to the scene of the incident and there render first aid to casualties before removing them to hospital or the first-aid post or to their homes. It appeared fairly obvious that in practice difficulties were likely to be experienced by the first-aid parties in the correct classification of casualties for disposal, and also because their first aid did not include the administration of drugs to alleviate pain or minimize shock. It was not, however, until actual experience had proved the need that steps were taken to ensure that doctors might be permitted to attend at incidents officially and be paid for their work—in other words, that the general body of doctors throughout the country should have an official place in casualty service schemes.

It has not been difficult in towns and urban areas to supplement official facilities by the employment of doctors at incidents. In rural and semi-rural districts there is an even greater need for a doctor to treat casualties on the spot, but the difficulties of working the local practitioner into the official services are considerably magnified. Distances are greater, it is not possible to assemble a number of doctors at a central post, and arrangements must be made to ensure that the appropriate doctor is notified immediately that his services are needed.

In Gloucestershire a scheme has been devised for the employment of local doctors to supplement the official casualty services in the county, and the doctors have signified their willingness to co-operate. The official services comprise eight fixed first-aid posts, ten mobile units, 150 first-aid points, and ninety-three first-aid parties. The area of the county is some 750,000 acres, and the population with the addition of evacuees is in the neighbourhood of 400,000. The county is divided for A.R.P. purposes into sixteen areas, each with a *local subcontroller, who is in operational control of his area* and has his quota of services to deal with air-raid incidents. Each area is divided into a series of wardens' sectors, with a head warden in charge and an appropriate number of local wardens.

Scheme in Detail

The scheme, which has been adopted by the County Emergency Committee and is now in operation, is as follows:

1. The county has been divided into areas based on wardens' sectors, and groups of parishes have been allocated to local doctors in accordance with the schedule accompanying the scheme.

2. When an incident occurs in which there are casualties the Control and Report Centre, in addition to putting existing services into operation, will notify the appropriate doctor for the locality concerned.

3. The doctor will proceed to the scene of the incident and co-operate with the first-aid party or parties, and, if necessary, request the Control Centre to send the mobile unit.

4. No equipment will be supplied to the doctors in view of the fact that the equipment of the first-aid parties will be available. Drugs which may be used by the doctors—for example, morphine—will be supplied by the doctors from their own stocks, and replacements will be issued from county stores.

5. Arrangements will be made to pay the appropriate fee to a doctor called officially to an incident, in accordance with these arrangements.

The schedule sets out the parishes in each of the sixteen areas, with its appropriate sectors, the name of the head warden, and of the doctor or doctors on call for each sector. A copy of the schedule is in the hands of the subcontroller at the Control and Report Centre, and the relevant extract is also in the possession of each head warden. When the services are put into operation, the Control Centre calls the appropriate doctor to the incident, or the warden may do so to avoid delay and inform the Control Centre of his action. The system is therefore of the simplest nature, does not interfere with the operational control of the other services, and does not admit of confusion as to which practitioner should be called to attend in any particular parish. Subcontrollers, wardens, doctors, and first-aid parties are all aware of their duties, and the doctors of the county now have an official place in the casualty services. Although at present it is not possible to issue steel helmets and civilian duty respirators to doctors, representations on this subject have been made, and it is hoped that the principle of "official personnel" will be applied to medical men in the county and that they will receive a free issue of this equipment as members of the casualty services.

Correspondence

State Medical Service

SIR,—In his letter (*Supplement*, May 31, p. 71) Dr. Oliver Sloan makes a welcome effort to bring the debate on the "free choice of doctor" from the academic to the practical plane. He rightly insists that the "no-free-choice" policy must be defined and its consequences fully recognized. The advantages to doctors of a State Medical Service in the shape of fixed hours, holidays, opportunities for study, secure incomes, and retiring pensions are fully emphasized, but little is heard of the restrictions of individual liberty which may or will qualify this attractive programme; and until these are presented the debate cannot be an informed one. Obviously the State doctor cannot be free to select his area of practice. May he, in addition, be liable to be instructed from above that certain forms of practice are approved and others disapproved? Or that particular forms of illness or of injury—for example, scalp wounds—must be transferred to authorized institutions or selected practitioners? In short, are the present independence and responsibility of the practitioner liable to be displaced by an official code which will direct and review his personal decisions and professional activities? Equally necessary for satisfactory discussion is a definition of the effects of the loss of "free choice" on the liberties of the patient. Will he lose the right to change his doctor? If, when he is ill, he is ordered to hospital must he submit, or take the consequences of refusal? And with fixed hours of duty for the personnel of the medical service, must the sick man be prepared for different advisers at different times in the twenty-four hours? What, if any, are the advantages to be set against these restrictions on professional and public liberties?

Dr. Alfred Cox (*Journal*, May 24, p. 796) is anxious that the broad issue shall be presented to the choice of the profession and of the public. Doubtless he will agree that this choice can be fairly made only when the meanings and consequences of the relevant terms are fully defined and appreciated; no one is more competent than himself to set the opposing points of view in clear contrast. He deems the debate to be an essential preliminary to any attempt at medical planning; let him tell us the Pro and Con.—I am, etc.

Hove, June 1. C. O. HAWTHORNE.

SIR,—Dr. Alfred Cox in his letter regarding the institution of State Medical Service in this country issued virtually an appeal that this important subject should receive a suitable response from the profession. As one of the so-called diehards who opposed the National Health Insurance Act in its present form since its inception, I am equally opposed to the inauguration of a State Medical Service and for more or less similar reasons. My reasons were that National Health Insurance was a gross interference with the freedom of the individual, and it would in no way benefit the general health of the worker: Friendly Society statistics can demonstrate that fact; that National Health Insurance would lower the prestige of medical men and the practice of medicine to a commercial undertaking, which it has done, and has also lowered the standard of medical practice; that free choice of doctor was an anomaly and only existed on paper: for a patient to change his doctor required so much red tape that patients would refuse to use it, which is the case.

But we who opposed National Health Insurance saw in this measure the furtherance of State socialism, which would extend its growth and swamp the whole edifice on which the democratic ideal was founded. Would anyone deny that freedom of patient and medical man has been restricted, and that such restriction of freedom is now being increased by extending the Act to "black-coated workers"? During the present epoch there is a growing tendency for tradition, which holds much of benefit to the human race, to be swept aside and replaced by something of an experimental order which has nothing but a hypothetical foundation.

Medical officers of health in general appear to be more or less unanimous in their support of the establishment of a State Medical Service: but it may be pointed out that those members of the profession, although doing necessary work in their particular sphere, have little or no experience of the complexities of general medical practice, where patients are not treated *en masse* but as individuals possessing various idiosyncrasies which only experience, keen observation, and sympathetic understanding can treat.

It is time, I think, that medical men, who are supposed to represent an educated section of the community, should enlarge their vision. They might see, in further extensions of National Health Insurance and the establishment of a State Medical Service, merely a further inroad on the freedom of the individual and a step nearer a totalitarian system, which is the real enemy of a true democracy and which we are at present shedding much blood and treasure to destroy. We have not yet attained the democratic ideal; but successive Governments within recent years have been steering in the opposite direction and making men and women mere vassals and governed by a code book. If we still adhere to the gospel that democracy is essential, which I hold it to be, for the highest welfare of humanity, it is necessary that the situation be reviewed, and before introducing new measures these should be subjected to careful analysis and made to conform entirely to the democratic State; otherwise we shall drift further on the road to complete State domination of the individual.—I am, etc.,

Edinburgh, June 1. FREDERICK PORTER.

SIR,—It is interesting to read the many letters that you have published on a State Medical Service, and I hope that the members of the Medical Planning Commission are taking steps to file the many suggestions that have been made. It is also encouraging to note that efforts have already been made to widen the representation on the Commission. It would appear that some, at least, of your correspondents pay too much attention to the details of a plan which has barely been conceived, instead of aiming at certain principles which should guide the profession in formulating a scheme for State Medical Service. I should like the opportunity of putting down one or two of the principles that I feel we should aim at.

Our first aim should be unity within the profession. There seems little doubt that each branch of the profession has its own axe to grind, whether it be the specialist branch, the general practitioners, medical officers of health, officers of the State-aided hospitals, or any other branch not named, and I should like to put forward a plea that we should remember our common origin, and that this should promote a bond between us all. As an example of this lack of unity I would suggest that it is impossible for medical officers of health, who are paid by county, urban, or rural district councils, to give whole-hearted support to the profession and to the country at large when their means of livelihood depend upon their good will with their respective councils. They should be part of the State Medical Service and paid by the State. It would be a great help in attaining this unity if all doctors after qualification served a year doing hospital appointments and then some time in general practice before passing into one of the special branches of medicine mentioned above; and they should be chosen for these respective positions according to their aptitude and qualifications, perhaps by their colleagues.

The second aim should be to divorce medical benefit from sickness benefit, so that the profession would have sole and complete control of the State Medical Service. The implications of this are obvious, at any rate to those who have served as National Health Insurance practitioners.

Thirdly, we ought to aim at preserving private practice within the State Medical Service. This can be done by following the procedure carried out in Denmark, the country which before its occupation was the most advanced democratic country in the world, and whose conception of State Medical Service appeals to me as the nearest approach to the ideal. The first thing the Danes recognize is the great difference between town practice and country practice. In their large towns the area is divided into sectors, and a doctor is appointed to each sector by the Government. Every individual in the sector can obtain the State Medical Service from the doctor of that sector, but the individual can go privately to one of the other State doctors in another sector if he or she wishes to do so. This preserves the independence of the individual and the status of the medical practitioner.—I am, etc.,

Wadhurst, Surrey, June 1. H. J. FULLER.

SIR,—As the advocates of a State Medical Service have become rather vocal in your columns of late, may I take the opportunity to endorse the opinions of Dr. D. Murray Bladon in his very sensible letter in the *Supplement* of June 14 (p. S2). During fifteen years of medical practice I have never yet come across a medical practitioner who desired such a scheme. Moreover, the treatment that insurance practitioners have received from the Ministry of Health should make them very wary indeed of any extension of the panel system to dependants.—I am, etc.,

Leamington Spa, June 14. SYDNEY D. POVEY.

Overworked and Underworked Doctors

SIR,—It must be evident by now that neither the Government nor the B.M.A. is going to do anything about this problem, so either it will continue and some men die of overwork whilst others face bankruptcy, or the rank and file of the profession must combine locally to help themselves. For this purpose I suggest the temporary formation of big partnerships in the evacuated areas, a dozen or more practitioners joining forces for the duration of the war, and, say, a year after it. No money need change hands, but each man would draw a share proportional to his pre-war income. Suppose it was found that six men could run the combined practice, each other member of the partnership would take up an assistantship in the busy rural areas, pay his salary into the practice pool, and draw from it his proportion of the total earnings after the practice expenses had been met.

There will doubtless be many who will object to leaving their homes and going off into the country to act as assistants, but there is no reason why partners should not relieve each other from time to time. And where salaries are concerned, a big firm would have better bargaining power than individual men. After the war the "rural assistants" would come back to the town, and would have a year of partnership in which to pick

up their own practices again before splitting up into smaller units should they wish to do so.

Of course, the question of death or disablement of one or more partners would have to be faced. Each big partnership would work out its own scheme. The big partnership could be started anywhere at any time. No partner need know the pre-war income of any other partner; he would simply submit his audited accounts to the partnership auditor, who would assign him an index denoting his share of the total income. The incomes would be smaller than pre-war, as the "rural assistants" would be earning less, but they would probably be more than they are now, and both the town and the over-worked country doctors would be able to get half-days, and possibly occasional holidays.—I am, etc.,

FREWEN MOOR.

Norwich, June 2.

Functions of Works Doctors

SIR,—The rapidly developing situation arising from the widespread appointments of works doctors needs attention before it is too late. I have within the last week had the following experiences. A panel patient has been treated for six days by a works doctor and then referred to me. A panel patient has been given a London panel prescription, although she lives and works in Middlesex. The prescription was signed by the works doctor. Many obvious points are raised here. Another panel patient had in her possession two panel prescriptions—one from the works doctor and one from me.

The final case is the most important. I saw a panel patient for the first time on Tuesday and arranged for her to go to hospital on Wednesday for investigation. She attended and time for x-ray examination was fixed. Later in the day she returned to work and was seen and examined by the works doctor, who wrote me a letter, suggesting a diagnosis and an investigation at another hospital. I understand that the rule that a doctor must not examine a patient already under treatment still holds, and suggest that the profession must act very quickly if it is to stop a very dangerous situation develop-ing which can do no good to anybody, least of all to the unfortunate patient.—I am, etc.,

R. W. COCKSHUT.

Hendon, N.W.4, June 5.

Free Choice of Doctor

SIR,—Dr. Alfred Cox has contributed (May 24, p. 796) one of his always valuable letters on the question of free choice of doctor. In his concluding paragraph he just refers to the old tradition of the family doctor, which has always been regarded as almost a principle of medical practice in itself. No one, I am sure, will dispute the value of each of these ideals, or the importance which should attach to them in the consideration by the Planning Commission—or any other body—of the future of the medical profession. But I think it is very seldom that it is recognized that under modern methods of medical practice these two ideals are really antagonistic and very difficult to reconcile in practice. I maintain that it is so.

In the really rural districts the family doctor tradition is more likely to survive; not so in the urban areas. Dr. Cox says: "I stand for the right to choose my own doctor for myself, and believe it to be in the general interest." That is undoubtedly so. But I would ask my old friend: What would his father have said to him if at the age of 16 Alfred had said: "I'm tired of old Dr. Brown: you can go on having him if you like, but if I want a doctor I am going to have Dr. Jones"? I know what my father would have said to me; and he would have been right. But that is largely the position to-day. The great majority of the population of this country are insured persons under the N.H.I. Acts. As such they enter into insurance at the age of 16, when they are supplied with a medical card entitling them to take it to any panel doctor whom—for any reason—they prefer. Now is it likely that at that age they will be in a better position, in their own interests, to make a good selection than the parents who have had one doctor for many years to attend themselves and the children? I believe the truth to be that where the new entrant into insurance selects a different doctor from the one who has been the family doctor all along, the last thing he or she thinks about is the worth of a doctor from the pro-fessional standpoint. Propinquity, the desire for change, the fact that some friend has said what a nice fellow that new young doctor round the corner is—these are the considerations that prompt them to exercise their free right of choice if they ever give any consideration to the matter at all.

All this may not apply so much to the better-off class of patient. There the family doctor tradition is more likely to continue. The young entrant into insurance is quite content to place himself on the panel of the doctor who has attended him all along whenever he needed attention. And when he becomes older and leaves the old home to set up for himself, and perhaps is no longer an insured person, he is more likely to stick to the old practitioner than to choose another merely in order to exercise the grand privilege of choosing his own doctor. If he wants to do so, of course he has the right of every free man to his own free choice. But as things are I fear the principle of "free choice" has become more a sort of shibboleth or slogan than a principle to be appreciated and put into ordered practice by those most concerned.

In considering all or any suggestions that may be put forward for ensuring an adequate Medical Service for all the inhabitants of this country, I think attention should be paid to whether or how far it is possible to reconcile these two matters; to afford at least to all who are old and experienced enough to exercise it the right of free choice of doctor; and at the same time to encourage the maintenance of the old tradition of the family doctor. And I believe that even under some form of State Medical Service much could be done to reconcile these two interests, to the benefit alike of the public and the pro-fession.—I am, etc.,

JOS NELSON.

Hull, June 2.

Medical Services of H.M. Forces

Appointments

ROYAL NAVY

Surgeon Lieut. J. Lees to be Surgeon Lieutenant-Commander.

ROYAL NAVAL VOLUNTEER RESERVE

Probationary Temporary Surgeon Lieuts. A. E. A. Shaw, A. M. Blackstock, F. McL. McGown, and G. A. S. Anthony, to be Temporary Surgeon Lieutenants.

ARMY

Lieut.-Colonel (temporary Colonel) S. M. Hattersley, M.C., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieut.-Colonels C. E. W. S. Fawcett, retired pay, C. Seaife, retired pay, and D. P. Watson, D.S.O., retired pay, have reverted to the rank of Major at their own request whilst employed during the present emergency.

Lieut.-Colonel D. C. G. Ballingall, M.C., has retired on retired pay on account of ill-health.

Majors (Acting Lieut.-Colonel) J. M. MacKenzie, O.B.E., M.C., and (Temporary Lieut.-Colonel) H. J. Benstead, M.C., to be Lieutenant-Colonels.

REGULAR ARMY RESERVE OF OFFICERS

ROYAL ARMY MEDICAL CORPS

Captain (temporary Major) P. G. Tuohy to be Brevet Major, under the provisions of Article 163, Royal Warrant for Pay and Promotion, 1940.

Lieut. (War Substantive Captain) C. G. Harper, from Gordon Highlanders, Reserve of Officers, to be Lieutenant (War Substantive Captain).

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major W. J. C. Watt, having attained the age limit, has relinquished his commission and retains his rank.

War Substantive Major N. H. Leslie has relinquished his commission on account of ill-health and retains his rank.

Captain E. H. Jaques has relinquished his commission on account of ill-health.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

Captain B. P. O'Hara has resigned his commission (Substituted for the notification in the *Supplement* to the *London Gazette* dated May 13.)

War Substantive Captains D. Barclay, O. G. Bark, G. Henry, J. E. Ryan, and K. R. Thomson have relinquished their commissions on account of ill-health.

Temporary Captain J. L. Arran has relinquished his commission on account of ill-health and resumes the rank of Captain.

Lieut. G. A. Beggie to take rank and precedence in R.A.S. Corps and in the Army as if his appointment as Lieutenant bore date April 2, 1941.

Lieuts. R. E. Newman and W. Campbell have relinquished their commissions on account of ill-health.

The surnames of Lieuts. R. W. Meller and A. W. Kinchant are as now described and not as stated in the *Supplement* to the *London Gazette* dated May 2.

The notification regarding Lieut. A. W. Hammer in the *Supplement* to the *London Gazette* dated May 2 is cancelled.

Major H. H. R. Bayley, from temporary commission, to be Lieutenant.

To be Lieutenants: J. V. Craig, J. S. Leigh, T. T. Micin, W. J. Wright, J. Janner, R. Kells, W. R. Kenyon, R. V. Rhoda, G. G. Robertson, H. H. Davies, D. Mitchell, J. G. O'Mahoney, P. V. Bailey, W. N. Calder, J. A. Learner, A. Young, J. F. E. Waller, A. H. Bailled, W. N. Lacey, H. H. Davies, R. L. G. Dawson, W. G. Edwards, W. A. Frost, J. W. Lacey, A. M. Beemer, L. B. G. S. Mansell, A. Ramage, H. Upshon, D. Adler, A. M. A. Beemer, A. J. Berry, H. A. Blackford, J. H. Brodie, C. A. Brown, R. Christie, R. M. Brennan, W. Feries, J. W. Gorcsny, P. R. Graves, T. W. Green, R. M. Halahan, J. J. A. Hamilton, N. A. Jewers, F. F. King, A. W. C. Lobban, J. G. Macleod, A. Noble, B. Oppenheim, W. L. Paterson, A. M. Stewart, R. Bamber, G. B. Macaulay, A. Murray, A. L. Rawson, R. J. Rowland.

G. [illegible] 'alder, J. H. C. Corr, J Dawson, A. M. Dickson, W. [illegible] P M James, K. C. Kershaw, A. M. MacDonald, G. [illegible] ''cNicol, A. L. R. Mayer, G. A. Mogey, J. J. O'D[illegible] J. N. Stirling J C. T. Sykes, A. W. Douglas, J. J. McCarthy, D. P G. Paisley, F. J. Beaton, J. R. Bodington, E. W. Jones, E. J. Kerr, M. Leibson, J. E. T. Munn, F. L. H. Voller, L. A. C. Wood, R. B. N. Wilsdon, H C. Allan M. Beaton, D. Belchover M G. Braham, R. H. Butcher, R G. Drummond, A. A Evangeledes, A. C. C. Evans, A. Franklin, F. J. Gillingham, A. Giordani, A S Hollins, A. G Hooker, J. L. Linacre, R. W. McClements, A. McConnell, C. T Macdonald, A. F. McGlashan, I. H Milner, W. J. Mohat, W. H. Murray, P. O'Callaghan, F. L. Potter, J. K. Samuel, W. M. Smith, J. B Sugden, T. D. V. Swinscow, W. T. Thom, J. R Tocher, L. Werbeloff, G. R Wightman, D. Wilson.

ROYAL AIR FORCE

Group Captain H. A. Hewat to be Air Commodore (temporary)

Wing Commanders T. J. Thomas, W. E. Barnes, J D. Leahy, E. C K. H Foreman, and W. J. G. Walker to be Group Captains (temporary)

Squadron Leaders R. S. Topham, L. P. McCullagh, D. A. Wilson, H. C. S Pimblett, J. Kemp, P. J. McNally, G. H. J. Williams, J. F. McGovern, C. Crowley, and G. O. Williams to be Wing Commanders (temporary)

Flight Lieuts. F. I. G. Tweedie, A. M. Weston, J. F. Sandow, L. E. A Dearberg, G. H. Stuart, L. M. Corbet, C. F. R. Briggs, and A. S. Burns have been granted the War Substantive rank of Squadron Leader.

Flight Lieuts. J H Cullinan, J. L. Walsh, J. F. Dales, L S. Everett, H. Bannerman, G. Gilchrist, G. H. Morley, J. C. Blair, A. W. Smith, J. W. Patrick, J. S. Wilson, H. L. Wilcox, and P. A. Cooper to be Squadron Leaders (temporary).

Miss Patricia G. Cooper and Miss Sheilagh M. C. Murray have been appointed as Medical Officers with the relative rank of Flying Officer.

ROYAL AIR FORCE RESERVE

Squadron Leader A. T. G Thomas to be Wing Commander (temporary).

Flight Lieuts. R. F. T. Grace, J C. Smyth, D Magrath, R. F W Fisher, W. J. Hutchinson, and E. Donovan have been granted the War Substantive rank of Squadron Leader.

Flight Lieuts. C. McC Jones, W. D. Miller, E. G. Howell, L. A. Rice, R. F. MacLatchy, J. L. Groom, A. R. French, E. W. B. Griffiths, W. A. Beck, M. D. Rawkins, and T. A G Hudson to be Squadron Leaders (temporary).

Miss Mary Calvert and Miss Kathleen E. A. Smith have been appointed as Medical Officers with the relative rank of Flying Officer.

AUXILIARY AIR FORCE

Squadron Leader J. C. H Allan to be Wing Commander (temporary)

Flight Lieut. J. H. Williams has been granted the War Substantive rank of Squadron Leader.

Flight Lieuts. D. A. Smith, I. A. G. L. Dick, C. W. Kidd, J. P. Huins, I. R. Jones, T. McM. Boyle, J. H Attwood, W. D. Coltart, and W. D. Pecock to be Squadron Leaders (temporary).

Flying Officers R. J. H. Raines and J. D Crerar have been granted the War Substantive rank of Flight Lieutenant. (Substituted for notifications in the *London Gazette* of October 8, 1940, and May 28, 1940, respectively.)

AUXILIARY AIR FORCE RESERVE OF OFFICERS

Flight Lieuts. A. C. Fraser and H. W. Walter to be Squadron Leaders (temporary).

ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron Leaders C. W. Flemming, G. L. M. McElligott, F. W. Roques, J. F. Simpson, D. H. Brinton, S. Cade, R. R. Trail, J. G. Skeet, T. K. Lyle, E. T. Cato, N. K. Henderson, and R. N. Ironsido to be Wing Commanders (temporary).

Squadron Leader J. M. Bickerton has resigned his commission.

A. G. Cross and A. M. Stewart-Wallace to be Squadron Leaders

Flight-Lieuts. H. C. Purcer-Smith, G. P. Smith, A. W. Badenoch, G. A. Jamieson, J. T. Linklater, G. M. Rose, H. F. Squire, R. D. Bruce, T. G. Hovenden, T. J. B. A. MacGowan, L. V. McNabb, D. F. E. Nash, H. B. Bagshaw, H. W. Dryerre, F. P. Forrest, J. A. Pecock, K. J. Thomson, H. McD. Walker, A. G. Wilson, and C. J. Shortall to be Squadron Leaders (temporary).

Flight Lieuts. L. G. Scoular, J. Wingate, K. Robson, R. W. Durand, J. Tate, and W. Milligan have been granted the War Substantive rank of Squadron Leader.

F. J. P. O'Gorman to be Flight Lieutenant.

Flying Officers A. H. Baynes, A. Maclaine, E. S. Nicholson, W. H. C. Spooner, W. A. Jones, E. A. K. Hoppins, H. I. Baigel, T. W. Branch, W. P. D. Logan, R. S. Nicholson, D. L. Bennett, A. M. Goldthorpe, J. M. MacCormack, A. O'Connor, I. H. Taylor, J. S. Wood, B. H. Goodrich, G. A. Scott, S. Bender, D G Evans, A. H. Thomson, H. D. Welch, and C. F. Bose have been promoted to the War Substantive rank of Flight Lieutenant.

Flying Officers L. O'N. Knox, N. K. B. Kimbell, and J. N. MacDonald have been granted the War Substantive rank of Flight Lieutenant.

To be Flying Officers: D W. R. Ashby, G. R. Bedford, R. F. Browne, W. Cookson, W. N. Crow, S. Duff, P. McA. Elder, C. G. Fagg, K. M. Fox, H. R. L. Fraser, R. W. G. Grindlay, M. J. Hackett, F. W. Parke, E. A. Pask, R. Robertson, R D. Sloan, C. E. Waterman, J. N. Williams.

Flying Officer R. A. C. Macnair has resigned his commission.

The notification in the *London Gazette* of May 23 concerning E. E. Phillipp should have read E. E. Philipp.

DENTAL BRANCH

J. C. McDougall to be Flying Officer.

COLONIAL MEDICAL SERVICE

The [illegible] ounced: F. I. C. Apsted, M.B., B.S., and H[illegible] .P., Medical Officers, Sierra Leone; M. A. [illegible] I. Turner, M.R.C.S., L.R.C.P., W. J. Tyson, [illegible] M.R.C.S., L.R.C.P., Medical Officers, Malaya [illegible] Medical Officer, Nigeria; A. J. Have, M.D., [illegible] t; E. J. Thomas, M.R.C.S., L.R.C.P., Pathol[illegible] Chellapah, O.B.E., M.R.C.S., L.R.C.P., D.P.H., Director of Medical and Sanitary Services, Ceylon; M. A. Cave, M.R.C.S., L.R.C.P., P. R Cooper, M.B., Ch.B., G. R. Wadsworth, M.B., Ch.B., and R. W. Palmer, M.R.C.S., L.R.C.P., Medical Officers, Gold Coast; C. W. Davies, M.R.C.S., L.R.C.P., D. H. Manson-Bahr, M.R.C.S., L.R.C.P., and A. J. Walker, M.B., B.S., Medical Officers, Kenya; D. W. Horn, M.B., Ch.B., Medical Officer, Gambia; W. N. Kenrick, M.R.C.S., L.R.C.P., Medical Officer, Uganda; J. H. Strahan M.B., B.Ch., D.P.H., Malaria Research Officer, Federated Malay States.

B.M.A. LIBRARY

The following books were added to the Library during April and May, 1941:

Albee, [illegible] : Bone-graft Surgery in Disease, Injury and [illegible]

Avery, [illegible] cers. 1941.

Bainbri[illegible] Physiology. Ninth edition, edited and revi[illegible]

Balleng[illegible] Rhinology and Laryngology. 1940.

Blackl[illegible] : Guide to Human Parasitology for Medical Practitioners. Fourth edition. 1940.

WILTSHIRE BRANCH, SWINDON DIVISION.—At Victoria Hospital, Swindon, Wednesday, June 25, 8.30 p.m. Dr. Percy Phillips: Air-raid Experience in Bristol.

Postgraduate News

A course of lectures and practical demonstrations on "The Treatment of Fractures, with Special Reference to War Conditions" will be given by Mr R Watson-Jones in the Department of Surgery of the British Postgraduate Medical School, Ducane Road, Hammersmith, W., from Monday to Friday, June 23 to 27, both dates inclusive, from 10 a.m. to 5 p.m. each day. The course is limited to a maximum of 30 students, and applications should be submitted to the Dean. The course will only be held if a minimum of 15 students apply. The fee for the course is £5 5s., but a limited number of Officers of the armed Forces will be admitted free on receipt of a leave certificate.

The Fellowship of Medicine announces the following courses for Final F.R.C.S. Candidates: (1) Clinical demonstrations, 2 p.m., Wednesdays, July 2 to 23; (2) Revision course, daily, 10 a.m., July 7 to August 1; (3) Practical operative surgery, Mondays, Thursdays, and Fridays, 2 p.m., July 7 to August 1; (4) Urology course, Thursdays, 2.30 p.m., August 7 to 28; (5) Week-end course of clinical demonstrations, Saturday afternoon and Sunday morning, July 12 and 13, at King George Hospital, Ilford.

WEEKLY POSTGRADUATE DIARY

BRITISH POSTGRADUATE MEDICAL SCHOOL, Ducane Road, W.—*Daily*, 10 a.m. to 4 p.m., Medical Clinics Surgical Clinics and Operations, Obstetrical and [illegible] ions. *Daily*, 1.30 p.m. Post-mortem [illegible] Course by Mr. R. Watson-Jones com[illegible] .tric Clinic, Dr. R. Lightwood. *Wed.*, [illegible] onference (Medical). *Thurs.*, 2 p.m., [illegible] .in; 2 p.m., Radiological Demonstration, [illegible] n., Clinico-pathological Conference (Sur[illegible] Conference (Gynaecological); 3 p.m., Sterility Clinic, Mr V. B. Green-Armytage.

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATION, 1, Wimpole Street, W.—Royal Chest Hospital, City Road, E.C., *Wed.*, 3.30 p.m., M.R.C.P. Course in Heart Diseases.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Section of Psychiatry—Tues., 4.30 p.m. Paper by Dr. Eliot Slater: Amnesic Syndromes in War.

Section of Urology.—Thurs., 5 p.m., Clinico-pathological meeting. Specimens.

Section of Orthopaedics.—Sat., 2 p.m., at Park Prewett Hospital, Basingstoke. Annual General Meeting 2 p.m., and 4.30 p.m. Papers

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos Street, W.—Tues., 2.30 p.m. Discussion: The Necessity of the Clinician making the Best Use of Laboratory Facilities in the Diagnosis of Venereal Diseases, and Simple Methods of doing so. To be opened by Dr. I. N. Orpwood Price.

SHAFTESBURY MILITARY HOSPITAL MEDICAL SOCIETY.—*Tues.*, 3 p.m., Major J. C. Thomas, R.A.M.C.: The Control of Air-borne Infections in Hospital Wards.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following vacant appointments are announced: Tipton (Staffordshire); Launceston (Cornwall). Applications to the Chief Inspector of Factories, 28, Broadway, S.W.1, by June 24.

APPOINTMENTS

BURN, J. L., M.D., D.P.H., Medical Officer of Health to the City of Salford.

GUNN, D., M.B., Ch.B., Examining Factory Surgeon for the Loanhead District (Midlothian).

HUGHES, T. Ll., M.D., D.P.H., Medical Officer of Health, County Borough of Barnsley.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should be forwarded with the notice, authenticated with the name and address of the sender, and should reach the Advertisement Manager not later than the first post Tuesday morning to ensure insertion in the current issue.

MARRIAGE

TAYLOR—LATTER.—On Saturday, May 24, at Chelsea, Arthur Gordon Taylor, L.D.S.Eng., to Rosalind Brackenbury Latter, M.B.(N.Z.), M.R.C.P.Lond.

BRITISH MEDICAL JOURNAL

LONDON SATURDAY JUNE 28 1941

THE REDUCTION OF DUST-BORNE BACTERIA IN THE AIR OF HOSPITAL WARDS BY LIQUID PARAFFIN TREATMENT OF BEDCLOTHES

BY

JOHN C. THOMAS

Major, R.A.M.C.; Officer in Charge of a Military Laboratory

AND

M. van den ENDE, M.B Capetown, Ph.D.Camb.

National Institute for Medical Research, Hampstead

Until recently it had been commonly accepted that respiratory infections are spread direct by droplets disseminated from the upper respiratory tract of infected persons or carriers. Large droplets (0.1 to 1 mm.) may be sprayed for a distance of fifteen feet, but, by reason of their size, fall rapidly to the ground. Small droplets (less than 0.1 mm.) evaporate before reaching the floor and may remain floating in the air for long periods as nuclei of small clumps or as single bacteria (Wells and Wells, 1936).

That there is a third possible channel of infection, mainly on dust, is becoming increasingly obvious. It is with this method of spread that we are particularly concerned in this paper. Bloomfield and Felty (1924) demonstrated that there is relatively little or no horizontal expulsion of streptococci from the respiratory tract of infected persons. More recently (1940) Hare has shown that a considerable number of organisms stream diagonally downwards. These may be caught on the bedclothes or fall to the floor, where they dry, and may be re-projected into the air with bed-making or sweeping. Cruickshank (1941) and Thomas (1941a) have shown that large numbers of haemolytic streptococci do accumulate in hospital dust, while Wright, Shone, and Tucker (1941) have demonstrated diphtheria bacilli in the dust of their isolation wards. Until the relative responsibility of each of these methods of spread is finally determined, and especially in the abnormal conditions in which we are living to-day, it is necessary to provide adequate safeguards against all three.

We have previously shown that a very large percentage of aerial contamination from dust can be removed by treating wooden or linoleum-covered floors with spindle oil (van den Ende, Lush, and Edward, 1940; Thomas, 1941b). Van den Ende, Edward, and Lush (1941) showed that both the amount of dust and the numbers of streptococci released from infected bedclothes by beating under experimental conditions were reduced by 90 to 100% by previous treatment with a 30% solution of liquid paraffin in white spirit. This treatment of bedclothes, together with the application of spindle oil to the floor of a ward, has been found by van den Ende and Spooner (1941) to reduce the number of organisms present in the air of the ward throughout the day; the increase in the bacterial content of the ward usually accompanying bed-making and sweeping was reduced to a minimum. The ward in which their experiments were performed was, however, not ideal for the purpose, because of the interchange of dust which occurred between adjacent sections of the ward, and, furthermore, the number of pathogens recovered from the air was small.

This paper describes experiments in both large and single-bed hospital wards, in some of which there were enough haemolytic streptococci in the air to allow them to be used as indicator organisms. Owing to the nature of the infections treated in the wards it was also possible to regulate the experimental conditions much more accurately.

Bacterial Counts

1. *Air.*—The medium employed in all our experiments was 1 in 500,000 gentian-violet blood agar. For air sampling, plates were exposed in slit-machines (Bourdillon, Lidwell, and Thomas). The gentian-violet medium has been shown to be relatively selective for haemolytic streptococci (Garrod, 1933), and reduces the growth of air-borne saprophytes by 95%. Continuous counts were made with the machines adjusted to suck 1 c.ft. of air per minute. In all our diagrams each vertical block represents the count of organisms collected from 10 c ft. of air in ten minutes. Altogether 647 plates were used for these experiments.

2. *Dust.*—Dust samples were collected into sterile bottles and freed from obvious mineral matter, such as pieces of grit and coal. Amounts of 100 mg. were shaken for 15 to 30 seconds in 10 ml. of sterile nutrient broth and then allowed to settle for fifteen minutes. At the end of this period of clarification 2 ml. was transferred to a second bottle containing 18 ml. of broth and again shaken. Varying amounts (0.5 to 0.05 ml.) of this final dilution (0.1 mg. dust per ml.) were plated out into gentian-violet blood agar in duplicate. In a few cases counts of the total organisms were made on serum agar. The counts can, of course, only be regarded as approximate, and probably low, as we have counted as single organisms what may have been clumps of organisms adherent to one another or to dust particles.

3. *Bedclothes.*—Counts were made with a special extractor designed by one of us (M. v. d. E.). This consists of two flanged aluminium plates, fitting closely together with a rubber ring and held by three screw clamps set in U-shaped arms to allow for a fringe of blanket when the apparatus is assembled. In the lower plate is an inlet attached to a 50-ml syringe by a length of rubber tubing;

in the upper plate is an outlet fitted with a tap and a small glass funnel (Fig. 1). The whole is sterilized by autoclaving.

For use the two halves of the chamber are clamped on to any desired part of the material to be tested, and 50 ml. of nutrient broth is drawn backwards and forwards through the fabric some twenty or thirty times. Finally, a little of the broth is driven upwards into the funnel, the tap is closed, and aliquot parts are plated out into gentian-violet blood agar.

Tests of Efficiency of Blanket-sampling Apparatus

Known volumes of a serum-broth culture of haemolytic streptococci (Group C) were spread over the centre of 6-inch and 1-inch squares of woollen blanket material; at the same time, equal volumes were placed in empty sterile Petri dishes. The 6-inch squares were extracted with 50-c.cm. amounts of broth by means of the special

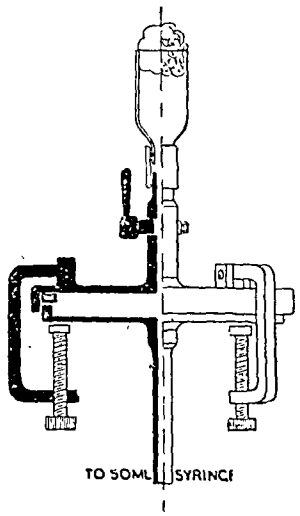

FIG. 1.—Apparatus for making bacterial counts on bedclothes or fabric materials.

apparatus, each 1-inch square was mechanically shaken with 50 c.cm. of broth in a stoppered bottle containing glass beads, and to each Petri dish was added 50 c.cm. of broth. One set of extractions was made immediately, and the second after the infected blanket squares had been dried in high vacuum over P_2O_5. The streptococci in the broth extracts were counted by the technique adopted by Miles

Table showing Experimental Recovery of Streptococci from Blankets

Impregnation	Method of Sampling		Count from Petri Dishes
	With Special Apparatus (Fig. 1)	Mechanically Shaken	
Broth culture dropped on to blanket: (a) Sample immediately .. .. .. (b) Sample after drying over P_2O_5 ..	59 millions 64 ..	60 millions 80 ..	79 millions 64 ..
Exposure to uniform mist of streptococci	5,000	5,250	

and Misra* (1938). A second test was done with circular pieces of the same woollen blanket exposed to a uniformly distributed aerosol of streptococci in a sealed room. One set of these samples, each with a surface area 4.9 sq. in. (equal to the area extracted by the special apparatus), was extracted by mechanical shaking with broth. The other samples, which were larger, were extracted with the special apparatus. The results, which are given in the accompanying table, show that there was no significant difference between the numbers recovered by the use of the special apparatus and those recovered by thorough shaking with broth. The number of streptococci recovered from hospital blankets should therefore give a fairly accurate indication of the numbers actually present.

Treatment of Bedclothes with Liquid Paraffin

For our preliminary experiments complete sets of bedclothes (1 wool-cotton counterpane, 3 blankets, 2 sheets, 1 draw-sheet, 2 pillow cases, and 1 pair pyjamas per bed) were treated at Hampstead. For our large-scale ward experiments sixteen sets were treated in the hospital laundry. Van den Ende, Edward, and Lush showed that

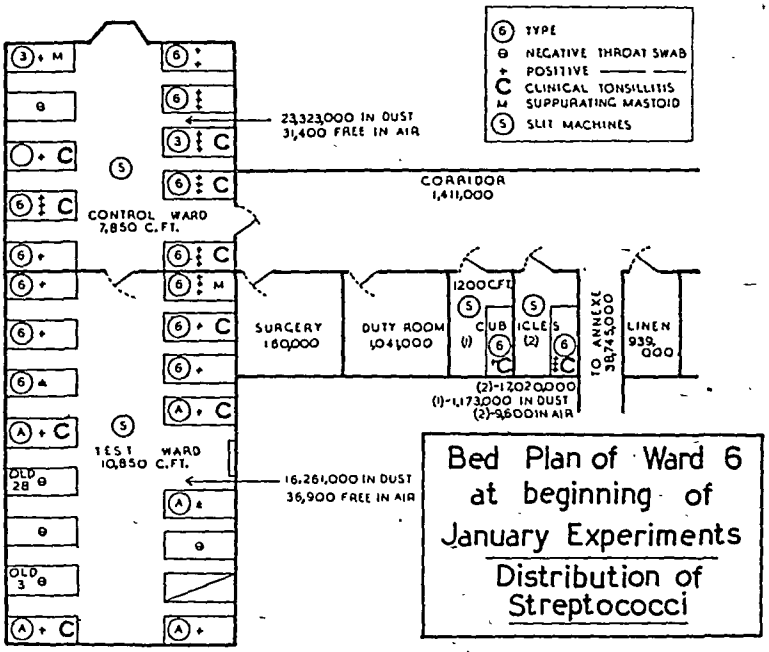

FIG. 2.

the ideal concentration of oil for treating bedding is 30%, and that with this concentration the final bedding is not oily to touch and yet contains an effective proportion of oil (blankets, 3%; bed-linen, 6 to 7%). One difficulty experienced was that the blankets absorbed so much of the parent liquor that only a few could be processed at one time unless larger volumes of oil were available.

Our "oiling party" consisted of Cpl. T. Bury, R.A.M.C., and seven others. Treatment of 160 articles (48 blankets, 48 sheets, 32 pillow-cases, 16 counterpanes, 16 pair pyjamas) fully occupied the party for three hours. Thirty gallons of the 30% solution of liquid paraffin in white spirit was placed in a large tank. The bedclothes were soaked in this solution, partially wrung out by hand, and then transferred to a hydro-extractor. Centrifuging was continued until only a thin trickle of the solution was running from the outflow. The outflow from the hydro-extractor was recovered by blocking the outlet drain and by baling from the trough while the machine was running, and was then returned to the soaking-tanks. From the hydro-extractors the bedding was put through a drying chamber which had previously been heated. In order to minimize fire risk the heat was turned off immediately before placing the bedclothes into the dryer, but the draught fans were kept in operation. Although in this experiment the sheets were not ironed, previous experience has shown that this can be done with

*This technique involves the use of glass capillary pipettes which deliver 50 drops of broth per c.cm. (see Wilson, 1922). Our pipettes were specially made for us with parallel-sided capillaries drawn to the required dimensions, and sealed into 6-mm glass tubing.

an ordinary single-bed calender. Reduction of the temperature of the steam bed minimizes the loss of oil on the roller pads.

Ward Trials

The ear, nose, and throat wards, in which our experiments were performed, consisted of a main ward divided by a glass partition and door into a 16-bed and a 10-bed section (Fig. 2). Each could be completely isolated. The larger section was used as a test ward and the smaller for control experiments. The floors in both sections were treated with spindle oil. Small single-bed isolation cubicles, each of 1,200 c.ft. capacity, were also used. Consecutive air samples, each of 10 c.ft., were taken with a slit-machine—the first three samples usually during a quiet period, to determine the minimum number of bacteria in the air. During the ten minutes in which the fourth air sample was taken the floors were swept in order to show that no dust could be raised from the oiled floors. During the sixth ten-minute period beds were made. Sampling continued until static conditions again obtained. Simultaneous counts were made in both test and control wards. To overcome the difference in size of the two wards, we made more beds in the test ward than in the control ward on each occasion. Cubicle experiments were carried out as suitable cases presented throughout the whole period.

Distribution of Streptococci in the Wards

It was found that in any ward in which there was at least one patient with a streptococcal infection of the upper respiratory tract the causal organism could be recovered from the ward air, from the floor dust, and from the bedclothes throughout the infective period. During an epidemic of tonsillitis which occurred in January there were at one time nine cases in one ward. The dust obtained from this ward in one sweeping was estimated to contain over 100 million streptococci, and on one occasion nearly 70,000 of these organisms were suspended in the ward air (Fig. 2). The ward blankets that were examined contained between a half and one million streptococci each. Colonies from each test were typed, and the majority were found to correspond to the patients' infecting organism. A few other types were recovered (particularly Types XII and XXV and a Group G Lancefield strain), although no patient or member of the staff had such types in either throat or nose. As many as 30 to 50 streptococci could constantly be recovered on any plate from 10 c.ft. of ward air. We found this count to be regularly increased by bed-making or by any manœuvre which involved disturbing the bedclothes.

Similar counts were obtained in another ward, also with an outbreak of tonsillitis, when automatically exposed plates showed increases of aerial streptococci with the service of a meal, with bed-making, and, in particular, during visiting hours (Fig. 3). Again we recovered organisms of types different from those exhibited by the inhabitants of the wards, and this seems to be most probably accounted for by their persistence upon the bedding. Analysis of bedclothes again yielded up to a million streptococci per blanket.

The increase in aerial streptococci during bed-making was even more strikingly demonstrated in single-bed cubicles, in which there is less dilution owing to their smaller cubic capacity (Fig. 4). The highest count we recorded in a cubicle was 374 streptococci in 2 c.ft. of air. Counts of 150 to 200 have often been observed in these circumstances. Dust counts were higher in these cubicles than in the wards, probably because of a greater difficulty

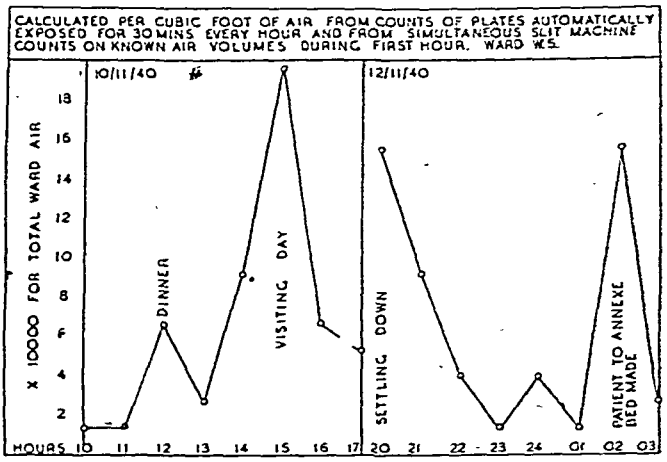

FIG. 3.—Streptococci in ward air

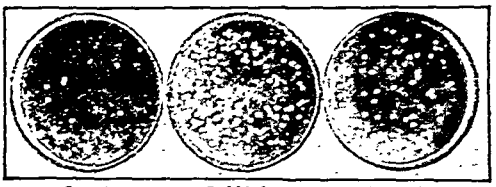

FIG. 4.—Aerial streptococci during bed-making.

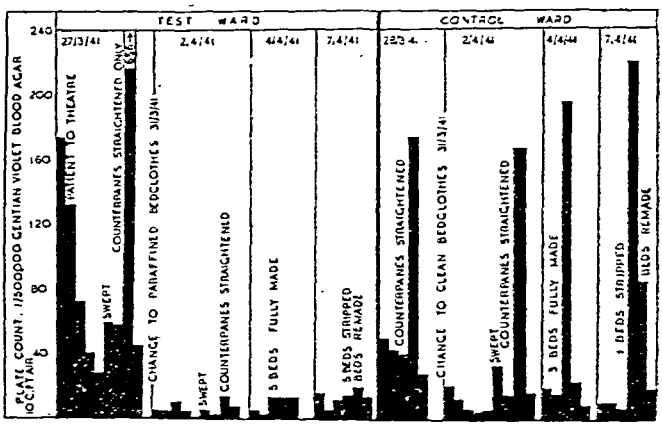

FIG. 5.—Reduction of aerial organisms by treatment of bedclothing.

in sweeping them thoroughly and because dilution of infected dust is less than in a ward. The dust of one cubicle, swept up in the morning, contained over 20 million streptococci per gramme, and the dust collected the same evening 5 millions per gramme. It is significant that these dust samples, when retested after a fortnight on the bench, showed very little reduction in the number of viable streptococci present, counts of 13 to 14 millions per gramme still

being obtained. Smaller numbers of streptococci were usually obtained in dust swept up from linoleum floors than in that from wooden floors, probably because the former can be swept more efficiently.

In one cubicle experiment the total number of organisms in 10 c.ft. of air rose from 15 to 1,528 as a result simply of straightening the counterpane and blankets of a single bed. Having regard to the reduction factor of our gentian-violet medium, this is equivalent to a dispersal of 2,500 organisms per cubic foot of air.

Ordinary bedclothes therefore represent such a powerful and persistent reservoir of infection that there is real danger of cross-infection from this source.

Reduction of Dust-borne Organisms in Air by Liquid Paraffin Treatment of Bedclothes

The experiments with paraffined bedclothing fall into three main groups: (a) experiments in which a whole ward was placed in treated bedding and another in clean bedding as a control; (b) experiments in cubicles in which a patient known to be emitting streptococci was transferred to paraffined bedding after a control period in ordinary bedding; and (c) the reverse experiment—changing such a patient into ordinary bedding after a control period in paraffined clothing. Ideally it is desirable to combine (b) and (c) with one patient, but this is rarely practicable: the patients soon cease to produce large numbers of organisms with adequate treatment, and an acute infective period of ten to fourteen days would be necessary for such an experiment.

(a) Ward Experiments

The ward experiments were made during a non-epidemic period, with most of the patients fully convalescent. The numbers of streptococci recovered were therefore small, and for the most part we have relied upon total counts as an index. In a preliminary control period we established that in both test and control wards there was a large increase in the number of organisms in the air with disturbance of bedclothes, even when this entailed only the straightening of counterpanes. At the end of this control period the beds in the test ward were supplied with paraffined bedding, while those in the control ward were given clean but untreated bedclothes. The men in the test ward were not told that their bedding was oiled, and at the time of the change were so used to the air-sampling machines running that they noticed nothing unusual.

Counts were made for periods up to eleven days. Some of the treated bedding was used continuously for more than a month, and when tested in cubicles had lost nothing of its efficiency. The increase in the bacterial content of the air associated with bed-making rapidly reappeared in the control ward, and, as was to be expected, became gradually greater. In the experiments shown diagrammatically in Fig. 5 the mean count during bed-making in the control ward was 194 organisms per plate. During the same period the test ward showed a mean count of less than 15, in spite of the fact that on each occasion five beds were made in the test ward as compared with three in the control ward. The use of paraffined bedclothing therefore reduced the number of organisms liberated during bed-making by 93% even in a large ward of sixteen beds.

(b) and (c) Cubicle Experiments

The results of one of the most striking experiments are shown in Fig. 6. The occupant of the cubicle developed a severe Type VI streptococcal tonsillitis during the January epidemic, and was transferred to clean bedding in a cubicle on the second day of his illness. The floor of the cubicle was not oiled, and the fact that two days after his transfer plates exposed during bed-making and sweeping grew 141 streptococci may partly be due to this. The floor dust collected that morning was estimated to contain over 13 million streptococci per gramme, and a further 4,900,000 per gramme had accumulated by the evening. From

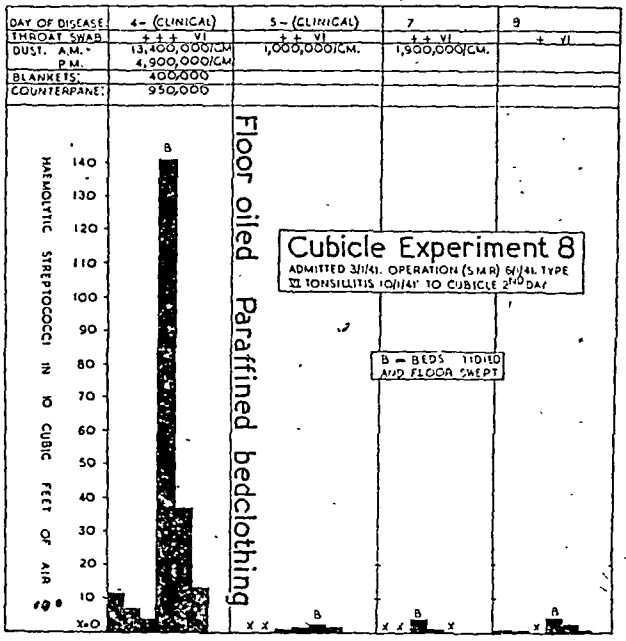

FIG. 6.

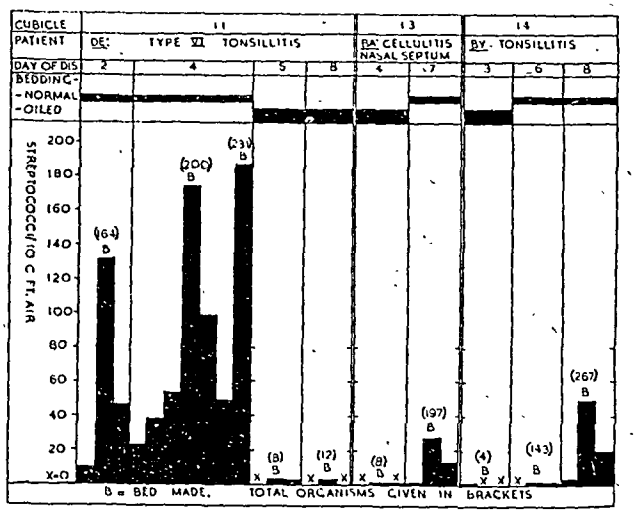

FIG. 7.—Reduction of aerial streptococci by paraffined bedclothing.

samples taken from his bedclothes it was calculated that in this period of forty-eight hours his blankets had collected 400,000 streptococci each, while the counterpane contained nearly a million of these organisms. On that day the floor was oiled and he was changed into paraffined bedclothes. This resulted in a striking fall in the numbers of streptococci projected into the air, the mean count up to the eighth day being less than 4 organisms per plate, in spite of quite vigorous bed-making. That he was emitting streptococci during this period was shown by analyses of floor dust, which contained a million streptococci per gramme on the day after the change and nearly 2 millions per gramme two days later.

A similar, and equally striking, experiment is shown in Fig. 7 (cubicle 11). In this case the floor had been oiled for some months, and at the time of this experiment the

or treatment was still effective. Control experiments up the sixth day of the disease showed that 130 to 180 ptococci could be recoveted from 10 c.ft. of air during d-making, and it is significant that two such peaks a be produced within thirty minutes of each other. A ange to paraffined bedclothing led to an immediate fall th of total organisms and of haemolytic streptococci by re than 95%. Throughout this period the patient had luxuriant growth of streptococci in his throat.

The reversed experiments are equally illuminating (Fig cubicles 13 and 14). Here two men, one with a ere cellulitis of the nasal septum and the other with acute follicular tonsillitis, were placed direct in paraffined dclothing for four and three days respectively. This iod is sufficient to allow large numbers of streptococci accumulate on the bedclothes. At the end of this period was only by hard shaking of the bedclothes that we re able to grow a single streptococcus from the air. ese patients were then changed to ordinary bedclothes, ich immediately began to liberate considerable numbers streptococci whenever the beds were made.

The experiments have shown, therefore, that the treatnt of bedclothes with a dust-laying oil greatly reduces e number of organisms which can be liberated from them. e think it significant that its use, in the same degree the use of spindle oil on floors, has never yet failed to lace the swarms of bacteria, both pathogens and saprotes, which are showered into the air whenever a bed made or a blanket moved.

Discussion

That dust may be responsible for cross-infections has en known for many years (Flügge, 1897; Neisser, 1898; instein, 1902), but the importance of these earlier observans seems to have been neglected in succeeding decades. terest in the infectivity of dust has more recently been vived, and cases have been reported in which cross-fection has undoubtedly been due to dust. The presence streptococci in ward dust has been shown by Deicher 937); Allison and Brown (1937); Cruickshank and ober (1939); Glass (1941). The importance of dust the spread of respiratory infections in hospital wards s, however, not received general recognition, and little tempt has been made to guard against the danger of dust-rne infection.

Ward dust comes from two main sources—floors and dclothes—and from these it is distributed into the air sweeping or by bed-making (Cruickshank, 1941; Miles d others, 1940). Dust on the floor is readily made relaely innocuous by treatment with a dust-laying oil, a ct which has long been known, but has not been adopted hospitals until recently. The treatment of floors with dust-laying oil prevents the organisms deposited on them om being distributed into the air. Bacteria are not stroyed by the oil, and the dust swept up must therefe still be treated as infective and disposed of suitably.

Bedclothes constitute an equally if not a more serious urce of aerial contamination. Streptococci accumulate pon the bedclothes of any patient with a streptococcal fection of the upper respiratory tract. Deicher could cover streptococci from the walls and furnishings of scarlet ver wards. Glass has obtained similar results in puerperal ver wards, and in the wards in which our experiments ere performed it was possible to recover streptococci even om the ceilings. Hare (1941) showed that the accumuation of streptococci could occur also in the environment healthy streptococcus carriers. The rate at which streptococci accumulate is of importance. With cases of cute follicular tonsillitis placed in clean bedding we have ten able to demonstrate an accumulation of nearly a illion streptococci in a single blanket in two days.

Although the bedding from such cases is normally disinfected, the same does not hold for every patient who develops a sore throat in hospital. Ward blankets, unless obviously dirty, are only too often used over and over again. The same holds for blankets on theatre trolleys. The risk of spreading infection by this means is only too obvious. Blanket dust is one of the main sources of air-borne streptococci in hospital wards; and may play an important part in air-borne cross-infection. The simple act of making a bed may throw into the air as many as 2,500 organisms per cubic foot, and it is common, in infectious wards, for blankets to contain anything from a half to one million streptococci each. We have shown that on occasion as many as 70,000 streptococci may be freely suspended in still ward air, and that even in a large ward, where considerable dilution must occur, this number is doubled or trebled when a bed is made. In smaller wards the rise is proportionately greater, and a tenfold increase is not uncommon. Cruickshank found 200 streptococci deposited upon a pair of Petri dishes in an hour during bed-making and toilet. This would correspond to a recovery of 2,500 streptococci by a slit-machine or 40 per cubic foot of air. These counts are of the same order as we observed in our single-bed cubicle experiment. A patient in such a cubicle may therefore be inhaling between 500 and 1,000 streptococci an hour, of which 90% would have been retained within the respiratory tract (Lehmann, Saito, and Gfrörer, 1911). We do not know what number of organisms constitute an infective dose, but there can be no doubt that in a ward in which no precautions are taken against dust the risk of respiratory infection is very great.

These experiments have shown, further, that during bed-making the number of organisms liberated from bedclothes is reduced by 90 to 95% by treating them with liquid paraffin. This reduction, which occurs both in large wards and in small isolation cubicles, is of the same order as that found by van den Ende, Edward, and Lush in their laboratory experiments. As in the dust of oiled floors, the organisms on oiled blankets, although prevented from being distributed into the air, are still viable and potentially pathogenic.

The application of liquid paraffin from a solution in white spirit requires specially designed hydro-extractors, with an automatic return of the liquor direct to the soaking-tanks, which are not available in hospital laundries. Moreover, the use of white spirit as a solvent involves special fire precautions. In these experiments we were concerned, however, only with establishing the efficacy of the principle involving the application of dust-laying oils on bedclothes. Experiments with simple oil-water emulsions applied in the form of a spray, and with oils other than pure medicinal paraffin, are at present in progress.

Dust-laying methods can, of course, only be expected to be effective against the spread of infection when the patients are confined to bed. They cannot prevent direct infection among ambulant patients, with whom droplet infection probably plays the major part, or in cases in which infection is spread by other means than through the air. It seems essential, therefore, that all hospital patients exhibiting β-haemolytic streptococci in their throats should be confined to bed. If this is done the combination of the method of laying dust on bedclothes with the use of spindle oil on ward floors will greatly assist in reducing the incidence of ward infections. It will probably find special application in scarlet fever, diphtheria, and ear, nose, and throat wards.

Other sources of dust, though probably less important, should not be neglected. Thus damp dusting or dusting with oil-impregnated dusters is essential, and the possibility that streptococci may be carried upon the clothing of doctors, nurses, and ward orderlies must be considered.

These points require further investigation, and it is now necessary to undertake experiments on a large scale, to determine whether a continuance of all available methods of dust-laying will result in a significant reduction of the incidence of cross-infections in hospital wards.

Summary

Attention is drawn to the very large numbers of streptococci which may accumulate in the dust and in the bedclothes of hospital wards.

It is shown that many of these organisms are projected into the air every time a bed is made or in any way disturbed, and it is suggested that these represent a very real danger.

The treatment of bedclothes with liquid paraffin, while not visibly affecting them, causes a 95% reduction in the number of organisms distributed into the air during bed-making.

It is suggested that this method of dust-laying, combined with the use of spindle oil on floors, may assist in reducing the incidence of cross-infections in hospital wards..

We are indebted to Major-Gen. H. Marrian Perry, C.B., O.B.E., F.R.C.P., Director of Pathology, Army Medical Services, for allowing one of us to carry out his part of this work in a military laboratory; to Colonel E. B. Marsh, *M.C.*, R.A.M.C., for placing so many facilities at our disposal; to Dr. C. H. Andrewes, F.R.S., and Dr. R. B. Bourdillon for much helpful advice; to Dr. Otho Fitzgerald, medical superintendent of the hospital, for the use of the hospital laundry; to the medical officers and nursing staff who have co-operated so readily with us; and to our assistants, Sergt. H. G. Stevens, R.A.M.C., and Cpl. T. Bury, R.A.M.C., for their continued help in the laboratory.

It was recently announced by the Board of Trade that arrangements had been completed for the manufacture of an adequate supply of high-tension batteries to meet the needs of deaf persons who use hearing aids. A standard range of batteries to be manufactured in wartime has been drawn up and embodied in a specification to be issued by the British Standards Institution (B.S. 966) High-tension batteries for hearing aids must be as small in size and as light in weight as possible, and in peacetime these requirements were met by making up the batteries from very small unit cells. At the present time there are heavy demands for these midget cells for batteries for other purposes, and it has become necessary to standardize a range of batteries for hearing aids made up from cells which, so far as can be seen at present, will be available in sufficient quantity to enable hearing aids to continue to be serviced with the minimum of inconvenience to all concerned. There are eleven batteries in the standard range, and these should prove adequate to cover the requirements of all existing makes of hearing aids which employ H.T. batteries, though it may be found that some instruments will need minor modification in order to accommodate them. Such modification applies to the battery casing only, and no modification to the mechanism of any instrument is called for. Copies of this new specification will be available shortly from the British Standards Institution, 28, Victoria Street, S.W.1, price 2s. 3d. post free.

RECENT EXPERIENCES IN THE TREATMENT OF GONORRHOEA IN THE MALE*

BY

R. M. B. MacKENNA, M.A., M.D., F.R.C.P.

Major, R.A.M.C.; Command Specialist in Dermatology, Northern Command

In military practice the incidence of venereal disease is surprisingly low, and in this I have no doubt that we are reaping the benefit not only of the far-sighted policy of the Ministry of Health, but also of the standard of work which medical officers in charge of clinics have maintained during the past twenty years. The Medical Services of the Army also deserve much credit. For many years the officers of the Royal Army Medical Corps have insisted on educating the troops for whose health they are responsible on the dangers of promiscuous intercourse; as is widely known, their preventive work in the venereal field has reached a very high standard. In the active treatment of venereal diseases their standards have been equally high, and the population at large owes a debt to the Army Medical Services which, while unrecognized by the majority—venereal disease not being a subject for public discussion—is nevertheless very real. Despite the disturbances of war the Medical Services have taken steps to ensure that the prevention of venereal diseases and the treatment of these diseases are in keeping with modern standards.

Experiences in the Use of Sulphapyridine

We have found that the local application of sulphapyridine to chancroidal ulcers is a satisfactory form of treatment.

Some of our experiences in the treatment of gonorrhoea with sulphapyridine may be of interest to the profession. At the outset I wish to emphasize that I here refer to practical work. A war is in progress, and it is our duty to get the men fit and back to their units as soon as possible. For this reason the necessarily slow methods of pure clinical research have not been possible; but our work is controlled by a system of surveillance after the patients leave hospital, and we are able to assess from this, with a great degree of accuracy, whether our belief in the methods of treatment we use is based on mere optimism or on therapeutic achievement. The fact that this surveillance is usually carried out by medical officers in districts remote from ours makes this form of control of our work more satisfactory and perhaps less liable to criticism than otherwise it might be. I will refer to this subject later in the paper.

When, a little over a year ago, I took over my duties as officer in charge of a dermatological division, the cases of gonorrhoea were being treated on routine lines. Sulphapyridine was administered thrice daily, the average dosage being 3 grammes a day. Treatment was given for a week or ten days, during which time the men were kept in bed and on a light diet The results were satisfactory, but not outstandingly so.

As you probably know, in the Army cases of gonorrhoea are treated in hospital and the men are not allowed to carry on with their duties. This confinement to hospital may be irksome to the individual, but from the medical standpoint it is of the greatest benefit both to the patient and to the physician. I soon came to the conclusion that with the

* Being part of an address delivered to the North of England Branch of the British Medical Association at Newcastle-upon-Tyne, October 31, 1940.

atients under observation and their diet under control ery much larger doses of sulphapyridine could safely be iven. I therefore instituted an "eight-day course," during hich the men were strictly confined to bed, received only nilk diet, and were encouraged to drink as much barley-ater as they could stomach. The course of treatment as as follows: On the first day they received 6 grammes f sulphapyridine. This dose was repeated on the second lay; on the third and fourth days they were given l grammes daily, and on the remaining days 3 grammes The tablets were given thrice daily, and the course consisted of 32 grammes of sulphapyridine in eight days. omewhat to my surprise there was no difficulty in keeping he men on milk diet for that length of time. As one philosopher sadly remarked: "Those d——n tablets makes ou feel so lousy you doesn't want to eat."

On this course, which was given to several hundred cases, here were no severe complications, but there was too high a proportion of generalized scarlatiniform eruptions associated with a brisk rise of temperature. This complication usually developed between the seventh and the tenth days (usually the ninth) after the course began. It caused the patient some discomfort, but, as the rash and the fever seldom lasted longer than forty-eight hours, it did not give us much anxiety. For the majority of the patients the chief disadvantage of the treatment was that when on the ninth day they had to get up they were weak from the combined effects of the action of the drug and the low diet. Nevertheless the method was successful and relapses were few.

After this routine had been employed for some months I asked Major R. T. Wordingham to concentrate on the treatment of gonorrhoea in my department, and to alter and amend the method as he thought fit. We had the benefit of a consultation with Dr. R. Forgan, who told us that in his opinion it was the initial heavy dose of sulphapyridine which was the essential factor in curing the disease. We kept this opinion in mind, and Wordingham began his investigations.

Requirements in Sulphapyridine Treatment

We agreed that in sulphapyridine treatment there are certain desiderata. These may be tabulated as follows:

1. That the first dose should be the maximum which the average patient would tolerate.

2. That it was a mistake to administer the drug only during the day. The administration should be maintained throughout the whole of the twenty-four hours so as to keep the concentration in the blood as high as possible.

3. That the patients should be kept on milk diet during the course of treatment. We were, and still are, convinced that this is beneficial.

4. That barley-water should always be available in the wards, and that the patients should be encouraged to drink as much of it as possible.

5. That particular care should be taken to avoid constipation. We had noticed that the scarlatiniform eruption due to sulphapyridine was invariably preceded by constipation for forty-eight hours or longer. There is no doubt that failure to defaecate is an important predisposing factor in the development of the complications of sulphapyridine therapy.

Wordingham's first task was to discover the optimum initial dose of the drug and to curtail the length of the course. This necessitated a long series of clinical observations and some biochemical investigations. During these he discovered two things: first, that if the patients are not allowed to smoke, nausea and vomiting—those two bugbears of this form of treatment—are reduced; secondly, that the administration of potassium citrate in large doses (30 grains in a simple mixture, two-hourly) is beneficial. By a process of trial and error Wordingham devised a routine which we have used in many hundreds of cases, and during this time we have had only one death. This case, examined at necropsy by an independent pathologist, was found definitely not to be due to sulphapyridine poisoning. The findings of the pathologist, with notes on the case, were submitted to Lieut.-Colonel T. E. Osmond, R.A.M.C., who agreed that death could not be attributed to the drug.

The course consists in the administration of 22 grammes of sulphapyridine in forty-eight hours. The tablets are crushed and are given in milk every four hours during the day and night. Two important points should be noted—namely, that the tablets are *crushed*, and that there is no interruption of the treatment during the night. The first dose is 5 grammes; the second, 4 grammes; the third, 3 grammes; the fourth, 2 grammes; the remaining eight doses are each of 1 gramme. If a patient begins treatment at noon he will be given 10 crushed tablets (each tablet of sulphapyridine containing 0·5 gramme): at 4 p.m. he receives 8 tablets, and at 8 p.m. 6 tablets. At midnight he is awakened and given 4 tablets, and at 4 a.m. he has 2 tablets. And so the course continues until he has received the total dose of 22 grammes.

The course differs considerably from the routine treatment, devised by Lieut.-Colonel T. E. Osmond, R.A.M.C., which is generally used in the Army. That treatment is as follows: On the first day the patient receives 2 grammes of sulphapyridine as soon as the disease is diagnosed, and thereafter 0.5 gramme every four hours during the day and 2 grammes at bedtime. On the second day he receives a total of 4 grammes of sulphapyridine, and from the third to the seventh day, inclusive, 3 grammes of the drug every day. Irrigation of the urethra with potassium permanganate or oxycyanide of mercury may be used in conjunction with the sulphonamide therapy, at the discretion of the medical officer. This treatment is followed by the usual investigations of the prostate gland, etc.

Lieut.-Colonel Osmond, to whom we are much indebted, gave us the benefit of his opinion both by writing and verbally. Wordingham's intensive course was adopted only after consultation with him and with his concurrence.

During the intensive course of sulphapyridine most of the patients have some degree of frontal headache; about 10% suffer from sickness; and many show a slight degree of cyanosis, but this disappears within twenty-four hours of the termination of the course. The cyanosis is little more than a slight blueness of the lips, and, in some men, a very slight degree of slate-blue discoloration of the face and ears. In this respect Buttle (1939) may be quoted: "Cyanosis seems to be partly due to the elaboration of pigments from condensation of the drug itself, and it is usually thought that it can be neglected from consideration as a symptom of overdose."

Vomiting is a variable factor. If it occurs it usually develops about eighteen hours after starting treatment—that is, about two hours after the taking of the fifth dose. Thereafter the patient may not vomit again, or if he vomits he will do so an hour or two after each administration of the tablets. The wastage by vomiting is therefore not great. At the present time we are having a series of biochemical investigations carried out to determine the average loss of the drug in those patients who vomit. So far as our investigation has gone the actual loss appears to be very small; this confirms the clinical findings, for we have not experienced any marked delay in response to treatment in those cases in which vomiting has occurred. Vomiting is, of course, influenced by psychological factors. If two or three men in a ward vomit, the majority of their companions will follow their example. If before the course begins they are warned that they may be sick, they usually are sick.

Complications of Sulphapyridine Therapy

Headache, lassitude, nausea, and vomiting are the only complications which we anticipate. We have not seen a case of agranulocytosis or of haemolytic anaemia.

There are, however, two complications which are seen and which must be remembered. In a few cases during the course of treatment, and usually early in the second day, the patient may complain of pain in the lumbo-costal area, extending thence to the epigastric region. Usually it is felt on only one side of the body, but it may be bilateral. The pain is severe and the patient may be restless. There is marked tenderness on deep palpation of the upper lumbar area, and there may be tenderness on pressure over the ureter. Occasionally before the pain develops, but as a rule shortly after, the patient's urine becomes blood-stained, and a brisk haematuria may occur. In severe cases there is usually a visible precipitate of crystals if the urine is allowed to stand in a conical urine glass. When these symptoms develop there is a diminution in the amount of urine passed, with nitrogen retention. Vomiting usually occurs, and may be severe. We regard the condition as a pyelonephritis caused by the formation of a compound known as acetyl-sulphapyridine. The crystals of this compound take the form of sharp needles, and we presume that the haematuria is produced in a manner analogous to the bleeding in oxaluria.

In most cases there are no further signs or symptoms, but in a few instances anuria occurs, and may persist for as long as thirty-six to forty hours. During this time no grave symptoms have developed in the cases we have had, but, needless to say, the condition is one which we have viewed with some anxiety.

The treatment given has been simple but successful. The administration of sulphapyridine is stopped; the pain is relieved by 1/3 grain of morphine; barley-water is given in large amounts; and the administration of potassium citrate is continued. If vomiting is troublesome rectal salines are given so that the maximum fluid intake is obtained. Constipation is treated by cascara and, if necessary, by enemata. Here I should like again to emphasize the importance of avoiding constipation during sulphapyridine therapy: in almost all these cases the bowels have not been open for two or three days before the appearance of the symptoms. The pain and haematuria usually disappear within forty-eight to sixty hours of their onset, and as a rule the gonorrhoea is cured. I have not had an opportunity to work out the exact incidence of this complication, but it does not occur in more than 1 in 600 cases.

It may be asked what permanent effects accrue as a result of these events. Needless to say we have watched with particular interest the men who have suffered in this way. In no case have any signs of permanent renal damage been found. Ten days after the haematuria has disappeared the urine has been clear: there has been no albuminuria, and casts and red blood cells have not been demonstrated in centrifugal specimens. Also the blood urea has been normal, and urea-concentration tests have given no evidence of impaired renal function. These tests, repeated after an interval of three or four months, have produced similar satisfactory results.

Recently doubt has been cast on the belief that saline purgatives should not be given during the administration of sulphonamide compounds. Forgan (1939) has said that "it might be proved that there was no advantage, possibly even a disadvantage, in eliminating foods with a high sulphur content from the diet of patients receiving moderate doses of sulphapyridine (M & B 693)." With regard to these two points we have known cases in which, despite instructions to the contrary, some patients have taken magnesium sulphate in fairly large doses whilst receiving sulphapyridine, and others have had eggs and onions while taking sulphanilamide. In no case have we noted any ill effects from these departures from the customary regime.

I have described in some detail Wordingham's course of sulphapyridine therapy because I am convinced that, provided the patient has an average tolerance to the drug, the ideal line is to attack with a maximum dose and to give a short course of treatment. This method succeeds where other methods fail, as in the case (referred to at page 982 of this issue) of the young officer suffering from chronic meningococcal septicaemia, who was not cured by small doses of sulphapyridine, but who rapidly responded to the short intensive course. Quite rightly it may be said that in the Army we are dealing with young men chosen after a medical examination, and we cannot presume that this method of treatment would be so successful if applied to the community at large. We appreciate this, but we have noted that older men in the fourth decade have usually tolerated the course well. Social distinctions sometimes make a difference in therapeutics, and particularly in gonorrhoea, from which the average hospital patient seems often to make better recovery than the private patient; but we have had no complications or difficulties arising in those officers whom we have treated.

There is one obvious precaution on which we do insist: we consider it inadvisable to administer the treatment to patients who have a history suggesting that they may have suffered from gastric or duodenal ulcer, for in these cases there is a risk that severe vomiting may develop and haematemesis may ensue.

The Routine followed by Gonorrhoea Treatment

It must not be imagined that the treatment of gonorrhoea in my department is confined to the administration of sulphapyridine. The full routine is as follows:

As soon as possible after the diagnosis has been confirmed by microscopical examination of the urethral discharge the patient is put to bed. If he is considered to be a suitable subject for intensive therapy he is given a milk diet, and mist. potassii citratis and barley-water as already indicated. He receives 22 grammes of sulphapyridine in forty-eight hours. On the third day he gets up. He is usually a little weak and lethargic, but is quite fit to take his meals in the dining-room and to go to the irrigation room for treatment. Usually his urethral discharge has almost ceased, but there may be a slight muco-purulent urethritis. On microscopical examination of this discharge pus cells and epithelial cells may be found, but gonococci can seldom be demonstrated. He is then kept for two or three days on irrigations of potassium permanganate 1 in 8,000, or oxycyanide of mercury of the same strength. Treatment is given thrice daily and the "grand lavage" is used, the irrigating fluid being allowed to flow into the bladder. On the sixth day the patient, who has not urinated for at least eight hours, reports at 6.30 a.m. for a "morning urethral smear." Very often a smear is not obtainable. If there is any moisture in the meatus it is usually found on microscopical examination to consist of mucoid secretions, probably prostatic in origin, with a few epithelial cells and spermatozoa. Later in the day a two-glass urine test is made, and if this is satisfactory a prostatic smear is taken. Usually no evidence of prostatic infection is found.

If these tests are favourable the patient takes two bottles of stout with his evening meal, for alcohol is a good test of cure. The "morning smear" and the urine examination are repeated on the seventh day, and if these are satisfactory a provocative dose of gonococcal vaccine containing three hundred million gonococci is given. On the eighth day the patient reports for yet another "morning smear"; a prostatic smear is taken and the usual urine test is made. If these tests are all satisfactory the anterior urethra is examined through a urethroscope. At this stage we expect to find a diffuse reddening of the urethra, but no littritis—no inflamed follicles. A curved sound of suit-

able size is passed. If possible we keep the patient under observation for a further two days, as occasionally there is a delayed reaction to the vaccine.

You will note the frequency with which the "morning smear" is investigated, and the fact that every patient has at least two prostatic examinations. This is because we are well aware that one of the dangers of sulphapyridine therapy is that in some cases pus formation, the cardinal sign of gonorrhoea, is decreased, while gonococci may occasionally be present in the urethra or in the prostatic secretion.

When our tests of cure and the period of observation are finished the patient returns to duty, but observation on the case does not end. Three weeks later the man reports to a military hospital, where he is examined by a medical officer who has had a training in the treatment of venereal disease. He is examined for signs of urethral discharge; the two-glass urine test is made, a prostatic smear is taken, and usually a curved sound is passed. The same investigation is repeated during the following two weeks. Although all the tests may be negative (and if they are not he is immediately referred back to us for treatment) he is not yet passed as cured. Three months after his discharge from hospital he is sent either to us or to some other centre. Another provocative injection of gonococcal vaccine is given, and all the usual tests—macroscopic, microscopical, and urethroscopic—are carried out. Only if these are negative is he discharged as cured. During the period of surveillance Wassermann tests are carried out to ensure that a concomitant infection with syphilis has not been missed.

I think, therefore, that we can claim that our work, though purely clinical, is well controlled: this being so, it is satisfactory to find that the relapse rate is under 5%

Summary

The incidence of venereal disease is discussed, together with the part played by the Medical Services of the Army in prevention.

An intensive method of treating gonorrhoea is described at some length.

ACUTE GONORRHOEA

FURTHER OBSERVATIONS ON TREATMENT BY SULPHAPYRIDINE FOLLOWED BY LAVAGE

BY

JAMES SOMMERVILLE, M.B., Ch.B.

Clinical Medical Officer, Bellahouston Venereal Diseases Centre and Southern General Hospital, Glasgow

In my original article (Sommerville, 1939) I reviewed 152 consecutive cases of acute gonorrhoea treated with sulphapyridine alone, without adjuvant therapy, in 90% of which early cures without complications were obtained. By comparison Dr. J. G. McGregor-Robertson (1938), using the drug in connection with lavage, claimed 100% early cures, but with 3% complications.

Technique

In a final note to that article I stated that I had altered my technique. This alteration was made in an attempt to maintain the freedom from complications and at the same time to improve the percentage of early cures. The present article is a review of 300 consecutive cases treated according to the new technique, which is as follows.

Sulphapyridine is given, the dosage being 0.5 gramme (one tablet) four times a day for one week. Irrespective of the clinical results at the end of this period, irrigation with 1 in 8000 potassium permanganate daily is instituted for a week, followed by similar lavage on alternate days for another week. In most cases this completes the treatment, but if the clinical and urinary examinations are not entirely satisfactory at the end of three weeks lavage is persisted with until the desired result is obtained. Thereafter observation for three weeks is maintained, and a prostatic smear is then taken: if this is satisfactory (less than four pus cells per field) urethroscopic examination, followed by the passing of a curved bougie, is carried out a week later. If there is no response to instrumentation a routine Kahn test is done the following week; and finally all being well, the patient is discharged at the end of nine weeks.

It is now fairly well established that if sulphapyridine is going to act satisfactorily, as it does in 90% of cases, it will do so in approximately three days. If a urethral discharge of any type exists after a week I believe that the virulence of the gonococcus is so diminished that any danger of complication arising as a result of irrigation is at a minimum

Survey of Results in 300 Cases

The results obtained from the present series serve to prove my contention that large doses of the drug are not necessary, and that practically 100% of early cures can be obtained with almost the same percentage of freedom from complications. This article is published not simply because I think the results are satisfactory but more especially as a plea for economy in the use of the drug and with all due deference to those who believe in and employ massive or intensive dosage

In going over the case records I find that my original enthusiasm in investigating the time interval required for urethral smears to become gonococcus-negative has waned considerably, and such observations were noted in 103 cases only. The average time interval in these was 1.74 days, compared with 1.92 days in my original series.

For the purpose of "dry" observations 9 cases are excluded from the record of figure averages. Of these 9 patients 7 were irregular attenders and, later, defaulters with no dry observations of any value owing to the time intervals in their attendance, 1 (a chronic persistent alcoholic who defaulted after nineteen days) failed to clear up or even improve, and 1 (one of two cases which showed repeated relapse, and the subject hereafter of a special note) relapsed before a completely dry observation could be obtained. I have divided the remaining 291 into four groups, as shown in Table I.

TABLE I

Type	No. of Cases	Urethra Dry-Day Average
Average case	250	4.98
Avowed alcoholics	33	23.09
Admitted re-exposures	5	25.60
Complications before therapy	3	30.00
Total	291	7.66

This division has been made because there is such a marked discrepancy between the figures of the normal average case and the other three groups. Especially interesting is the alcoholic group. The intake of alcohol quite evidently makes a considerable difference in the prognosis of a case, as the figures prove. It is also scarcely fair to slump all the cases together and thus alter materially the statistics obtained. The results obtained in the present series conform very closely to those of my previous one. Thus from the figures already given it can be seen that out of 293 cases 2 (0.68%) may be recorded as failures.

I have once more investigated the question of intolerance, so as to arrive at a more or less accurate estimate of any toxic upset with the moderate dosage employed. Of the 300 cases 39 (13%) gave some sign of intolerance, 9 of them having two symptoms. Table II shows the incidence of each upset.

TABLE II

Kind of Upset	No.	Average Day Incidence
Nausea	14	2.85
Temperature	1	3 (? influenza)
Headache	14	3.85
Indigestion	5	4
Vomiting	7	4
Cyanosis	2	5
Vertigo	4	6
Rash	1	7

Table III shows the incidence of complications noted before and after starting treatment: 10 (3.33%) were recorded before and 5 (1.66%) after therapy began.

TABLE III.—*Complications*

Type of Complication	Before Treatment	After Treatment	Explanation of Complications Noted After Treatment
Prostatitis	6	2	1: alcohol ++ 1: wife G.C. + 1: prostatitis before 1: re-exposed
Epididymitis	3	2	
Prostatitis + epididymitis	1	—	
Periurethral infiltration	—	1	
Total	10	5	

Relapse was noted in 20 (6.66%) of the cases reviewed, no history of re-exposure or fresh infection being admitted. Alcoholism accounted for 15, and this was denied in the remaining 5. Of these 5 patients 2, including the case already mentioned, gave a history of repeated relapse, and constantly denied sexual excitement, re-exposure, or alcoholism. The remaining 3 cases gave no history of alcoholism either before or after the onset of the disease, and are therefore more likely to be examples of genuine failure to respond to the drug. They subsequently cleared up, however, with additional treatment. Of all the cases of relapse 10 subsequently cleared up completely and were discharged well, 9 defaulted, and 1 was transferred to another centre.

I am afraid that I very gravely doubt the veracity of the statements of many patients attending at V.D. centres. I have often been given a denial as regards intake of alcohol, which was later corrected after a lapse of time, when the patient had forgotten what he had told me. *Omnis syphiliticus mendax est* is as true to-day as it ever was, and every dodge and trick must be employed to elicit the truth. The failure of all my wiles to break down repeated denials of alcohol or re-exposure, and the protestations, with every appearance of injured innocence, in two cases of repeated relapse worried me not a little.

These two cases proved so troublesome—and ultimately interesting—that they merit a note by themselves. In both cases, to begin with, alcoholism was admitted at the first examination, but thereafter alcohol, re-exposure, and sexual excitement were consistently denied. No sign of any complication could be found in spite of full and persevering clinical examination for any residual focus. Even before they were ultimately and finally dismissed as cured an appeal to "honour in the cause of science," an appeal which I have often found effective in getting the truth, failed completely, so that I was left with an uneasy and unhappy feeling about the mystery of it all. Both cases had had chemotherapy and lavage, repeated at intervals, and also vaccine therapy. The result was always the same—a quick response to treatment, complete freedom from symptoms for two to three weeks, and then a breakdown to "purulent" again.

While going over the records and preparing my figures I was struck by the comparative regularity of those repeated relapses; so with the aid of a calendar I checked up on the day of the week that each clinical note of "purulent" was made. To my astonishment, and I must admit relief, the incidence of relapse fell on a Monday, except for a few occasions when it fell on a Thursday—that is, forty-eight hours after a Saturday or Tuesday holiday. My own conclusion, although another interpretation may be possible, is that both men had succumbed to temptation and had lied consistently. I presume that the repeated questioning, with the obvious suspicion that I simply did not believe them, and ultimately an increasingly poor prognosis being hinted at, must have scared them sufficiently off alcohol to enable a cure to be finally obtained. Table IV shows the incidence of relapse, the above 2 cases being excluded.

TABLE IV

	No.	Time of Relapse in Days					
		1-7	14	21	28	35	56
Alcohol	15	2	3	2	3	4	1
No apparent cause	3	-	1	1	1	-	-
Total	18	2	4	3	4	4	1

Conclusions

These follow-up investigations confirm the efficacy of sulphapyridine as a cure for gonorrhoea. Moderate dosage—namely, 0.5 gramme four times a day—has continued to give excellent results, and intolerance with this dosage is not pronounced. The use of subsequent irrigation has increased the early cures to practically 100%, with almost the same percentage of absence of complications.

Summary

Review is made of 300 consecutive cases of acute gonorrhoea treated with sulphapyridine, 0.5 gramme four times daily for one week, followed by two weeks' lavage.

Only 2 (0.68%) patients failed to show the usual early clinical cure: one an avowed alcoholic and defaulter; the other, with a subsequent history of repeated relapses, almost certainly an alcoholic.

The course of the disease in alcoholics, in those re-exposed, and in those presenting complications before treatment is contrasted with the average normal case.

Toxic symptoms were noted in 13% of cases, none of them serious.

Complications arising after treatment was begun occurred in 5 (1.66%) cases, but in 4 of them an exciting cause is demonstrable. In only 1 (0.33%) case can the drug be said to have failed to prevent a complication.

Relapse occurred in 20 (6.66%) cases, alcoholism being admitted in 15 and being present almost certainly in 2 others. In 3 (1%) cases relapse occurred for no apparent reason.

Dr. F. M. Turnbull (*J. Amer. med. Ass.*, 1941, 116, 1809) treated cases of chronic sinusitis by spraying the nasal passages with a 5% solution of the sodium salt of sulphathiazole. He states that considerable relief was attained in 40 out of 47 patients. He observes that cultures taken from the sinus have shown that the predominating organism is the staphylococcus.

SURGICAL TREATMENT OF CONGENITAL PYLORIC STENOSIS

BY

DAVID LEVI, M.S., F.R.C.S.

Senior Surgeon, Infants Hospital, Westminster, S.W.; Surgeon to an E.M.S. Hospital

The uncertainties of the time in which we live, the possibility that all records may be destroyed, have prompted me to publish the figures and tables reproduced below. They appear to me to be of value in that they demonstrate the striking difference in the mortality of pyloric stenosis in breast-fed and bottle fed infants. This fact has been recognized, but herewith it is very clearly demonstrated.

Table I is a list of 100 breast fed babies operated on at the Infants Hospital, Westminster. It is a consecutive list of the breast-fed infants either referred to me by my medical colleagues or admitted under my charge during the period reviewed. No child was ever refused operation, as no child suffering from this disease is ever too ill for operation. There were no deaths. All the children were discharged from hospital well. There were 13 girls and 87 boys. Four children did not have their birth weight recorded. Of the remaining 96, 48 were below birth weight when operated upon.

Table I shows that the earlier patients were kept in hospital longer than the later ones. The length of stay is a matter of grave import in treating sick babies, but it does not appear to be such a decisive factor in breast-fed children, provided that mother and child are both resident in the hospital. In the earlier part of the list—1 to 50—many of the patients were kept for days before operation. Latterly, the length of stay in hospital has tended to decrease. Most of the patients were admitted under the charge of a physician, and the duration of the period of premedication varied with the practice of the particular physician under whose care the child was placed. Patients admitted direct to my beds have been treated as emergencies, and have been operated on immediately, without any preliminary treatment other than a gastric lavage. One has been agreeably surprised at the good progress these children have made (Charts I, II and III).

The result in this series of breast-fed infants is 100% cure. Moreover, the cure is speedy, safe, and certain. The outlook seems to be even more helpful than that of most surgical operations, since the anaesthetic risk has been not only eliminated. The same story, however, does not hold good for the bottle-fed infants. In 1938 23 children were operated on and 2 were lost.

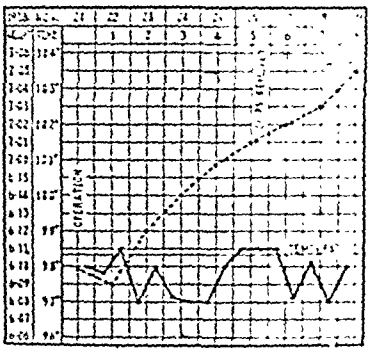

CHART I

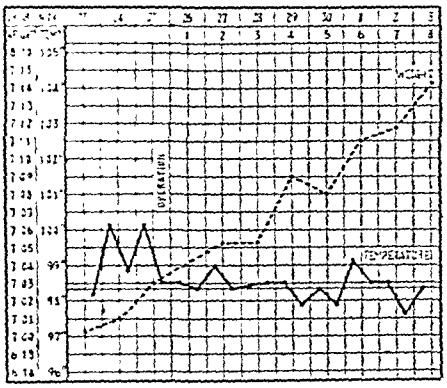

CHART III

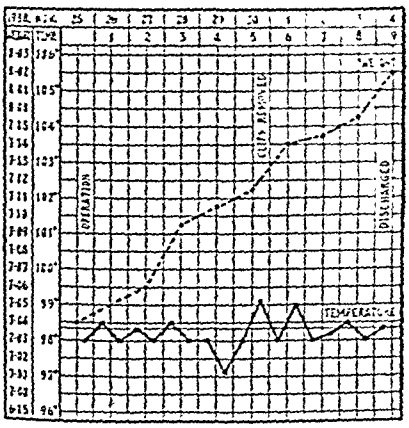

CHART II

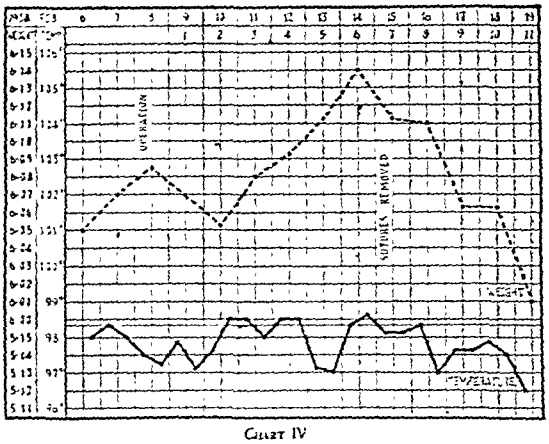

CHART IV

There were certain features in common in the histories of the 5 children who died. The first child "refused the breast from birth," and was artificially fed; the second child was breast-fed for five days only; the third was artificially fed; the fourth was breast-fed for three weeks; and the fifth was not breast-fed at all. The fourth child gives what might be called a "classical history of mismanagement." The child, an only and much-wanted child, was breast-fed until it was three week old. Difficulties were then encountered as the breast milk was said to disagree with it. It was then fed on cow's milk and water. This was followed by a dried milk, and this in turn by another brand of dried milk. Then a condensed milk was used, and finally a further brand of dried milk.

The child was eventually brought to the hospital when 8 weeks old, weighing 6 lb. 5 oz. It was operated on after preparation lasting three days. The infant made good progress (Chart IV) and gained weight till the sixth day following operation. It then developed gastro-enteritis and died on the eleventh day. This child should have been examined for a hypertrophic pyloric sphincter when it started to vomit while on breast milk.

A child appears to lose its immunity to gastro-enteritis if once it is taken off the breast. Never take a young infant off the breast, provided the mother is well, till the presence of pyloric stenosis has been definitely excluded. It should be regarded as axiomatic that breast milk never disagrees with an infant. This should be taught to students, nurses, midwives, and welfare and social workers of all kinds.

The advantages of a short period of treatment and early charge from a hospital ward are unquestioned. Surgery vides this.

The problem of the control of gastro-enteritis among tle-fed babies admitted to institutions is urgent for h physician and surgeon. Gastro-enteritis is the one iger to be feared in a child with pyloric stenosis ether medically or surgically treated, and its risk is portional to the duration of hospital treatment The iger is less with surgical treatment, which requires a in hospital of only eight days, than with medical tment, which takes longer.

Three typical charts, I, II, and III, are the records three infants operated on consecutively at the Infants spital on November 21 and 25, 1938. Two of the ldren were discharged on the eighth day following opera-, one having gained 12 oz. and the other 14 oz The aining child was discharged on the ninth day, having ned 14 oz. These charts are reproduced to show the idity of the improvement to be expected following cessful surgical intervention.

Technique

Prolonged pre-operative preparation is neither neces-y nor of great value. The administration of large antities of saline subcutaneously and intravenously is advised. The best way to give fluids to an infant by mouth, and the sooner the child can be placed in osition whereby it can benefit by fluid given by mouth better. Hence the sooner operation is performed the ter. The operation should be preceded by gastric age. The lavage is not given in an attempt to cure chronic gastritis, as it is difficult to believe that lavage have much effect on gastritis so long as the pylorus obstructed. Lavage is to empty the stomach of its tents and so prevent decomposing food from enter-the intestine, and to empty the stomach of gas. It uld be done a quarter of an hour before operation. a child whose stomach is full of gas is restless under al anaesthesia. Apart from this gastric lavage, no further e-operative measures are advocated or adopted. No lative or other form of premedication is necessary or sirable. The child is operated upon in a theatre the mperature of which is as near to 80° F. as possible. such a theatre is not available the child should be ced on the operating table upon two partially filled bber hot-water bottles. The temperature of the water the bottles should be tested with a thermometer, and ould be 100° F. Local anaesthesia is invariably used, d is produced by means of 1% ethocaine with or with-t adrenaline. Never more than 10 c.cm. of this solution required. These are important factors in eliminating ock. A midline incision is found to be most satisfactory. to 5 c.cm. of ethocaine should be placed sub-taneously along the line of the proposed incision. A tle less than this quantity should be divided between e rectus of each side. The remaining 3 to 4 c.cm. ould be placed deep to the linea alba—i.e., in the sub-itoneal space. The whole procedure can be carried t through two skin punctures. It is very important not eviscerate the child. Nothing should be allowed to ave the abdomen other than the hypertrophic pyloric mour. This can be delivered by the use of two pairs plain dissecting forceps. It is not necessary for the erator to put any part of the hand into the peritoneal ity. The peritoneum and muscle coat is incised down the mucosa and the abdomen is closed. The closure surprisingly easy, as the peritoneum comes together thout tension.

In a recently published textbook on surgery for udents one finds this statement: "Speed is highly important, and the mortality will depend upon the surgeon's skill." Gentleness is more important than speed. And if the child is under local anaesthesia, and the theatre is warm, speed is of little moment. The essentials of after-treatment consist of guarding the child from the "dangers of gastro-enteritis" and the slow gradual resumption of normal feeding. Appended are feeding charts which have been reproduced from the latest edition of the Infants Hospital *Pharmacopoeia*.

Congenital Pyloric Stenosis Post-operative Feeding

Artificial Feeding: Commence Three and a Half Hours after Operation

Hours after Operation		
3½	1 dr.	7.5% glucose in half-strength normal saline
4	1 dr.	do.
4½	1 dr.	do.
5	1 dr.	do.
5½	1 dr.	do.
6	1 dr.	do.
6½	1 dr	do.
7	1 dr.	do.
7½	1 dr.	Half-strength ½ Cr. C. & G. Special
8½	2 dr.	do.
9½	3 dr.	do.
12	4 dr.	Full-strength ½ Cr. C. & G. Special formula
13½	6 dr.	do.

Hours after Operation		
15½	1 oz.	Full-strength ½ C. & G. Milk Mixture
17½	1 oz.	do.
19½	1 oz.	do.
21½	1 oz.	do.
23½	1½ oz.	do.
25½	1½ oz.	do.
28	2 oz.	do.
31	2½ oz.	do.

Then 6 × 3 for 12 hours and thereafter increased according to *directions*. Water by mouth in small quantities between feeds p.r.n.

Formula (Full Strength)

½ Cr. C. & G. Special	2½ *dr.*
Dextrimaltose	1 *dr.*
Water	2½ *oz.*
Lactic Acid (*B.P.*)	10 *drops*

Breast Feeding: Commence Three and a Half Hours after Operation

Hours after Operation		
3½	1 dr.	7.5% glucose in half-strength normal saline
4	1 dr.	do.
4½	1 dr.	do.
5	1 dr.	do.
5½	1 dr.	7.5% glucose in half-strength normal saline + ½ dr. breast milk
6½	1 dr.	7.5% glucose in half-strength normal saline + 1 dr. breast milk
7½	1 dr.	do.
9	3 dr.	Breast milk
10½	4 dr.	do.

Hours after Operation		
12	6 dr.	Breast milk
13½	1 oz.	do.
15½	1 oz.	do.
17½	1 oz.	do.
19½	1 oz.	do.
21½	1 oz. 2 dr.	do.
24½	1 oz. 2 dr.	do.
27½	1½ oz.	do.
30½	1½ oz.	do.
33½	1 oz. 6 dr.	do.
36½	1 oz. 6 dr.	do.
39½	2 oz.	do.

Then six or seven feeds three-hourly. Baby put to breast if condition allows two to three days after operation.

Summary

A series of 100 consecutive operations on breast-fed infants for pyloric stenosis is reported without a death.

A similar series of 46 operations on bottle-fed infants resulted in 5 deaths, all from gastro-enteritis.

The practical implications of these results are discussed, and it is pointed out that statistics comparing medical and surgical treatment of pyloric stenosis are worthless unless accompanied by information as to the method of feeding.

I should like to thank the physicians at the Infants Hospital for allowing me to publish the records of the patients admitted under their care.

Stockholm has a scheme for collecting and distributing mother's milk for sick children. At a special centre at the principal milk distributing company nursing mothers who have more milk than their children require are examined free of charge by a physician, including x-ray examination of the lungs, blood tests, etc., and are supplied with sterilized bottles into which the milk is pressed directly from the breast. The milk is paid for at the rate of 4 kronor (4s.) a litre and as little as 1/4 litre or even less a day is accepted. The bottle is left at the nearest of the milk company's shops and taken by the company to the centre, where the contents are examined, pasteurized, and then placed in refrigerators.

OPHTHALMIC CASUALTIES RESULTING FROM AIR RAIDS

BY

DOROTHY R. CAMPBELL, M.A., M.B., B.S.

Honorary Ophthalmic Surgeon to Coventry and Warwickshire Hospital; Ophthalmic Surgeon, Warwick Hospital

We are now becoming familiar with the types of ocular injury which result from air raids. They usually occur in conjunction with other injuries and are regarded as of secondary importance, particularly during the first few days of treatment. I have had the experience of preparing an ophthalmic hospital which was closed again before any emergency arose, and of starting from " scratch " immediately after a big air raid in a hospital unequipped for ophthalmic work. It has shown me that an ophthalmic hospital as such is impracticable except for protracted cases, and that the ophthalmic surgeon must be prepared to take his instruments and equipment to any centre where his services may be required. He may be met by a total absence of ophthalmic nursing and a lack of appreciation of the importance of vision in a patient who has multiple other injuries. These difficulties can be overcome, but I mention them in the hope that those who are in charge of E.M.S. hospitals will bear them in mind. The provision of ophthalmic drugs, a skeleton set of instruments, and the inclusion on the staff of one or two nurses with ophthalmic training would greatly facilitate matters. If possible some provision should be made for the ophthalmic surgeon to operate elsewhere than in the main theatre, since the latter is likely to be occupied continuously by general surgeons for several days after a raid.

Types of Injury

There appear to be three main causes of ocular injury: (1) explosive incendiary bombs; (2) the sudden compression and expansion of the atmosphere caused by blast; (3) direct blows on the eye.

The resulting injuries present certain features and problems of treatment which are new to the ophthalmic surgeon, and an outline of my observations on approximately 100 cases may therefore provide an interesting comparison for ophthalmic surgeons in other large cities. These notes were made after the raids in October and November, 1940, and have been modified by further experience.

Effects of Incendiary Bombs

In a mild degree the effect of an incendiary bomb was that of multiple foreign bodies—particles of sand and oil were embedded in the eyelids, conjunctivae, and corneae. Whenever possible the foreign bodies were removed from the cornea immediately, flavine oil and atropine was instilled, and when only one eye was affected the patient was able to return home: the eye usually became quiet in one or two weeks.

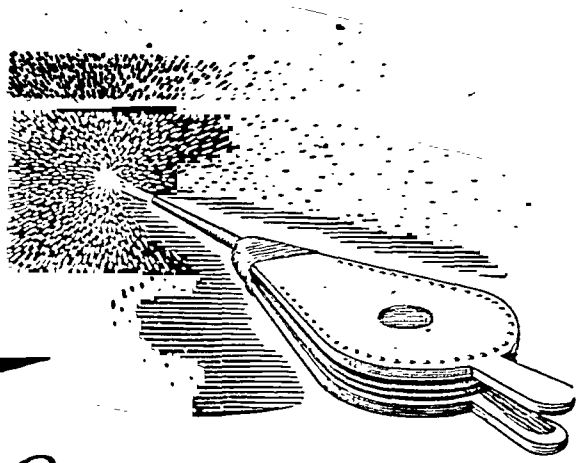
There were, however, many cases in which the eyes had been burned, and usually both eyes were affected. The lids and conjunctivae swelled, and the corneal epithelium was too oedematous to admit of removal of the foreign bodies for perhaps a week. The patients suffered severe pain and had to be removed to a base hospital, where they made a slow recovery. It was found by experience that metycain and merthiolate ointment gave great relief in the initial stages, without any ill effects on the cornea. Atropine was also adminstered, and, later, saline lotion and collosol argentum drops were employed. It was found better to remove the foreign bodies a few at a time. In one case in which a large number were removed from both corneae a week after injury an alarming infection followed within forty-eig hours; there was a general rise in temperature, and a corne abscess and hypopyon developed in both eyes. Large dos of sulphapyridine were given, followed by graduated intr venous injections of protein-shock T.A.B. Both eyes we retained; one had 6/12 vision, but in the other there was perforated cornea.

I was impressed by the softening of all the ocular tissue In addition to the softening of the cornea I noticed a pe sistent oedema of the conjunctiva; sutures put into flaps cover a perforating injury very quickly cut out, and ma cases showed lymphatic blebs in the conjunctiva which pe sisted for weeks after the injury. The sclera, too, appear to be oedematous, for two cases in which deep bu penetrated to the sclera, developed a spontaneous ruptur and prolapse of the vitreous several days after injur Secondary infection was rare, but in one case a most intrac able attack of superficial punctate keratitis occurred. T resulting vision was usually good, except in the few cas with infection of the cornea, but the eyes remained irritab and injected for many weeks, and there was permane staining of the conjunctivae.

In addition to the injuries already described, incendia bombs often caused burns of the eyelids and face whi were usually superficial and which were best treated wi sterile petroleum jelly. This facilitated the dressing of t eyes and retained the mobility of the lids.

In contrast to these, deep burns of the eyelids occurr in conjunction with extensive burns of the face in firem and A.R.P. workers directly exposed to fire. The ey themselves were usually uninjured, and this enabled t gentian violet - silver nitrate treatment to be used in t first instance, followed by petroleum jelly when the low lids became softened by lacrimation. Contraction was ve apt to occur, and necessitated stitching the eyelid margi After three months two cases were treated successfully wi Thiersch grafts.

Effects of Blast



Some peculiar effects on the eye of sudden compressi and expansion of the atmosphere were noticed: (a) Pro tosis due to a sudden retrobulbar haemorrhage causi immediate total loss of vision: the usual signs of evulsi of the nerve were absent, yet subsequent optic atrop occurred. (b) Extensive intra-ocular haemorrhage eith from an iridodialysis in which the iris vessels were to through, or from a torn retinal vessel. (c) One or more ru tures of the choroid appearing as crescentic tears near t optic disks: these were quite different from the famili contusion changes of the retina and were accompanied small haemorrhages at the macula, with loss of centr vision. (d) Acute iritis and acute secondary glauco occurred in several cases about a week after injury. The were slow to recover. Investigations were made for a constitutional factor, but they appeared to be due entire to trauma.

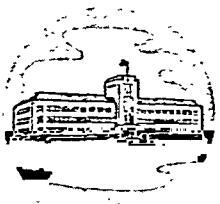
Effects of Direct Blows

Perforating injuries of the cornea and rupture of t sclera from a direct blow were common injuries, and usuall the eye had to be removed. Several cases showed a seve traumatic keratitis with multiple folds in Descemet's mem brane. Although the cornea cleared well there were alway associated contusion changes in the retina, particularly the macula, giving rise to defective vision. Several cases penetrating wounds of the orbit occurred in which lar particles of wood and glass were buried deep in the tissue but the sinuses healed up well, as did wounds of the eyelid There were no cases of intra-ocular foreign bodies requirin the use of the magnet.

Stimulant

OF THE VITAL CENTRES

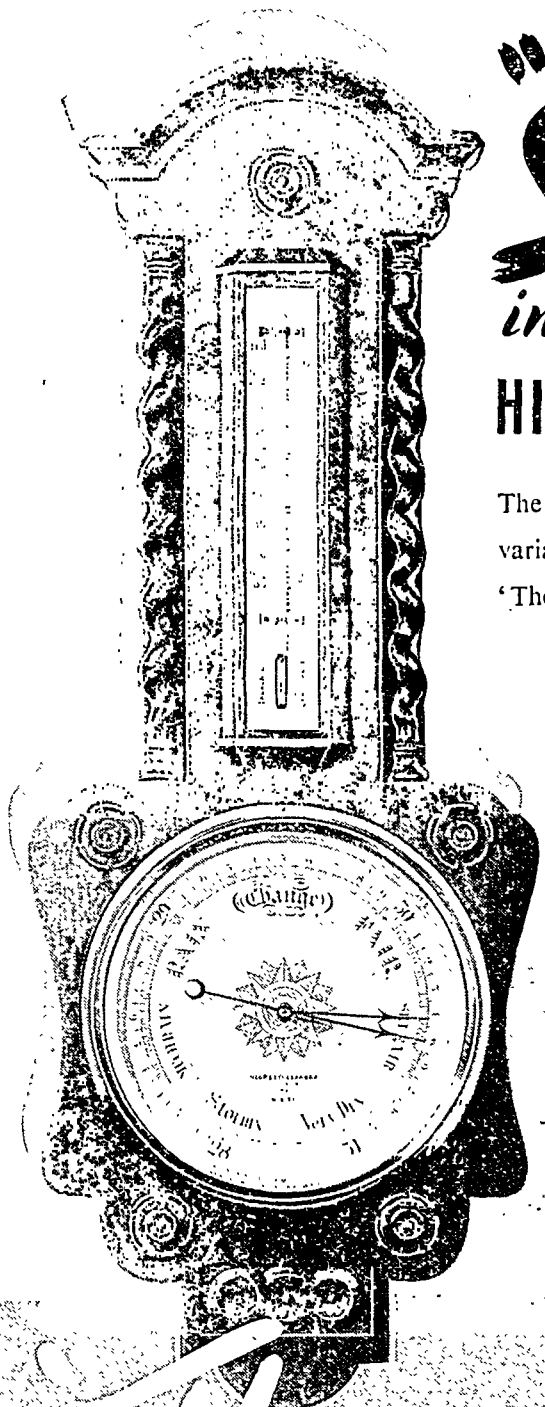
BRITISH MADE **Coramine** TRADE MARK REGISTERED



BRAND OF NIKETHAMIDE B.P.

Large doses at the critical moment
Small doses for prolonged treatment

"5 c.cm. of Coramine given intravenously is the most wonderful restorative at one's disposal . . It is so dramatically effective that it often brings the patient round to full consciousness within sixty seconds of administration."



J. R. Naval med. Service (1940), 2, 138.

A booklet, *Coramine, Stimulant of the Vital Centres*, will be sent on request to members of the Medical and Allied Professions. Samples are also available for clinical trial.

Medical Memoranda

Flat-foot in Recruits

To anyone who has been responsible for the medical supervision of recruits it becomes obvious that the condition of flat-foot in all its varying degrees is by far the commonest cause of doubtful efficiency; and it is, I think, experience alone that guides one in the most satisfactory disposal of these cases. I have therefore collected statistics as complete and accurate as possible relating to the incidence methods of treatment, and progress of all cases of flat-foot in an infantry battalion during its first six months of training.

All degrees of flat-foot have been encountered. The "severe" form, in which the head of the talus has gone right over and the flatness is "complete," causes least trouble. Some men with this condition are placed in a category barring them from an infantry regiment. Of those who are not the majority have no trouble with their feet at all, they can perform long route marches, and suffer only from blisters occurring through pressure on the boot. It is a recognized fact that the severest pain is always caused by the high arched foot beginning to give way, and I have amply proved this in my limited experience.

Treatment

I was guided by the *Army Manual of Chiropody*, Mercer's *Orthopaedic Surgery*, and that excellent monograph *Military Orthopaedics*, written by Sir Robert Jones during the last war.

Exercises.—At first I enthusiastically ordered the exercises advocated by the *Army Manual of Chiropody*. To ensure that these were correctly performed I arranged for a class to be held during the times set aside for P.T., and this was supervised by one of my medical orderlies. Sir Robert Jones stated: "If the principle of deviation of body weight on to the outer edge be loyally adhered to every ordinary case will recover, even without special tiptoe exercise." My results, however, were discouraging, and after about six weeks I discontinued this altogether. The crux lies in "loyally adhered to," and it is a crux which I considered impossible to overcome satisfactorily.

Strapping to Support the Ankle.—I did not consider this method of treatment. I had a rise of one-quarter of an inch, or one-third of an inch, according to the severity of the condition, put on the under-side of the heel and sole of both boots. At first I met with a barrier of resistance from the cobbler, who, despite most elaborate instructions and diagrams, would insist on putting a rise on the inside under the arch of the foot. This invariably aggravated the symptoms! However, I succeeded in the end in getting what I wanted.

Alteration to Boots.—This I found was the only satisfactory

Rest.—In the limited number of more acute cases which occurred a week's rest with no additional treatment was enough.

Results

Altogether 30 men reported sick with symptoms caused by fallen arches. There were 33 other men in the battalion with marked degree of flat-foot, as evidenced by footprints and arance—some with extreme splaying and eversion—who r complained. These were all of the first or second ree, in so far as the arch can be restored. Some of them exceptionally good walkers, and all have been for route rches, reminding one of the story told of the last war, en hundreds of American Indians were said to have walked thousand miles to enlist at an eastern town. On being amined they were turned down on account of "flat feet." Whereupon they proceeded to walk the thousand miles back again! It is, however, significant that of these 33 cases of "accidentally" discovered flat-foot there were just over twice as many in "HQ" company (drivers, signallers, etc., who had little marching to do) as in any one of the other companies.

Of the 30 men who complained 14 have already been before a medical board or are waiting to do so—these I class as failures; 6 are still under treatment; 4 have left the station, and so are out of touch; and 1 who only had blisters under the sole is recovering. Of the 14 who have been "boarded" 7 did not complain until the sixth month in the Army, when training became very much more severe, and all the 6 who are still being treated did not complain till the sixth month of training. The results of the 30 cases are therefore as follows: 14 failures, 6 successes, 4 lost touch, 6 doubtful. At least 3 of the last group were probable failures. Thus we have 17 probable failures out of 26 followed-up cases.

Conclusions

The conclusions which I have drawn from these figures are as follows: (1) In cases of flat-foot exercises with the limited facilities afforded by a regiment "in the field" are useless. (2) Any case which fails to respond to treatment within three weeks should be "boarded" without delay. (3) In the examination of recruits very little regard should be paid to the appearance of flat feet, and very much regard to the "foot history" of the patient. This would help to avoid the time wasted by men carrying on until training became severe at the end of six months and then "cracking up." The 14 "failures" had together already wasted six years' training.

I should like to express my thanks to Sergeant Fraser for the great care with which he kept the records of all my patients.

R. T. BURKITT,
Captain, R.A.M.C.

A Case of Prolonged Gestation

The case reported below seems to be worth recording for its medico-legal significance.

Case Record

The patient, a healthy, cheerful, and intelligent woman of about 9 stone, aged nearly 35, did not begin to menstruate until the age of 18. The menstrual cycle has always been a consistent 56 days, regular and painless. By her first husband she had two healthy children—a girl aged 12½ who weighed 9 lb. and had one tooth at birth, and a boy aged 10 who weighed 7½ lb. Both pregnancies were abnormally long—"about an extra month." The first labour was prolonged (four days), and was ended by forceps; the second labour lasted two and a half days, but was otherwise normal.

As the result of a motor crash she was told that it was unlikely she would have more children, and when she married for the second time she took no precautions against becoming pregnant. Her second husband went on war service on March 15, 1940, leaving her with her father and mother, both over 80, on a small-holding on Dartmoor. Her period had ended on March 8. Before the end of March she had symptoms which from her previous experience convinced her she had become pregnant.

By December an active child in normal vertex position occupied an apparently full-time uterus. At nine and a half, and again at ten, months quinine was tried to induce labour, with no other result than "an extra good night's sleep." On February 7 she delivered herself in eight and a half hours of a healthy male child weighing 8½ lb., fully mature and with the fontanelle more closed than usual.

The grandmother was nearly 48 when the patient was born, and all five of her children were carried "over-long." but no exact data can be obtained. March 14 to February 7 is 330 days.

Newton Ferrers. W. F. BENSTED-SMITH, M.B., B.Ch.

The existing arrangements whereby local authorities were authorized at the expense of the Exchequer to provide nursery schools for children under 5 who had been evacuated are to be extended, and Wartime Nurseries for all children under this age, including those of women in employment (whether the latter have been evacuated or are local residents) are to be established in all areas according to local needs. They may be part-time nurseries open approximately during school hours or whole-time nurseries open for periods up to 12 to 15 hours, and medical officers of health are to make arrangements for the regular medical inspection and supervision of the children.

Reviews

PERVADING INTELLIGENCE

Life Magnificent. By Henry Atkinson. (Pp. 316. 7s. 6d. net.) London: Watts and Co. 1941.

The human brain was not developed for the purpose of thinking about the illimitable but to enable man to contend with his immediate environment; therefore reason, being dependent on the brain, cannot really grasp abstractions. Nevertheless, his boundless curiosity will always urge man on to a pursuit doomed to inevitable failure, but yielding many rewards by the wayside. This we take it is the purpose of Mr. Henry Atkinson's *Life Magnificent*, in which he emphasizes two principles—an all-pervading intelligence in the universe, and the non-intervention of any power external to that intelligence. This is not quite so remote from Bishop Berkeley as the author seems to think. It is too often forgotten that the bishop did not claim that material things only existed in our thought, but, with Plato, that they also existed in the mind of deity. True he differs from them when he says that "intelligence is within the universe, within existing things, within all development, not outside it, and that in consequence everything consists of Intelligence itself." But when he goes on to say, "Intelligence has developed in the same manner as that of man and all organic forms; it is not an autocratic dictator . . . it knows no more of what man may become than man himself does; it endeavours to tune existence to finer harmonies," he is really in agreement with the philosophy of Prof. S. A. Alexander, though starting from different premises. The author was led to his conclusions from watching the healing of a simple wound, a profoundly impressive spectacle to any thinking mind, which convinced him that here was an obviously intelligent sequence. He argues back to the postulate of a primitive unit which he labels the mitron and maintains that, if we reject the development of the universe from the movements of such a primitive particle by means of its own intelligence, we must accept the separate creation of all sorts of energy and matter which have adjusted themselves to one another by a truly marvellous series of miracles. The physicist suggests that his waves which result in definite impressions on our senses have no material existence; Mr. Atkinson suggests that "if one can swallow that camel, there need be no straining at the gnat of Intelligence."

This thesis is skilfully maintained by abundance of scientific illustrations ranging from spiral nebulae to sociology. It is a pity therefore that the index should be wholly inadequate to a book of this importance. For the author is anxious to turn his theories to practical use in the conduct of life by showing how the evils of the artificial conditions of man's present physical and mental life lead frequently to disaster, and how his future welfare depends on the perfect association between his individual intelligence and that of his environment. By way of illustration he asserts that perhaps the greatest tragedy of mankind was the disappearance of Cro-Magnon man some 20,000 years ago, for he regards this as a higher type than the one from which the existing races developed. It is indeed a recurrent tragedy that the more civilized races tend to be destroyed by the more brutal when they have acquired an ease of living which gives them a higher sense of values. It is a tragedy which impends like a sword of Damocles over civilization to-day.

Space forbids more extensive quotations, but we cannot omit the author's criticism on the laboratory attempts to interpret the nature of matter from the results of violent ...tting of the atom: "Are we to discover the intelligence involved in the erection of a noble cathedral from th manner in which it is blown to pieces?" We must l content simply to refer the reader to his views on th origin of life (p. 207).

The book "is addressed to Youth, because only you will dare to tread a path so startlingly new." Yet its new ness is not so subversive of older philosophies as to rend its pages unpalatable to those of riper years, who are alive to our present dangers as are the most callow. W have read it with great interest, though we might sugge as a more descriptive if less sensational title, "Th Immanence of Intelligence."

THE BIOGENIC AMINES

Die biogenen Amine. By M. Guggenheim. (Pp. 564. No price given.) Basel and New York: S. Karger. 1940.

Dr. Guggenheim has long been recognized as the outstan ing authority on the amines present in organisms, and a biochemists will therefore welcome the appearance of th third edition of his monograph on the biogenic amin and their importance for the physiology and pathology vegetable and animal metabolism. The last editio appeared in 1924, and knowledge in this field has advanc greatly since that date; hence the present volume is pra tically a new work. The author remarks that the increa in knowledge has been so great that it is no longer possib to make a complete presentation of the subject in a sing volume.

The monograph gives a full account of modern kno ledge of well-known and important amines such as acety choline, histamine, and adrenaline, and also provides systematic survey of their less famous relatives. Th latter feature is of special importance because is so much easier to obtain information about wel known substances than about substances which ha not attracted general attention. Besides describing th amines that occur in nature the author also mentio the additional forms produced by the organic chemist. Th number of these precludes more than a bare descriptio For example, a simple list of the known phenyl alk amines occupies ten pages, while a similar list of th homologues of choline occupies eight pages.

Dr. Guggenheim has managed to compress an enormo amount of information into a single volume, and bi chemists and physiologists in general will be very gratef to him for the labour he has expended in providing a authoritative account of an important and difficult subjec

APPLICATIONS OF X RAYS

Applied X-Rays. By George L. Clark, Ph.D., D.Sc., Professor of Chemistry, University of Illinois. Third edition. International Series in Physics. (Pp. 674; illustrated. 42s.) London: McGraw-Hill Publishing Company, Ltd. 1940.

The third edition of this book contains an up-to-dat account of the applications of x rays in science an industry. The direct medical interest in the work is ver limited. A paragraph or two are spared to the subje of medical radiography. There is a fairly comprehensiv chapter on the biological effects of x-radiation, whic includes a brief outline of work on radiogenetics. Th effects of radiation on normal and pathological tissue a summarized. This part is of restricted value from i very brevity. For example, on page 213 the statemen "28 and 34 per cent. respectively of an erythema dos (600 r), effective in the ovaries, will produce temporar and permanent sterilization" has little value without refe ence to the patient's age; and the "statistics of the cance problem" can hardly be summarized adequately in a sho paragraph of a dozen lines, as on page 219.

The technique of radiotherapy does not come into the scope of the work. The physics of x-radiation are dealt with concisely and clearly, though the chapter on "Scattering and Absorption" is too sketchy to be very informative. There is a condensed account of the modern method of describing the vector model of the atom. A superficial knowledge of the rules of quantization is assumed.

The main interest of the work lies in the last two-thirds, which is devoted to an excellent account of x ray analysis of the ultimate structure of materials, both organic and inorganic. Of particular merit is the chapter on the fundamentals of crystallography and x-ray methods of crystal analysis, which will prove helpful to research workers taking up this study. The later chapter on the interpretation of diffraction patterns presupposes familiarity with the complex mathematics of the atomic and crystal "structure factors." Finally there is a discussion of some practical applications in the metallurgical industry and in the study of synthetic materials.

Notes on Books

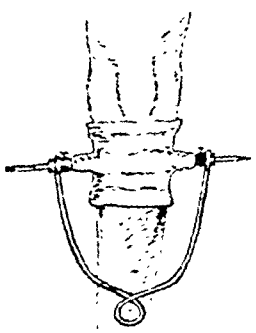
Dr. HUGH MORRIS's *Medical Electricity for Massage Students* was commended in these columns as a clear and practical textbook when the first edition appeared six years ago. A second edition is now published by J. and A. Churchill at 8s., and the author in his preface says that it differs so much from the first that it is really a new book. He has revised and compressed the material, and added new chapters on diathermy and ultra-violet rays. It is essentially for the groundwork it provides that Dr. Morris's book is valuable, and mastery of its contents will give a sound basis for all the more advanced electrical work.

A second edition has been published by Dale, Reynolds and Co., Ltd., at 1s. 6d., of Major NORMAN HAMMER's pamphlet *First Aid for War Casualties*. This handy practical guide first appeared in September, 1940, and went rapidly through four reprintings. The material has now been brought up to date and enlarged. In its revised form the pamphlet will no doubt have a ready sale among those engaged in civil defence first aid work. The author has had large experience in ambulance work, and was for some time medical adviser to the Home Office A.R.P. Department.

A review of Dr. ALBERT C. SNELL's *Treatise on Medicolegal Ophthalmology* appeared in the *Journal* of May 17 (p. 753). The publisher of the book in this country is Henry Kimpton.

Preparations and Appliances

FIXATION OF SKELETAL TRACTION PINS



Mr. D. V. MARSHALL, M.B., F.R.C.S.Ed., F.R.F.P.S.G., writes:

At the Beverley Road Hospital, Hull, some five years ago skeletal traction for the treatment of fractures of the lower extremity requiring prolonged extension was adopted almost as a routine. It was found that, apart from the accepted general efficacy of the method, the nursing of the cases was made much easier and pressure sores of all kinds were avoided.

Many of the patients who had to be treated were elderly, in poor condition, restless, non-cooperative, and occasionally demented. It was noticed that when through these causes the transfixion pin slipped transversely or by rotation, or because it had not been driven at right angles to the traction axis, infection developed at an early date. In other cases, where there was no slipping or working on the pin, infection did not occur. These results were noted constantly, irrespective of whether the skin wounds around the pin exits were dressed by various methods or left exposed. Having regard to these observations, attempts were made to devise some mechanical means to prevent the pin moving either transversely or by rotation in the tissues. Experiments were tried with various distance pieces screwed on the ends of the pin impinging on the bone through the soft tissue, and with fins on the pin (Smith Petersen style), but the results were not encouraging, and the apparatus was costly to make up. Accidentally, it was discovered that an arrangement with plaster-of-Paris described later solved the problem.

The results have been so consistently good, whether used in the elderly, the demented, children, adults, or air-raid casualties, that it is felt the method is worth recording.

The average case under my care has the pin left in until the need for extension ceases, usually eight weeks, with gradual reduction of the weight from six weeks onwards. On many occasions the pins have been left in for ten to twelve weeks.

In no case has there been any sepsis or trouble of any kind, and all the pin tracks have healed at once when the pins were removed. I have not noticed the method in use in any other hospital, or heard of it from other surgeons, though it is more than likely that others have devised similar measures with similar results.

The method is shortly as follows: A Böhler's or Steinmann's pin is introduced through the tubercle of the tibia, condyles of femur, or os calcis, or other site, as may be suited to the particular case. The skin around the pin is painted with picric or a similar antiseptic, and a paster-of-Paris bandage is applied immediately around the leg and pin in the form of a collar three or four inches wide. The distal and proximal margins of the plaster collar are prevented from pressing injuriously upon the skin by pieces of white felt. The extension stirrup having been applied, distance pieces integral with the collar are formed by winding the bandage round the pin outward to the stirrup bushes. The plaster is moulded carefully with the hands to fit leg and pin as it sets, and no dressing is used between the skin puncture and the plaster.

The method has been found satisfactory even when the pin is not driven square and it can be used to give oblique traction in fracture-dislocations of the ankle or knee. The accompanying sketch illustrates the arrangement.

The annual general meeting of the London and Counties Medical Protection Society was held on June 18 under the chairmanship of Sir Cuthbert Wallace. The annual report stated that during the past year 1,192 practitioners had been elected to membership, 917 of them within twelve months of their registration. The losses by death, resignation, or default numbered 699. Over 1,000 applications for advice and assistance from members were received during 1940—a decrease as compared with the previous year, but including a larger number than usual of serious cases. It is pointed out that no practitioner, however competent or discreet he may be, and to whatever branch of the profession he belongs, is immune from litigation on account of his professional work, and that practitioners holding Government or municipal service posts have just as much need of protection as those in general or private practice. Service with H.M. Forces does not relieve an individual of his civil obligations, and the experience of the past year has demonstrated the soundness of the advice given to Service members that they should continue their membership. A few of them have resigned in spite of this advice, and some have realized later that such discontinuance was unwise. During the year over 600 matters were referred to the solicitors, many of them concerning altered circumstances arising out of the war. An unusually large number of cases have been defended in the courts, mostly with satisfactory results. The accumulated funds of the Society amount to just upon £80,000. At the meeting Sir Cuthbert Wallace was re-elected president, Dr. G. F. Stebbing chairman of council, Mr. W. M. Mollison treasurer, and Dr. R. W. Durand secretary.

THE DANGERS OF DUST

One of the major lines of medical progress during the present war has been the study of air-borne infection. The effect of this intensified study has been profoundly to alter our conception of how infection is spread through the air, and in fact largely to restore beliefs which were chiefly current half a century ago. Dust has always been recognized as a vehicle of infection, but it was relegated to a secondary status by Flügge's work on the aerial dispersion of fluid particles from the upper air passages, and "droplet" infection has been regarded almost throughout this century as the principal mechanism by which pathogenic bacteria of many kinds are able to travel from person to person. This belief had to be qualified more recently in view of Wells's work on the behaviour of fluid particles in air: he showed that in an ordinary atmosphere a drop of fluid either falls to the ground or, if smaller, evaporates before it reaches the ground, leaving a "droplet nucleus" which remains suspended in the air. These particles if derived from natural secretion would consist of dried mucus containing bacteria which are known to be capable of survival in them for hours, or even days. Droplet infection of the more distant kind was thus merely translated into terms of droplet nucleus infection: the material concerned is certainly dust, if you will, but the supposition remains that suspension in the air continues until the micro-organism reaches a new host.

It is chiefly in connexion with streptococcal infections that even this qualified belief in Flügge's original doctrine has now apparently to be abandoned. To apply conclusions recently reached about the behaviour of pyogenic streptococci outside the body to infectious disease generally is unjustified; it remains possible, and indeed likely, that purely aerial spread is the important mode of transmission of some of the specific fevers and of many infections involving the air passages and lungs. We have little new knowledge on these subjects: on the epidemiology of streptococcal infections we have much. There have been strong motives for acquiring it, of which the foremost was the deplorable mortality from puerperal fever. There is a peculiarly exact method of acquiring it, thanks to the immense achievement of the late Frederick Griffith in establishing the thirty serological types of *Streptococcus pyogenes* by which his name will always be remembered. Aided by this delicate means of tracing the migration of a streptococcus from patient to patient, ward epidemics have been increasingly studied, and it is now widely known that under the average hospital conditions one patient may infect many others, the manifestations often varying from case to case, taking the form of a wound infection in one and a throat infection or otitis media in another. These epidemics have always existed, particularly among children, and (as was first clearly pointed out by the late C. C. Okell) in ear, nose, and throat wards; they become a major and constant problem where large numbers of war wounds have to be treated. Exactly how infection spreads in these circumstances is therefore a question of the first importance.

There are certainly two main avenues to be considered, one of which is contact infection. That imperfect technique does lead to the direct transference of streptococci, particularly from wound to wound, has been well brought out by the recent observation of A. A. Miles and his collaborators.[1] The alternative route is aerial, and here the patient suffering from a throat infection or the "throat carrier" has been looked upon as the usual source, and the vehicle of infection as the infected particle suspended in the air. There are two reasons for altering this view. One is the recent work of R. Hare,[2] who studied the expulsion of infected droplets by streptococcus carriers by an ingenious method involving the exposure of blood-agar plates disposed round an arc of a circle whose centre was the carrier's mouth. He found that haemolytic streptococci are ejected only in comparatively small numbers, and that they are contained chiefly in large droplets which fall rapidly, forming colonies only on those plates in his experiments which were below the mouth rather than on those level with it. There is much conflicting evidence about the extent to which bacteria are ejected from the mouth in talking, and a factor often overlooked is that pathogens may be localized in a particular area in the throat, whereas indicator bacteria such as *Chr. prodigiosum*, used in experiments on this point, are universally distributed throughout the mouth. Earlier observers have also failed to detect the expulsion of haemolytic streptococci by carriers in a manner and on a scale which would explain their supposed aerial infectivity. On the other hand, while the suspended droplet has been slowly falling into discredit, dust as a vehicle of infection has been receiving more and more attention and the support of many practical observations. We referred recently[3] to the studies of H. D. Wright and his colleagues on cross-infection in diphtheria wards: they found large numbers of virulent diphtheria bacilli in ward dust and established that these were capable of survival for at least a month. That haemolytic streptococci can exist in the same medium has been proved repeatedly, and ward dust, particularly that shaken up during the process of bed-making, must now be regarded as a major source of danger.

There are two ways of combating this, directed respectively to the floor and to bedclothes. The treatment of floors with spindle oil, as recommended by M. van den Ende, D. Lush, and D. G. ff. Edward,[4] is simple as well as effective. The "oiling" of blankets, which are readily contaminated by patients and at the same time a prolific source of ward dust, is not so easily carried out. When the necessary apparatus is available the result is not disagreeable to the patient, and the effect is striking. With the collaboration of van den Ende the process has been given a practical trial in two hospitals, experience in one of which he describes with E. T. C. Spooner,[5] while in another the results are

[5] Ibid., 1941, 1, 715.

scribed on page 983 of our present issue by Wing-Cdr
Squadron-Leader Major J. C. Thomas. Here elaborate obser-
vations were made which reveal the very large numbers
of streptococci that may be contained in blankets and
in wool dust generally, and confirm the increase in
aerosphere contamination that results from bed making
and other disturbances. The old treatment of blankets
is certainly effective in reducing this, and its general
adoption will have to be considered seriously. No one
reading these papers can deny that our whole outlook
in the epidemiology of streptococcal infection has been
changed, and that preventive efforts must take a new
direction. To correlate Hare's findings with recent
statistics in detail, it must be concluded that large droplets
and infection drying on bedclothes and floors are the
principal agency in spreading infection from the air
passages: exudates drying on dressings and persons
probably behave in the same way when the surface
exhibits a wound. Other ways of dealing with the
problem will no doubt be devised, but to us it
seems that the terrible evil in both its forms deserves every effort
to be done.

A sharp outbreak of yellow fever in the Sudan led to the Foundation's supplying a quarter of a million doses of vaccine, and preparations for the supply of at least a million in all. Their researches show that yellow fever is primarily a disease of jungle animals; the virus circulates in the blood of susceptible ones for only three to four days and does not subsequently appear to reinfect. Mosquitoes, however, once infected tend to carry the virus for the remainder of their lives.

After detailing several other activities of the Foundation Dr. Fosdick goes on to an interesting discussion of the sharp attack on science resulting from the growing public realization that its powerful tools can be used for man's enslavement and destruction. Power can be used by evil men to do evil even more than it can be used by men of good will to do good; but, as he says, "Power is one of many things in life, and he quotes Plato: "Power to the effect that the spread of the truth is the only guarantee against whole-sale mendacity by propaganda." The question for the future is how can the social adjustment of human affairs be arranged with less frustration and more justice. The hard fact is that scientific work may not do

There is much food for thought in this report of disappointments of expectations and of fears. One striking fact emerges—the total expenditure for the year on all the beneficent work of the Rockefeller Foundation was roughly 24 million sterling, a trivial sum compared with the cost of the destructive forces at work today.

A WARTIME SURVEY

The wealth of the Rockefeller Foundation flowed from
endowed by the irony of fate its beneficent work is now
seriously curtailed by the struggle for the power that
could can give. This makes Dr. Fosdick's review of the
year's work of the Foundation grim reading. All over
Europe its activities have been brought to a stand-still.
"Even in the shadows that are deepening over that conti-
nent the lights of learning are fading one by one. The
conception of knowledge as an international respon-
sibility has vanished. . . . As German forces have moved
into one country after another a definite pattern has
been followed." Where this was resisted, faculties were
sent to concentration camps and student demonstrations
were broken up with machine guns and tanks." The
tradition of university life and standards on the Conti-
nent is now little short of appalling. Due to flight,
imprisonment, or disappearance the number of professors
has been reduced by at least 50%." The same applies
to the Baltic States absorbed by Russia. Even in neutral
countries scholars are under pressure to follow a
totalitarian interpretation. The German Minister of
Justice gave as his opinion that the old ideal of
objectivity is nonsense: the one question must be, Does
any scientific work serve the welfare of National
Socialism? But, "In all the history of the race know-
ledge has never flowered in a subject people . . . it is
only through free thought that the soul of a people can
be kept alive."

Turning to brighter topics, Dr. Fosdick reports the
success of the campaign against the *Anopheles gambiae*,
the dreaded malaria-carrying insect which was imported
from Africa to Brazil by an airplane or fast French
destroyer plying from Dakar. The virulent outbreak of
malaria which followed is an interesting example of the
fact that epidemics travel at precisely the rate of human
intercourse; formerly at the speed of a horse or sailing
vessel, now at that of a plane. Thanks to the efforts
of Dr. Soper and his staff no evidence of *gambiae* in
Brazil was found in the last forty-seven days of 1940,
though probably certain mopping-up operations remain

THE LESION OF PNEUMOCOCCAL LOBAR PNEUMONIA

The criteria for the experimental production of pneumococcal lobar pneumonia were laid down by Blake and Cecil in 1920.[1] The cocci must be deliberately placed in the lumen of the trachea or of a bronchus in a susceptible animal. Subcutaneous or intravenous injection gives rise to septicaemia with very occasional secondary lung lesions or is without effect; inoculation into the nasal or upper respiratory passages is usually negative. Blake and Cecil suggested that the infection traversed the lung from its hilum as a wave of acute spreading lymphangitis of the interstitial tissue, the cocci travelling in the peribronchial and perivascular lymphatics, the alveoli being invaded from without. On this view the peripheral parts of the lung should always show oedema or early consolidation when the lesion at the hilum shows well-developed lobar consolidation. The conditions laid down by Blake and Cecil have become part and parcel of the experimental study of lobar pneumonia, but their conclusions regarding the evolution of the lesion have been strongly attacked. Loeschcke,[2] in 1931, examined the lungs of forty-seven fatal human cases of lobar pneumonia and claimed to have discovered the primary focus of infection in them all. According to Blake and Cecil this should have been found near the hilum. Loeschcke always found it to be at the periphery, usually in a dorsilateral position. He satisfied himself that the spread of infection was from alveolus to alveolus through the pores of Kohn, that the infective agent was freely flowing oedema fluid in which very large numbers of pneumococci were growing but in which cells were scanty, and that as this fluid increased in volume it was spread by coughing and movement, travelling in the

1 *J. exper. Med.*, 1920, 31, 403, 445; 32, 401, 691, 719.
2 *Beit. z. path. Anat.*, 1931, 86, 201.

small air tubes. Terrell, Robertson, and Coggleshall[3] produced lobar consolidation of the lungs in dogs by introducing pneumococci suspended in a viscous starch emulsion into a terminal bronchus by means of a fine catheter. They found spread to take place radially from the primary focus and the pneumococci to be carried in large numbers in oedema fluid which travelled along the small air tubes. Suspension of the inoculum in a viscid medium protects the pneumococci from phagocytosis, allows them to proliferate locally, and prevents their wide dispersion.

Hamburger and Robertson[4] have recently published an account of experiments which give strong support to the contention that lobar pneumonia spreads from a primary focus in the lung by aspiration into the fine air tubes of pneumococcus-laden oedema fluid. They have taken the matter further, and offer a reasoned explanation, founded on accurate experiments in dogs, of the mechanism of spread of the disease from lobe to lobe and lung to lung. The first problem was to determine the exact anatomical disposition of the main bronchi and their main lobar branches. This was done by making metal casts of the bronchial tree. Primary foci of lobar consolidation were then established at different sites in the lung in a series of animals by injecting pneumococci in 6% starch broth into a terminal bronchus. For each primary site the location and order of appearance of secondary lesions arising from it were determined. For instance, with a primary focus in the right lower lobe the secondary foci appeared in the right middle, right upper, and post-cardiac lobes in this order. Having regard to the fact that the habitual posture of the animals was prone with the head and upper thorax slightly lower than the rest of the body, and by reference to the metal cast, it was demonstrated that the factor deciding where secondary lesions shall appear and in what order is the flow, purely under the influence of gravity, of oedema fluid from the primary focus. It was repeatedly observed in those animals with secondary foci that the primary lesion was much more oedematous than when secondary lesions did not arise. In a word, the spread from lobe to lobe depended in the first place on the degree of acute inflammatory oedema in the primary lesion, and the situation of the secondary lesions in the lung on gravity. This is borne out by further experiments. Cultures from different parts of the lungs were taken from animals with a single lesion and from others with a primary and several secondary lesions. In the first group pneumococci were strictly limited to the primary lesion. In the second, the primary lesion being "wet" and oedematous, there was spread of oedema fluid, and pneumococci were found throughout both lungs. An attempt was then made to induce a secondary focus of pneumonic consolidation in a part of the lung remote from the primary focus by plugging with viscid fluid the fine air tubes to a lobe. This was done by injecting mucoid by a fine catheter introduced through a bronchoscope into the bronchus to a lobe. In a series of nineteen animals no secondary lesion developed in the "plugged" lobe in sixteen. It is therefore reasonable to conclude that the site of a secondary focus is not determined by absence of the normal mechanism for expulsion of fluid from the airways. A series of animals was then infected by injection of the freely flowing watery exudate taken from the air passages of dogs with severe lobar consolidation. Secondary lesions were readily produced by maintaining the animals in positions favouring the flow of fluid to the depths of the lungs, and lesions in various lobes could be obtained at will by varying the position of the animals. When viscid slowly flowing exudate from lesions showing less acute inflammatory oedema was used consolidation did not appear.

"THE BIRTH OF A BABY"

About eighteen months ago a film entitled "The Birth of a Baby," which had been produced by the American Committee on Maternal Welfare, was sponsored in this country by the National Baby Welfare Council. In some comment in these columns at the time it was remarked that the educative value of the film was undoubtedly high, though it had an opulent American setting which might make it seem rather unreal to the British mother, but that there was nothing in it to shock "even a congregation of churchwardens." Since then it has had to run the gauntlet of the licensing authorities, numbering in some counties twenty or thirty or more, and in others, like London and Middlesex, only one—namely, the county council. A striking difference in the attitude of the authorities to such a film is shown as between the north and the south and west of England. In Lancashire, out of 65 licences required, passes have been given in 58 cases, and refusals in 4, including Warrington and Blackburn. In Yorkshire, out of 55 licences required, passes have been given in 36, and refusals in 6, including Sheffield. In Northumberland and Durham, out of 57 licences required, passes have been given in 41, and refusals in 5 (the refusals include Durham city, where the authorities have declined three times even to see the film). On the other hand, in London, after a preliminary showing at Hammersmith, further licences for cinemas have been refused, and, as showing in town halls and similar buildings is impracticable, a further request is now before the Entertainments Committee. In Middlesex the county council will not permit it anywhere. In Cornwall, where, incidentally, the infant death rate is more than 2% above the average, the county council has refused to see it or pass it. Nevertheless, with many decisions still outstanding, the film has been approved by 77% of the authorities approached and has been seen by about two million people. In Lancashire helpful co-operation is reported from all the 26 boroughs that have passed it, and an excellent response from the public. In spite of anything that Shakespeare may have said, there remains a great amount of importance in a name, and although the film itself contains nothing to offend the susceptibilities of the public, a different title, such as "Safe Motherhood," might not have aroused the squeamishness which has operated against the film in certain quarters.

MILK SUPPLY IN TIME OF WAR

Before the war the total milk production of this country was about 1,500 million gallons per annum. Of this an almost constant amount throughout the year was sold in the liquid milk and cream market. During the summer months a considerable surplus was available for manufacture, and a much smaller surplus during the winter. Roughly equal quantities of milk were used for the production of cheese and of condensed and dried milk, and a quantity equal to these two together for the manufacture of butter. According to Dr. Norman Wright,[1] the Director of the Hannah Dairy Research Institute, who gives these figures, a fall in the total milk production of the country equivalent to 25% of the pre-war figure is to be expected in the near future if the present policy of the Ministry of Agriculture is continued. This will result in a serious shortage of liquid milk during the six winter months, amounting to about 73 million gallons. No surplus for manufacture will be available during the winter, and to make good the winter deficit in liquid milk practically the whole of the summer surplus will have to be used for the manufacture of condensed and dried milk. Only 7%, in fact, will remain for conversion into cheese and butter. It is doubtful whether the existing

[1] "The Milk Supply in Time of War," *J. roy. agric. Soc. England*, 1941, **101**, Pt. ii

lants could deal with the surplus available, and unless, herefore, dried and condensed milks were imported the ountry would have to reduce its milk consumption during ie winter months to an undesirably low level.

Dr. Norman Wright analyses the position and is of the inion that this fall of 25% could and should be avoided xperience during 1914-18, when there was a similar fall, howed that it was due not to the increase of arable at the xpense of grass land, but to the scarcity and high price f feeding stuffs and to a deterioration in the quality of ats and cereals for cattle. Under the present rationing cheme preference is given to dairy cattle in the allocation f feeding stuffs, but though this will ensure an equitable istribution within each priority class, it will not increase he total amount of feeding stuffs available. In the last ear the import of feeding stuffs for animals fell to 40% of he pre-war level, and there is reason to believe that in he present war an even greater fall may occur. The only emedy, therefore, lies in an increased home production of eeding stuffs for cattle. This might be done in two ways. irst, more grass should be grown, particularly for use in pril and August, in order to reduce the consumption of urchased feeding stuffs. Secondly, farmers should be ncouraged to produce silage, using for this purpose herbage n the young leafy stage, when its nutritive value and rotein content are at their highest. It is calculated that f every moderate-sized farm in the country were to produce nly one 35-ton silo of high-quality material, which could e obtained from a single cutting of seven acres of good rassland, the result would be the conservation of three illion tons of silage—an amount sufficient to produce over 0 million gallons of milk, or nearly the whole of the 25% nticipated deficiency. The production of milk constitutes he most economical method of converting feeding stuffs nto animal products, and the maintenance of the milk upply should be the most important objective of wartime usbandry. It is to be hoped, therefore, that the suggesions put forward by Dr. Norman Wright will not only eceive the careful consideration of the Ministry of Agricul-ure, but will, if sound, be translated into practice before t is too late.

CHEMOPROPHYLAXIS OF RHEUMATIC FEVER

We have referred before to the efforts made at two centres n the United States to prevent recurrences of rheumatic ever by prolonged administration of sulphanilamide. As uch as 3 grammes daily has been given even to children or as long as eight months with no apparent ill effects, and heumatic activity seems to have been suppressed while he drug was being taken. A further and more detailed ccount of this study at Baltimore, where it has now been n progress for four years, is given by Caroline B. Thomas, . France, and F. Reichsman.[1] The subjects were out-atients leading ordinary lives, and were allocated to reated and control groups in such a way as to make the wo groups as similar as possible. Two doses each of 1.6 gramme of sulphanilamide were given daily, the first on ising and the second twelve hours later, the resulting oncentration in the blood varying between 1 and 3 mg. er 100 c.cm.; this treatment was begun each year in October and continued until the following June. Very few atients experienced any ill effects; only two patients uring the past two seasons were transferred to the control roup on account of intolerance, although others were also ransferred who failed to take the drug regularly through orgetfulness rather than any objection to its effects. The esults may be stated shortly by saying that during seventy-ine "person-seasons"—a season being the annual period of medication—involving fifty-five patients, there were no major rheumatic attacks, whereas fifteen such attacks occurred during 150 person-seasons in the control group of sixty-seven patients. It was also found by repeated pharyngeal swabbing that haemolytic streptococci were less often to be found in the throats of the treated group or were present in smaller numbers. None of the treated patients died; one control patient died from acute rheumatic fever and two of subacute bacterial endocarditis. Minor rheumatic manifestations were seen in two cases during treatment, and one treated case had a major rheumatic attack in August when medication had been suspended for the summer months. These findings seem to show clearly that rheumatic activity can be suppressed by sulphanilamide treatment and that the small dose which suffices can be taken without discomfort or interference with an ordinary life. It is interesting to speculate on the meaning of this effect with reference to the aetiology of rheumatic fever. It is, of course, possible that some agent other than the haemolytic streptococcus is concerned in producing the disease, and that this second hypothetical micro-organism is also susceptible to sulphanilamide. On the other hand, it is just as reasonable, if not more so, to regard the therapeutic argument as further evidence of the essential part played by haemolytic streptococci themselves. This evidence is only additional to an imposing mass of data accumulating from other directions. The serological studies of Coburn and others have recently[2] been extended with such results as to suggest strongly that streptococcal infection remains active throughout a rheumatic attack, while C. A. Green[3] and others have actually cultivated the organism from affected tissues, notably heart valves. It may well be asked why, if rheumatic fever is an infection by the *Streptococcus pyogenes*, the acute stage should not be amenable to sulphanilamide treatment; it seems to be generally agreed that it is not. This question may perhaps be countered by another: Why is sulphanilamide of so little benefit in scarlet fever? The haemolytic streptococcus is the most versatile organism we know; it has several weapons of attack, and the capacity to produce an astonishing variety of effects, not all dependent on the nature of the tissue affected. It may well be that certain forms of streptococcal activity are less amenable to chemotherapeutic control than others, and if we conclude that rheumatic fever is one of these, the fact of its resistance to chemotherapy may even afford a clue to its more intimate mechanism.

Sir Charles Wilson, P.R.C.P., has been appointed Consultant Adviser in Medicine to the Minister of Health for the Emergency Hospital and Medical Services.

We regret to announce the death at the age of 57 of Robert Robison, D.Sc., F.R.S., head of the department of biochemistry at the Lister Institute of Preventive Medicine since 1931, and professor of biochemistry in the University of London. Prof. Robison joined the Lister Institute in 1913, and served with a commission in the R.A.M.C. during the last war. He received the Baly Medal of the Royal College of Physicians of London in 1933 for his distinguished work in physiology.

At the course arranged by the Ling Physical Education Association to take place at Leeds University on Saturday, July 5, Dr. M. Burbury, medical director, Manchester Child Guidance Clinic, will lecture on "Interactions of Mind and Body," and Dr. G. Prince, assistant school medical officer, Leeds, will open a group-discussion on "Co-operation between the School Medical Officer and the Gymnastic Teacher."

CHEST SURGERY IN WAR

This is one of a short series of articles based on lectures given at the British Postgraduate Medical School, Hammersmith

CLOSED WOUNDS OF THE CHEST, AND THE PHYSICIAN'S PLACE IN A CHEST TEAM

BY

J. A. NIXON, C.M.G., M.D., F.R.C.P.

Changes in climate, the nature of the soil, the character of weapons and missiles, render the aspect of gunshot wounds of the chest exceedingly variable. In the South African War it was decided that chest wounds were best left to the natural processes of cure. In the war of 1914-18 sepsis was so frequent in all varieties of chest wound that by 1916 Duval of the French Army and Gask of the British Army first began to apply the general rules of surgery to lung wounds. In July, 1917, a meeting of consulting surgeons and physicians drew up a memorandum which was communicated as a guide to all medical units.

A Guide for Medical Units

Briefly the following rules were laid down:

1. An open pneumothorax should be temporarily closed by suture at the earliest opportunity, either at the field ambulance or C.C.S. If suturing is impossible the wound should be packed and strapped to render it airtight.

2. Extensive parietal wounds, including the above, should be treated as any other large wound, and comminuted rib fragments removed.

3. A large foreign body shown by radiographs to be accessible should be removed, haemothorax evacuated, and the chest closed. Bullets or small fragments may be left.

4. Any large haemothorax attended by persistent respiratory distress should be aspirated; this is best done after a lapse of forty-eight hours.

5. Gross infections may be treated by rib resection and drainage. Mild infection may be closed after thorough cleansing of the pleural cavity.

6. Set operations should not be performed until initial collapse has passed off.

7. Always close a wound of the diaphragm discovered at a thoracotomy.

8. Any case subjected to open thoracotomy must be retained for ten days after operation.

9. Reliable *x*-ray plant and immediate access to a pathological laboratory are essential to successful chest surgery.

These rules made a great change in the number of cases left to expectant treatment. Gask estimated that perhaps 25% of cases needed surgical treatment in the first twenty-four hours; even through-and-through rifle-bullet wounds often become septic. Captain Mann of No. 3 Canadian C.C.S. (with whom I worked for a short time in 1917) noted that septic empyemata were not more common with retained missiles than with through-and-through wounds, and that fragments of high-explosive missiles showed only a slighter tendency to become septic than did rifle bullets. Of cases with retained foreign bodies (10% bullet, 90% shell) 16% developed septic haemothorax at the C.C.S. (11% bullet, 89% shell). Of cases without retained foreign bodies (39.5% bullet, 60.5% shell) 21% developed septic haemothorax (20% bullet, 80% shell). The determining factor seemed to be the character of the wound rather than the nature of the missile. Injuries to ribs and laceration of soft parts were mainly responsible for the production of sepsis.

So it came about that the proportion of cases that would from choice (not military necessity) be left to expectant treatment was small. The idea that "closed wounds" as a whole class do not need surgery is dangerous. This is especially true of "stove-in chests" with several ribs smashed and driven in without any penetrating wound. These are veritable "closed wounds," but it was universally agreed that they required immediate operation.

During the summer of 1917 Major Lockwood (of Toronto) and I had the good fortune to be so stationed at Zuydcoote, near Dunkirk, that we received our chest cases direct from the line. They came to us at No. 36 C.C.S. without stopping at a field ambulance. The Passchendaele battle did not affect us, except that no ambulance trains could be spared to take our cases to the base, so we kept our patients through to convalescence. In parenthesis I may remark that we shared the vast sanatorium at Zuydcoote with the French Mobile Surgical Unit 21, of which Prof. Duval was the chief surgeon. We worked there from August to November, 1917. The total number of "G.S.W. chest" admitted was 168; operations were performed on 82, and non-operated cases amounted to 86. Of the non-operated cases 9 were brought in dead, 21 died within a few hours of admission, yet 55 survived. It appears that we refrained deliberately from operation in only 56 cases. As I look through the fatal non-operated cases I think No. 48 is the only one upon which we decided of free choice not to operate. The results of this group of cases turned the scale in favour of early operation rather than early evacuation to the base.

I have one other set of figures of Lockwood's and mine. In September, 1916, 203 cases were admitted to a special chest ward at Heilly. Of these only 16 died in the C.C.S., but this low death rate is partly explained by the fact that abdomino-thoracic injuries were taken into surgical wards and classified separately. I do not know what was the after-history of the 187 cases evacuated to the base; but of the 168 cases at Zuydcoote 113 lived and were discharged by us convalescent. Lockwood noted in his paper that the figures showed a high percentage of recoveries in cases that previously showed a mortality of nearly 100%.

I lay stress on this experience because it shows how few cases a physician will choose to treat expectantly. Perhaps the prophylactic use of sulphanilamide may justify a change in practice.

Classification of Cases

It comes to this, then: there were very few "G.S.W. chest" that, in the climate and soil conditions of France and Flanders, a physician would choose for expectant treatment. But circumstances may compel expectant treatment—for example, the absence of surgical facilities or, even with these facilities, the absence of radiographic facilities; or the patient may be unfit for operation owing to the severity of the intrathoracic injuries, the severity of external or complicating wounds, loss of blood, or collapse or shock due to cold or transport. Allowing, however, for such considerations, there remain two classes of "closed wound" which the physician may be allowed to look after: (1) the cases in which no operation has been deemed necessary and the patient's condition is good; (2) the cases

a which operation has been performed and in which the eon has closed the chest. No physician without rience of war surgery of chest wounds is competent to t cases for Group 1.

Early Aspiration

he whole plan of treatment of closed wounds may be marized in a short sentence: No fluid, whether blood, m, or pus, must be allowed to collect in the chest ly and frequent aspiration must be resorted to whether acotomy has been performed or not.

s a rule it is injudicious to aspirate for either pneumo- ax or haemothorax immediately after the wounding. sionally it is obvious from the urgency of the dys- ea that relief might be obtained by immediate aspira- . Sometimes this becomes evident after resuscitation been tried without success or with only partial success. patient recovers partially from his shock and, as he vers, dyspnoea, which is often absent while the respira- s are feeble and shallow, begins to show itself. It is ortant to recognize that urgent dyspnoea with cyanosis t after wounding is more pronounced in cases of exten- collapse or deflation of the lung without much mothorax or pneumothorax than in cases in which the er conditions are unaccompanied by collapse of the tively uninjured lungs. A useful point in diagnosis is t haemothorax or pneumothorax pushes the heart away, reas collapsed lung pulls it.

he post-operative aspiration of a chest must conform the one rule that no fluid must be allowed to collect in pleural cavity. Looking back at Lockwood's cases I l it was the rule that a chest closed at operation was lored eighteen hours later. Exploration was usually eated several times. Cultures were made, but the dis- ery of pyogenic organisms or pus did not mean that chest was reopened and drained. We always tried eated aspiration. Lockwood's comment on this point s: "The rapid recovery by aspiration from an empyema cted by aerobes and anaerobes demonstrates that eated aspiration should be resorted to before con- ering resection and drainage. The mortality of the er-operation in chest wounds at C.C.S. is nearly 50%." kwood's rules should be adhered to.

"Chest cases should be nursed in the open air if possible Aspiration is carried out as a routine eighteen hours after peration and at the end of the third day. Exploration of he chest is performed at frequent intervals whenever an ccumulation of even small quantities of fluid is suspected. uid fluid, if found, is removed by aspiration. Fluid must ot be allowed to collect after operation. Physical signs are misleading, and nothing but repeated use of the exploring yringe and aspirator, aided by x-ray examination, will keep a chest safely emptied of fluid. Non-operated cases should be treated precisely as post-operative cases."

It is noteworthy that open drainage did not come into s scheme.

We did not recognize in the war of 1914-18 a separate ass of "blast injuries" of the lung such as has been scribed amongst the air-raid casualties of the present ar, and I have not seen enough examples to express any inion about such injuries. It must be realized that the ctims of air raids reach hospital alive with injuries to ich a soldier succumbs on the battlefield, and we know at 50% of all chest wounds resulted in death on the attlefield in the last war. *No one knows whether* "blast juries" contributed to these deaths.

The Physician's Place in a Chest Team

Now I want to say something about the physician's place a chest team, because there is always a definite place r a physician. One of his first duties is to decide as to e intrathoracic injuries in the following way: Is there a sufficient degree of pneumothorax, haemothorax, collapse of lung, laceration or haematoma of lung, injury to heart, pericardium, or great vessels, injury to diaphragm and abdominal viscera, or injury to vertebrae or spinal cord to account for the severity of the symptoms?

Radioscopy and radiography are indispensable in order to reach a correct conclusion on these points. If the patient is unfit to undergo immediate x-ray examination the decision is easier. He is unfit for any immediate operation save one of the following: immediate and rapid operation for the arrest of visible haemorrhage from the chest wall or thorax; arrest of haemorrhage from coexisting wounds, aspiration for relief of pneumothorax (usually valve pneumothorax); aspiration for relief of haemothorax, temporary closure of open pneumothorax.

Duval pointed out the immense value of blood-pressure observations in the differentiation of shock from haemorrhage. The patient must be kept warm and every half-hour the blood pressure be gauged by the sphygmomanometer. In cases of pulmonary haemorrhage great care must be taken not to lower the head and not to administer subcutaneous or intravenous injections. If the blood pressure progressively falls operation is indicated, as haemorrhage is outweighing shock. It must be realized that a patient with a simple through-and-through wound or one with a small missile retained should not be profoundly collapsed or in great respiratory distress after being kept warm and at rest for an hour or two. If at the end of this time the condition has not improved the following possible causes must be considered in addition to the intrathoracic lesions just mentioned: haemorrhage, severe parietal and external thoracic injuries, diaphragmatic and abdominal injuries, and multiple wounds other than abdomino-thoracic.

Haemorrhage

This may have been very large in amount, and there may still be active bleeding As a rule with closed thorax the amount of intrathoracic haemorrhage will not of itself be enough to produce severe shock. When there is an "open thorax" the estimated size of the haemothorax is no guide to the quantity of blood lost, as the greater part of the bleeding may have been external. In such a case physical examination is of little assistance beyond determining that there is an "open thorax" and that the patient is suffering from loss of blood. If the missile has been retained it is of the greatest importance to locate it accurately by radiographs. Signs of increasing effusion after twenty-four to thirty-six hours are scarcely ever due to active haemorrhage. Lockwood and I saw only 5 cases of recurrent haemorrhage.

Severe Parietal and External Thoracic Injuries

Comminuted fractures of ribs, scapula, or sternum produce the gravest symptoms even in the absence of severe intrathoracic injuries. It is of the utmost importance in such cases to determine the extent of the intrathoracic or pulmonary injury. Physical examination by auscultation and percussion is difficult to perform and more difficult to interpret. It will give little information beyond establishing the presence or absence of haemothorax or pneumothorax. But it is essential for the surgeon to know beforehand whether his operation should be limited to the parietes or should extend to the interior of the thorax. As a general rule, if the entrance wound is small and clean and there is no comminution of bone, whilst the extensive bony injury is confined to the exit wound, there will be no in-driven fragments, and the operation may be limited to the parietes. But if the entrance wound is large, if there are in-driven fragments of bone or pieces of clothing, and especially if a large missile is retained, the operation must extend to the interior of the chest.

Associated Injuries

Careful attention has always to be paid to injuries other than purely thoracic which may have been caused by the missile or missiles which have struck the chest, particularly injuries of the diaphragm and abdominal viscera. A prompt decision must be made as to whether there is sufficient thoracic injury to produce the symptoms or whether the thoracic injury may be ignored and a further explanation be looked for below the diaphragm. To the surgeon a definite and reliable opinion expressed by the physician that the intrathoracic injury is negligible is of great assistance. In order to form a definite opinion in such a case, physical examination of the chest becomes more important than in the class of case previously considered. If the heart is not displaced; if there is no great degree of surgical emphysema; if there is no large amount of air or fluid in the chest; but, above all, if there is a fair degree of air entry into the lungs, it may be assumed that, although the missile has entered the chest, the grave lesion exists elsewhere. In a through-and-through wound the track of the missile may make it obvious that no important structure has intervened; failing this, radiographs will be required unless the presence of an abdominal injury is made clear by other signs and symptoms. Abdominal rigidity and immobility are not by themselves clear indications of abdominal injury; these signs are often present in pure chest injuries. Increased dullness in the spleen area, haematuria, the presence of dullness in the flanks, localized tenderness and pain in the abdomen, the peculiar "catchy" breathing suggestive of diaphragmatic injury, and hiccup are signs that should be noted and interpreted as indicating injuries below the diaphragm.

Spinal Injuries and Multiple Wounds

Spinal injuries demand recognition, and not merely those which involve the actual spinal cord. Injuries to the body or processes of vertebrae may cause the gravest symptoms and present very puzzling features. Excessive pain, radiating very irregularly, is constantly met with in injuries of the vertebral bodies, and resembles the intense and erratic pain due to erosion of the vertebrae by aneurysm. Profound collapse which resists all efforts at resuscitation is often seen in spinal injuries, even when the cord is undamaged.

Apart from the associated injuries which the missile entering the chest may have produced, there may be other wounds that make it difficult to decide whether the patient's serious condition is attributable mainly to the chest wound or not. Here, again, if there is fair air entry into the lungs, the intrathoracic injury may be put on one side. A patient with one lung expanding well should not be greatly distressed even though the other lung is completely out of action, provided some hours have elapsed to allow him to adjust himself to his new conditions, and provided he has been kept at rest.

Mr. Thomas Johnston, M.P., Secretary of State for Scotland, has urged Scottish local authorities to improve their schemes for the relief of people rendered homeless by enemy attack. In a memorandum issued by the Department of Health for Scotland the authorities are instructed to make certain that their plans will actually work even in the severest conditions. The rest centre and billeting organization in each area ought to be so efficient that the local authority will be able to deal with its own homeless no matter how severe the raid may be. The Secretary of State is convinced that while much preparatory work has been done by local authorities the relief scheme can be still further improved He attaches the greatest importance to the testing of emergency relief organizations, and urges every local authority to arrange rehearsals on as large a scale as possible.

MEDICAL PLANNING RESEARCH

MANIFESTO BY THE "YOUNGER HALF"

The following letter, signed by forty-eight members of the me profession, has been received for publication.

SIR,—The nature of the war has made it clear that a siderable degree of peacetime reconstruction of all kinds be inevitable, and the Government have already recognized by the appointment of a Cabinet Minister to inquire into s of its aspects. Medicine will unquestionably be affected, we feel that serious consideration should be given now t future needs. There are many signs that the younger doc in the country appreciate this, and it is our aim to collect co-ordinate their thoughts so that they can be, clearly st at the proper time. We are aware that the B.M.A. have se a Planning Commission, and other bodies have set up c mittees with similar purpose, but we feel that there nee no conflict. While we wish to emphasize the views of younger half of the profession, we also hope to enlist sympathy of many of our seniors, and will welcome t support and criticism.

Three Guiding Principles

We therefore invite all who agree with our guiding princ to join us. Our principles are three:

1. In assessing the past, and in planning the future, will proceed by scientific methods. We will collect all a able evidence, we will believe according to the evidence, we will admit ourselves wrong whenever we are shown t so by the evidence. So far as is humanly possible, we examine all proposals (and the evidence on which they based) without prejudice. We will give to tradition custom their due weight, but not more than their due wei and we will not disregard a thing merely because it is nor regard a thing merely because it is new. By so d we hope to avoid unseemly squabbling and makeshift c promise, and at the same time achieve a high degre unanimity.

2. We regard committees, congresses, and meetings valuable for exchanging ideas, but of much less value scientific research, executive work, or practical planning. decision is reinforced by the practical difficulties of graphy and transport, which make such meetings impos at the present time. Our proposed plan of campaign, lined below, enables all who care to do so, including doc serving in the Forces at home or abroad, to express t considered views, and the reasons behind their views.

3. The first consideration of all planning and propc must be the maximum benefit of the maximum numbe patients. The second consideration must be the condit of work of those who serve the patients (doctors, nu lay administrators, almoners, technicians, etc.). Where t two clash, the first must have precedence. But, unless t are considered, the first will be nullified.

Since we wish to press our claims on their merits as object scientific, and practical proposals rather than as having backing of so many thousands of supporters, we invite those who are prepared to co-operate *actively* to join in research. Co-operation can take either or both of two fo We give below a list of subjects which we propose to consi Any member may choose one or more of these subjects prepare a draft report (giving a summary of the present si tion, together with his proposals for the future). The t allowed for this preliminary drafting will be three mon It is hoped to have at least three *drafting members* reporting each subject, and on the major subjects considerably m When the drafts on each subject have been received, they be collated, and a single "preliminary" report prepared. work of collating will be carried out by an editorial gr composed of the signatories of this letter and any who volunteer to join them. Each of these preliminary rep will be submitted to *all* members for comment and critici The criticisms and comments will be studied, and wherever t are an improvement on the preliminary reports they will embodied. Thus a series of final reports will be prepared, we hope to issue these as a book. When this stage is reac our task will be ended.

Ordinary or critical membership is open to all. is intended that in most cases drafting membership be for any doctor or dentist who has been quali less than twenty-one years, or for any final-year medi student, nurse, lay administrator, almoner, dispenser, h pital technician, or other person interested in or c nected with our health services who is not over 45 ye

age. The membership fee in either case is 10s. 6d. This is essary to cover clerical costs and postage, further, we believe at those who have something worth saying will think it worth le to pay 10s. 6d. to say it, and that those who have t will not. Prospective members should send their subscrips to Dr. Kenneth Perry the Connaught Hospital, Walmstow, London, E 17. Critical members must bear in mind at they can anticipate nothing beyond a receipt for at least months only then will the first preliminary reports be ady. All members should keep Dr Perry informed of anges of address.

Drafting members should name their subject or subjects at e time of paying their subscriptions. They will then receive neral matching orders and suggestions—which, of course ey will be fully at liberty to disregard. In general we will k them to pursue the scientific method of collecting evidence d basing their conclusions upon it. In this connexion we ve recommend the P E P report of 1937, or in shorter form e summary by S. Mervyn Herbert, *Britain's Health* (Pelican 4).

The subdivisions of our problem which we propose and from ich we invite our drafting members to take their pick are as follows:

General Problems

The Medical Needs of the Population.—The post-war population—the distribution of the population—the population's needs in terms of doctors (general practitioners, consultants specialists, research workers, public health workers); dentists, nurses, almoners and social workers, clinics, hospital beds, environmental services, nutritional services.

The Capacity of the Population to Pay for its Needs.—The national income—the proportion spent on the health services—how it is collected—how it is spent—the individual capacity to pay. The proportions of the population in different income groups. Family budgets.

How should the Population Pay?—The patient's point of view: cash payment, insurance, rates, taxes. The doctor's point of view, fees, capitation fees, salaries for G.P.s, consultants and specialists, hospital staff, public health workers. Grading of patients on capacity to pay.

How should the Population be Served?—General practitioners—free choice of doctor—clinics—health centres—small hospitals—large hospitals—hospital groups.

How should the Services be Distributed?—Chance—tradition—planning—local authorities—regional authorities.

Administration.—The need for individual autonomy—the need for local autonomy—team work—the firm in general practice—the firm in hospital—medical and lay administrators. Committees: advisory and executive—small and large, medical and lay. Authorities: local, regional, national. Forms and red tape.

Special Problems

The Hospital Services.—Regionalization—unification of control—unification of finance—regional hospital authorities—local hospital authorities—size of hospitals—nursing homes—dispensaries—hospital groups—town or country hospitals—design of hospitals—preservation of traditional features (names of hospitals wards, etc.)—special hospitals, as part of hospital groups, as national specialist centres of teaching and research—out-patient services—appointments for out-patients—clinics—emergency services—the non-urgent patient; waiting lists—attendance services—medical superintendent or firms and units—resident medical officers and resident surgical officers—medical or lay administrators—hospital committees, lay, medical—internal administration of hospitals—consultant and specialist services, in hospital, in the home; "consultoids," "Harley Street"—the "private patient"—medical staff, part-time, honorary—resident medical staff—continuity of treatment—hospital records—clerical assistance for medical staff.

The Specialist Services.—The apportioning of beds according to the needs of the patients—need for flexibility within hospital services according to changing needs of the population—general medicine—general physicians or special physicians—diseases of the chest—tuberculosis services: tuberculosis officers; sanatoria; Papworth; the employment of the tuberculous in sanatoria—cardiology; cardiac invalidism—gastro-enterology—biochemical medicine—neuropsychiatric services, neurology, psychiatry, psychotherapy, occupational therapy, child psychiatry and child guidance, institutional treatment, neuropsychiatric clinics, mental hospitals, institutions for defectives, epileptic colonies, prisons and criminal psychopathic hospitals, the case for a combined service with periods of work in each type of institution, the psychopath at large—arthritic services, physiotherapy, hydrotherapy, spas—fever services—paediatric services—school medical services—venereal services—dermatological services—tropical diseases—convalescence—rehabilitation—the chronic sick—general surgery—general surgeons or special surgeons—anaesthesia—*cancer service*—traumatic surgery, fracture services—burns—orthopaedics—care of the crippled and permanently incapacitated—plastic surgery—massage and physiotherapy—pulmonary surgery—cardiac surgery—abdominal surgery—genito-urinary surgery—cranial surgery—ear, nose, and throat surgery; tonsils and adenoids; the deaf and dumb—ophthalmology; spectacles; opticians; the blind—gynaecology—midwifery; institutional; domiciliary; the midwife—maternity and child welfare services—abortion—birth control—sterilization—euthanasia—eugenics—radiology, who should interpret x rays?—radiotherapy, radium, radiographers—pathology, bacteriology, biochemistry, clinical pathology, laboratory technicians, transfusion services—dentistry, as a part of a national health service, internal problems—pharmaceutics dispensers cash chemists, manufacturing chemists, patent medicines.

Medical Education.—The supply of students—cost of medical training—pre-clinical studies—clinical studies—social studies—environmental studies—apprenticeship in practice—examinations, multiplicity bookishness, cramming—postgraduate training—refresher courses—foreign travel—mixed and unisexual medical schools—university hospitals—research—the film in medical education.

General Practice.—Single-handed or firm—the locum—the assistant—sale of practices—pensions for G.P.s—scope of general practice—need for consultants—pathology in general practice—G.P. specialists—G.P.s and hospitals—the panel and its extension—number of patients per doctor—certificates—dispensing—the panel from the patient's point of view; sickness benefit additional benefits, approved societies—contract practice—clubs—workmen's compensation—domestic help for the sick—should the G.P.s run the clinics?—co-ordination of G.P.s panel committees, regional medical officers—special war problems, shelter doctors, evacuees.

The Environmental Health Services.—Local authorities or regional authorities—duties of the M.O.H.—size of M.O.H.'s area—sanitation rural problems; water supply; refuse disposal—food, protection, nutrition, school meals—epidemiology—vital statistics—port health authorities—industrial medicine—hours of work—holidays—unemployment and health—health education—physical education—medico-legal services, coroners, medical witnesses medical assessors, need for an institute of forensic medicine.

Medicine and the Defence Services.—R.N. Medical Service—R.A.M.C.—R.A.F. Medical Service—Ministry of Pensions Medical Service—I.M.S.—Colonial medical services—Merchant Naval medical services—the case for a combined service with periodical work in each.

The Nursing Services.—Recruitment—training—payment—pensions—domiciliary nursing, the district nurse, the private nurse—*health visitors*—*specialized nursing, fevers, tuberculosis,* the chronic sick, mental nursing, midwives, industrial nurses—seasonal features of nursing, need for a pool of nurses—the male nurse.

The Almoner and Social Services.—Recruitment—training—payment—pensions—scope of work—specialized social work, mental health, family visiting, social research.

Miscellaneous Problems.—The Emergency Medical Service—the State's liability in war—ancillary medical services: opticians; masseurs; chiropodists; laboratory technicians, etc.—special problems of medical research, "pure" research, clinical research, social research, attempts to combine teaching, administration, and research—health services in other countries—medical missions—Highlands and Islands medical service—Gloucestershire medical services—Nuffield Provincial Hospitals Trust—Pioneer Health Centre, Peckham.

The list is a formidable one. With its fifteen main headings and some 320 subject headings, we hope that it is fairly comprehensive. Experience may show that it needs revision, and we are ready to admit errors of omission or commission. There has inevitably been a small amount of overlapping, where the same matter requires consideration from more than one aspect. The list illustrates the size and complexity of the problems which have to be studied; as a corollary it illustrates how essential it is that planning for the future should be done as a large-scale co-operative research rather than as a series of isolated efforts.

It is, of course, open to a drafting member to choose a main heading, or several subject headings. Even if each drafting member undertakes a wide subject or range of subjects, we shall need a large number of such members. If any drafting members also wish to undertake the work of assessing, collating,

and subediting reports, they should indicate this when writing to Dr. Perry.

The signatories of this letter were recruited solely by personal contact. They make no claims to represent the whole profession, and, while they are drawn from as wide a circle as has been possible, there are necessarily many gaps to be filled. They profess no sectional interests.

We are, Sir,

Sidney Abrahams	L. A. Hawkins	Kenneth M. A. Perry

FIRST AID IN AIR RAIDS

EXPERIENCES OF BRISTOL PRACTITIONERS

A very largely attended meeting of the Bristol Division of the British Medical Association was held at the University on June 12, when there was a symposium on "Experiences of First Aid in Air Raids." Dr. J. A. NIXON, chairman of the Division, presided.

Mobile Units

Dr. H. M. GOLDING said that when the sirens first howled in Bristol last year and were followed by bomb explosions the doctors at his post collected with commendable rapidity and presently came back with exciting stories. It was commonplace enough now, though to the speaker the most fearsome part was still the drive alone from home to the post in the middle of a "blitz." In Bristol it had been the policy to place first-aid posts at established clinics or hospitals, thereby ensuring a fully equipped staff. Although he was on the mobile unit he had had a good deal of experience of post work, waiting up all night for casualties which never came, and on other occasions having the post full to overflowing. Shock had been encountered in all its forms, and they had learned that its degree did not depend on the severity of the injury. A patient with a scratch might be profoundly shocked; on the other hand, a man who had been trapped under falling debris was brought in with ruptured patella and forward dislocation of the knee-joint and showed practically no shock at all, although to his injury was added uncertainty as to the fate of his family. On the human side a great deal had been learned. Patients were no longer asked to go home before it had been ascertained that there was a home for them to go to.

The mobile unit was a van fully equipped to set up an emergency first-aid post near the scene of severe "incidents." Unfortunately it had not worked quite so easily. Either there was no suitable accommodation just where it was needed or the building chosen was not blacked out or the black-out had been blasted away. The mobile unit, sent out on orders from the report centre, was manned by a doctor, a trained sister, five auxiliary nurses, and a driver. His own unit had belied its name by remaining completely immobile for many months. The first "incident" attended was a quarter of a mile from any suitable building in which the post could be set up, and the casualties had been collected in a large surface shelter. The casualties varied from a sprained ankle to a depressed fracture of the skull, and they had to be treated under most difficult conditions. It was a great relief to see them taken away in the ambulance.

"In the prevention of shock immediately after injury one was told to ensure freedom from worry, and I had an interesting lesson about that. A woman was completely buried in debris. When her head and shoulders were exposed she cried, 'I have lost my handbag.' A man who was standing by said, 'It's all right, missis, the policeman's got it.' Actually the handbag was not dug out of the ruins until some four later, but the woman had been most effectively treated shock."

Dr. Golding concluded with a special tribute to the si and nurses of his unit, who had turned out in the hazardous conditions without hesitation, and to the p ambulance, and rescue parties, the co-operation between w had been all that could be desired.

Control of the Air-raid Services

Dr. A. M. FRASER (Assistant M.O.H., Bristol) said tha experience had been in the control, where it was his bus to help the divisional report centres in the operation o casualty services. These centres controlled the ambul first-aid, and rescue parties for the division, which also at least one first-aid post, one mobile unit, a bliste cleansing station, and an emergency mortuary. All were co-ordinated by the officer in charge. Reports from wardens were passed to the central control, which was to supply more help where it was needed. The chief of reinforcements from outside was not during the first night, but on the following night should the attack repeated. A second important job was to keep in touch the hospitals. If the control discovered that one hospital receiving a heavy load while others were not rece casualties, instructions were sent to the report centre deflect ambulances accordingly to places where surgeons beds were waiting.

Dr. M. E. J. PACKER said that he had had the privile turning out for every raid, and had learned useful lesso each. On the first occasion, when a factory was "blitz the first-aid unit was called out rather late, and by the it arrived most of the casualties had been cleared away. described certain experiences which showed how necessa was for the doctor attending an "incident" to have e gency equipment with him. He now adopted the pla having a ready-packed bag to be taken wherever nee Any unwanted first-aid vans and personnel should be cle as quickly as possible from the vicinity of an "incide where another explosion might very well occur, disastrous effects. One of the disadvantages of distribu patients in near-by houses in the care of nurses where might receive dressings and injections was that these h were very likely to be deprived of light, and he thoug was important to provide facilities for the antitetanic s injections to be given in the van itself to obviate unneces journeys to the first-aid post. Afterwards, instead of ta the rather cumbersome van to the different points, he le as a kind of headquarters at the main crater and himself round with nurses in a small private car, which turned easily. Dr. Packer mentioned also the greater safet wriggling through narrow holes rather than large, becaus overhanging debris was not so likely to collapse; also danger of the steel helmet knocking against a lot of stuff and precipitating a fall. The doctor should be ac panied by several nurses, who might be left at different po and thus he and they could keep in touch with all "incidents" at the same time.

The Casualty Doctor's Equipment

Dr. J. MORTON EVANS, jun., said that his main diffic in charge of a mobile unit was in getting from the post t casualty. He took three things in his pocket—a torc hypodermic outfit in a spirit case, and a rubber-capped b filled with a solution of morphine, 1/2 gr. per c.cm. It impossible to get sterile water at the scene of an "incide but even in the dark one could push the hypodermic n through the cap and fill the syringe. To give some ou protection to clothes when crawling over debris he custom wore a muffler, an overcoat, an old pair of golf trousers, gauntlet gloves. Of 250 casualties he had attended just one-half had been eye injuries or burns. Many of these firemen who, if not actually burned, had smoke in t eyes to such an extent that for a time they were comple blinded. Washing their eyes out and putting in li paraffin gave them great relief. Of the rest, 7.5% of casualties were burns to the hands or limbs; 10% injuries, 27% wounds of the limbs, 1.5% wounds of trunk, and 3% shock or blast injuries. Of this nur probably 10% were sent to hospital.

r. R. J. STEPHEN spoke also of the large number of burns ting the eyes. He had felt the need for some anaesthetic tion for treating damaged eyes. The usual procedure was sh with an alkaline solution and put in liquid paraffin of the difficulties in treating casualties on the spot was mitting oil of water and electric supplies. Spare water was d in the first-aid van, but it soon became a bowl of mud

r. W. H. HAVES said that he was not attached to the al organization, but had gone to "incidents" near him ped that the scheme for calling upon doctors nearest to ccurrence would soon be completed so that they would alled out instead of going out on their own. On the tion of administration of morphine, it was useless idling about" with ampoules. He thought doctors should upplied with something similar to army field dressings h could be put straight on and bandaged round

r. H. D. PYKE said that there were occasions when he that he had done nothing beyond giving moral support. were he a victim he would like to feel that there was a or handy and that he had equipment ready for use

r. I. G. DAVIES (Deputy M.O.H., Bristol) said that rience had shown that the doctor must be completely ile, with possibly a nurse, and very light emergency ipment. Nobody appeared to have predicted that alties would have to be dug out of buildings amid mbable dirt and dust. First-aid and rescue parties had arn how to dig people out of wreckage without adding to r injuries.

r. N. S. B. VISTER said that in his district outside Bristol ster of doctors had been drawn up for call as needed presence of a doctor was of great help to the first-aid y.

Mobile Units

lonel E. T. POTTS (Ministry of Health) said that mobile s were originally intended for work in rural areas, not in n, but experience had shown that they could be of great e in urban localities. It was useless to call them out, ever, to small "incidents" of three or four casualties ssible to have a roster of doctors who would be ared to go to "incidents" scattered over a considerable so that there would always be medical help available never the need arose. A scheme of that character had been loped in South Wales and in other places whereby a ce summoned the doctor direct and advised the control he had done so. Morphine was originally issued in the of tablets, but the difficulty of dissolving the tablets in dark had been brought to the Ministry's attention, and d now been arranged that first-aid posts and mobile units ld be issued with morphine in solution in rubber-capped les. Among the casualties the large proportion of injuries and and face was noticeable all over the country; next e wounds of the upper extremity, followed by wounds he lower. Burns had increased appreciably since the wide- use of incendiary bombs. Cases of shock were decreas- notwithstanding the greater intensity of air raids.

r. TREVOR JONES (Cardiff) said that Cardiff had taken all ors in active practice who were willing to do the work had attached them to wardens' posts. The doctors were e who lived near the posts and knew the wardens person- When an "incident" occurred the wardens sent diately for the doctors, who were equipped with a bag aining the requisites mentioned, most notably morphine tion and a syringe. Control was notified directly the tor was called out, and thus knew where each doctor was. re were not enough doctors to go round, and sometimes a tor was attached to more than one wardens' post. Senior ical students were also available.

Before this very successful meeting ended it was agreed to d on July 10 a similar symposium on the casualty services r-aid victims in hospitals.

As a result of representations made by the British Hospitals sociation, and pending the conclusion also of definitive rangements, supplies of rationed goods to voluntary hos- ls and other hospitals not covered by existing arrange- nts may be made by traders without coupons against a ipt of the same type as that provided in the case of supplies local authorities.

CENTRES FOR TREATMENT OF FRACTURES

Further centres for the treatment of fractures are to be set up under the Emergency Hospital Scheme in addition to the twenty special Orthopaedic Centres already established. The latter are not able to deal with all types of fracture cases as well as the special orthopaedic cases for which they were designed; and, with the extension of fracture treatment under the Scheme to industrial workers and members of the Civil Defence Services, it has become necessary to arrange facilities at a large number of additional hospitals. The new centres will be grouped as follows:

(1) Fracture Departments "A" in hospitals suitable from their situation for cases requiring treatment over a long period. These departments, which will normally be able to accommodate 100 to 150 patients, will be under the direction of a surgeon experienced in the treatment of fractures, will provide for proper segregation of cases, and will have facilities for massage, electrotherapy, remedial exercises, and occupational therapy.

(2) Fracture Departments "B" in hospitals with the necessary medical staff, experience, and equipment for the treatment of fractures but suitable only for ambulant cases and those not requiring more than about a week's in-patient treatment.

(3) Fracture Clinics "C" within reach of the patient's home for out-patient treatment after discharge from hospital. *Arrangements are being made to recognize certain clinics for this purpose*, and as soon as these are settled details will be sent to hospital authorities

This information is given in a Ministry of Health circular (No. 2395) which has been sent to local and hospital authorities and in some instances to medical officers of health and is accompanied by a list of the Orthopaedic Centres and the hospitals which have been selected as Fracture Departments A and B. Instructions are being issued as to the types of cases which should be transferred to Orthopaedic Centres and to the various fracture departments and, for the benefit of the latter, information concerning personnel, accommodation, and equipment.

INTER RELATION OF MAN AND FUNGUS IN HEALTH AND DISEASE

A Chadwick Lecture on this subject was given on June 19 at the Chelsea Physic Garden, S.W., by Mr. J. Ramsbottom, D.Sc., with Sir William J. Collins, M.D., in the chair. The lecturer began by recalling that the outstanding characteristic of fungi was that they had no green colouring matter—chlorophyll—and were unable to form their own carbohydrates from the carbon dioxide of the air and water as did green plants. They must therefore have organic food already elaborated and thus must live a parasitic or a saprophytic existence. Apart from the use of some of the larger fungi as food and the poisonous properties of a few of them there were many ways in which fungi affected the welfare of man. He himself might be parasitized by ringworm fungi of various kinds or by more obscure but more virulent forms; his ox and his ass might likewise suffer from similar diseases. Fungi levied a constant and sometimes disastrous toll on his crops, and the fruit he grew was rarely without spot or blemish unless precaution was taken against attack. The larger fungi often killed forest trees, or produced a "wet rot" which would cause structural defects if the timber was used haphazard. Moreover, all fallen logs, leaves, herbs, grasses, and other organic material were gradually removed by fungi. Without saprophytic organisms acting in this way the surface of the earth would soon become so covered with remains that seedlings would be unable to take root or obtain food, and vegetation—and life as we knew it—would end. But if man wished to preserve anything organic for his own use he must wage constant war against fungi. If his buildings were not kept dry and well ventilated the woodwork was almost invariably attacked by the dreaded dry-rot fungus, *Merulius lacrimans*. His stored food must be dry, or sterilized, or kept at a low temperature, otherwise it would rot and putrefy. But all fungal action was not to man's disadvantage. Every nation had its fermented liquors; yeasts raised the dough in breadmaking; moulds ripened cheese. Modern practice was to control the age-long methods, for otherwise there might result products other than those traditionally

anticipated. Man, moreover, was beginning to harness fungi to carry out processes according to his wish. Taka diastase, used so much in medicine, was produced by the same fungus which fermented soy sauce, the basis of all table sauces. In spite of Italy's being at war there was abundant citric acid, for it was easier to produce this by mould fermentation than to extract it from lemons. Just as man depends on green plants for his existence and developed them for his enjoyment so he depends equally on saprophytic fungi and was using them in increasing measure for his benefit.

HOSPITALS AND GAS CASUALTIES

NOTES ON RECEPTION AND MANAGEMENT

Should the enemy employ gas the medical services would inevitably be heavily taxed and the hospitals would be confronted with a number of new problems, both clinical and administrative. Some of these must remain unforeseen. For others, past experience and various sources of information provide a solution. As with bombing, so with gassing: modifications of plan and method in respect of the collection, transport, hospital treatment, and evacuation of casualties would evolve from experience derived in new situations. In the meantime it must be considered urgently necessary to establish in every suitable hospital in the country a state of preparedness for such contingencies as can at present be anticipated. Such preparedness demands thought and action and training, but need not involve any undue elaboration or expenditure. Much information and much instruction have already been issued on decontamination and the treatment of the individual case. Outside the hospitals training and preparation should by now be well advanced. The present notes relate to organization within the hospital.

Medical Officers in Charge of Gas Casualties

In every hospital capable of receiving casualties there should be at least one physician whose duty it would be to take charge of the reception, sorting, and care of gas cases. From the available manuals and other literature, and attendance at lectures or courses, he should make himself acquainted with the essentials of diagnosis and treatment. He should hold himself responsible for the instruction of house officers, sisters, nurses, and orderlies, and, in the teaching hospitals, of students, in the methods of treatment advocated for casualties due both to the vesicant and to the pulmonary irritant gases: where staff is short the co-operation of dental surgeons for assistance with oxygen therapy and apparatus could also be sought. In conjunction with the medical superintendent or medical officer in charge, he should ensure the arrangement and equipment of the hospital decontamination centre. He should personally supervise the training of a decontamination unit (male and female). In conjunction with the medical superintendent or medical officer in charge he should acquaint himself with the storage, source, and reserve sources of supply of oxygen cylinders. He should procure or improvise* sets of apparatus for the distribution of oxygen from one cylinder to several patients. He should ensure that all those likely to be concerned understand the use of the nasal catheter, the B.L.B. mask, the spectacle-frame outfit, and fine-adjustment valves and flowmeters, and that there is a sufficient supply of all of these and of rubber connexion tubing and glass connexions.

Organization

As with wounds, so with gas casualties: "reception and management" may be held to cover decisions in relation to (a) the initial reception and sorting of cases; (b) the grouping or separation of cases into categories for special treatments; (c) the disposal of cases, including suitability and optimum time for transportation elsewhere of special types of case. Such decisions clearly require different consideration and arrangements in the case of vesicant and pulmonary irritant casualties.

* A note on inexpensive improvised distribution will be issued later.

Reception and Management of Casualties due to Vesicant

Although every hospital should have its decontami centre and a trained decontamination unit it should not, good co-operation on the part of the public, the A.R.I vices, the first-aid posts and cleansing centres, be called to deal with the generality of mildly or moderately taminated cases. It should, however, expect to handl severely contaminated cases (liquid) or persons who hav recently contaminated (liquid or vapour) when withou mask or otherwise inadequately protected; (b) cas simultaneous wounding and gassing; (c) its own per who have been exposed in or in the neighbourhood hospital. Of such cases, once decontaminated and in r of initial treatment for skin and eyes, it should be pc (when necessary) to evacuate the majority as stretch sitting cases forthwith or at an early date, excepting those whose associated wounds are of such severity as t clude movement.

During the hours or days following a local gas attack probable that cases other than those in the above cate would begin to arrive for treatment of developed le Minor skin and eye cases could be treated as out-patien if desirable on other grounds, evacuated. Admission be necessary for cases of severe or extensive skin lesion which a good supply of cradles is necessary. Again, hov the evacuation of most of these, excepting the more s broncho-pulmonary cases, should generally be justifi Cases in the above categories would be in a stage past in which further decontamination by washing would be sary or, in fact, of any value. In the case of persons rec gassed and suffering from wounds and wound shock, d tamination should not go beyond careful undressing with use of scissors, attention to exposed parts, initial treat of the eyes, and cropping of hair if liquid contaminati suspected. Once undressed and so treated, patients wou longer present any dangers to those working in the oper theatres or to other patients or personnel in a ward.

Casualties due to Pulmonary Irritant Gases

Phosgene casualties on or soon after arrival may be veniently sorted into (a) mild, (b) moderate, and (c) s categories. The "mild" cases (perhaps 50% or more o admissions) may present with such symptoms as cough tightness or pain in the chest, but with good colour, the rate and quality not greatly or at all disturbed, little dyspnoea, no cyanosis, and no physical signs of pulm oedema. Such cases should be treated in a separate ward the weather permits and war conditions are no contraindica in tents or marquees, on balconies, or otherwise in the They can be nursed on stretchers if beds are not avail They should not be allowed to exert themselves or to ge they may be given fluid nourishment as required and sedatives.

The "moderate" cases will show the same sympton more severe degree, with the addition of more "tightne the chest," dyspnoea, and perhaps slight forms of cya They can be similarly treated, and may be further ben by the administration, for a few minutes at a time quarter of an hour, of pure oxygen from an ordinary ni oxide bag with small, easily movable cylinders. In this one nurse or orderly can take charge of some dozen c Once a sufficient improvement is manifest, oxygen the can be discontinued. Should any case, on the other h deteriorate in spite of these measures, continuous ox therapy must be immediately instituted.

The "severe" cases (perhaps 20% or less of the admissi show urgent dyspnoea. Blue or grey cyanosis may be pr or appear, often with auscultatory signs of pulmonary oe or with actual expulsion of froth from mouth or nose. T may be collapse, with feeble pulse, low blood pressure, cold extremities. The cases should be treated from the with continuous oxygen given in sufficient quantity to m tain a pink colour. It may be necessary to continue treatment for twenty-four, forty-eight, or even seventy hours. The closest watch must be kept on such cases an the efficiency of the cylinders and oxygen-feeding appar It may be necessary to raise the feet and lower the hea facilitate the escape of oedema fluid. Ideally, no patient

known to have been exposed to phosgene gas or who sents indisputable symptoms should be evacuated to a ance or otherwise than as a stretcher case for a period of ty-eight hours. Exertion may bring on serious symptoms a patient previously but little affected. No case requiring inuous oxygen is likely to be fit for evacuation in under eek. Absolute rest, fresh air, oxygen, posture, adequate ds, and good nursing are the essentials of treatment. The egation of the severe from the mild cases is important m the psychological point of view as well as to ensure xtive supervision and treatment.

There should be a weekly "drill" in reception, decontamination, and oxygen therapy, employing personnel as atients."

All hospital personnel should be instructed to keep their s-masks near their place of work. On one day in each week personnel should wear and work in their gas-masks for a ater of an hour. They should also carry A.G. No. 2 ument with their masks.

AWARD FOR GALLANTRY IN CIVIL DEFENCE

e award of the George Medal to Dr. LAURA BATEMAN, dical officer, Brook Hospital, Shooter's Hill, is announced a *Supplement* to the *London Gazette* dated June 13. The announcement reads as follows: "When the Brook spital was bombed two maids were imprisoned by debris. Bateman quickly relieved the suffering of the first maid. the other was buried under girders and masonry. Dr. teman volunteered to crawl under the wreckage and minister an anæsthetic. A porter held her, suspended by r ankles, while she reached the casualty and successfully ried out the injection. A slight subsidence might have sulted in her being trapped and fatally crushed. The nger was very apparent, but this did not deter Dr. Bateman m carrying out a gallant and difficult action."

ROCKEFELLER MEDICAL STUDENTSHIPS

the *Journal* of March 15 (p. 368) we announced the facilis generously offered by the Rockefeller Foundation for itish medical students to pursue clinical studies in medical hools in the United States and Canada. The composition as given of the British committee formed (with Sir John xford as chairman) to select between twenty and thirty idents from among those nominated by the deans of medical hools in this country. Nearly a hundred applications were ceived and about two-thirds of the candidates were interwed. The following are the names of those chosen by the lection committee for Rockefeller medical studentships. These enty-six students are being sent to nineteen universities in e U.S.A. and Canada.

Name	*University Medical School*
BAINBRIDGE, J.	Oxford
BARTLEY, C. W.	London Hospital
BEAZAN, E. F. B.	Liverpool
DAVIES, J.	Leeds

Reports of Societies

DERMATOLOGY IN MILITARY PRACTICE

In an address delivered to the North of England Branch of the British Medical Association at Newcastle-upon-Tyne Major R. M. B. MACKENNA, Command Specialist in Dermatology, Northern Command, discussed a number of points in practical dermatology which had arisen in his Army experience.

Major MacKenna said that a reference to the Official History (1923) of the last war showed that, with the exception of pediculosis corporis, the cutaneous diseases which then caused most absence from duty were those most prevalent in the Home Army to-day. Scabies with its septic complications, infected (impetiginized) seborrhoeic eczema, impetigo contagiosa, ecthyma and furunculosis all had a high incidence in the last war and had engaged attention during the present one; but the group of diseases classified as "inflammation of connective tissue," including abscesses, boils, pyodermia, and the like, had not been so prevalent as in peacetime. The incidence of diseases such as *moniliasis* and *plantar warts* had been low.

Treatment of Scabies

In the 102nd Field Ambulance during the last war scabies was treated by means of a solution of sodium thiosulphate and a dilute mineral acid. In recent years this routine had been popularized by Wernick in Germany and Huber in Hungary. It had the advantages of therapeutic efficiency, rapidity of action, and cheapness. After a bath or a wash with hot water a 40% aqueous solution of sodium thiosulphate was applied to the patient, from the neck to the feet, with careful attention to the flexures and the webs between the fingers. The solution having dried, the patient was then swabbed or sprayed with a 5% aqueous solution of hydrochloric acid. A whitish precipitate of sulphur and salt appeared on the skin, which was allowed to dry, and the process was repeated. When the second application of acid had completely dried, the patient put on clean clothing, his former clothing meanwhile being disinfected. The whole process was repeated on the following day. This routine was not advisable with children on account of the coughing and discomfort caused by the liberation of sulphur dioxide.

Another good treatment was Nielsen's ambulatory method. During a hot bath the patient was cleansed thoroughly with soft soap, and while still wet his body and limbs were painted with the following solution, applied with a brush:

℞ Isopropyl alcohol, Benzyl benzoate, Soft soap } āā partes aequales.

When the solution had dried a second application was made, and twenty-four hours later the patient had a cleansing bath.

These were two modern methods of treating scabies, but Major MacKenna had found Marcussen's ointment satisfactory when properly prepared and used with discretion. Two quick baths were given each day. After the second bath, in the afternoon, the ointment was applied from neck to feet. By this technique the incidence of sulphur dermatitis was kept low. The average number of days on which the ointment was applied in 100 consecutive uncomplicated cases was 3.7. There was a similarity between the reaction to sulphur and to ultra-violet rays. The red-haired subject invariably developed sulphur dermatitis after a minimal exposure to sulphur; the brown-haired blonde was more immune, and sulphur dermatitis very seldom developed in the brunette.

Ecthyma

Ecthyma, which was uncommon in civilian practice, gave rise to a good deal of prolonged invalidism during the last war. It usually developed as a complication of scabies or pediculosis corporis, and had been defined as a deep or dermic impetigo, differing only in degree from impetigo contagiosa. These cases had caused him some anxiety in military practice because of their very slow response to treatment. Hot fomentations, kaolin poultices, acriflavine emulsion, eusol compresses, perchloride of mercury lotion, iodine, and starch paste had all been tried, but the ulcers were indolent and intractable. Then he recalled that many authorities believed the condition to be streptococcal in origin, and he tried the effect of giving sulphanilamide or sulphapyridine by mouth, but the response was disappointing. Finally he tried the effect of crushing a tablet of sulphapyridine to fine powder, pouring this into the ulcer, and sealing it in place by means

of a piece of gauze or lint thickly smeared with Lassar's paste. He found this to be a very successful line of treatment, to which few cases of ecthyma failed to respond. The same treatment was quite useful in impetigo contagiosa, particularly in those cases in which the oozing was not too copious; and it was also a very satisfactory treatment of chancroid. It was interesting to find that better results were obtained by the crude method of crushing sulphapyridine tablets to fine powder and using this as a local application than by using powdered sulphanilamide.

Major MacKenna also described a case of chronic meningococcal septicaemia—a condition to which there was a brief reference in the *Medical History of the War* of 1914-18, but which seemed to have been forgotten, except by a few authorities, during the last twenty years. He had come across one case, which seemed to be an almost classical example, in a young officer who had had a sudden rigor followed by a rise of temperature; the fever subsided after a few days, but was followed some weeks later by another rigor, necessitating admission to hospital. For two days he had an intermittent temperature rising to 103°, but beyond this there were no definite symptoms or signs. After ten days, during which clinical investigation was made and no reason for the pyrexia was found, he returned to duty, but had another rigor, and came back to hospital with an intermittent pyrexia which lasted for three days. On investigation the only finding of significance was a leucocytosis of 10,000 cells per c.mm., without alteration of the relative proportions of the leucocytes. A further rigor was associated with the development of reddish nodules on the limbs, swelling in the elbow-joint, and pains in the knee. A blood culture was taken during a period of pyrexia, and meningococci were isolated. In a second case meningococci were again cultured from the blood stream. Each case cleared up under intensive dosage with sulphapyridine (a total amount of about 30 grammes being given), although in the first case, small doses of sulphapyridine had been administered when the patient first came into hospital, but had not cured the disease.

Major MacKenna continued his address with some remarks on sulphapyridine in the treatment of gonorrhoea—a full account of which will be found at page 958 of this issue.

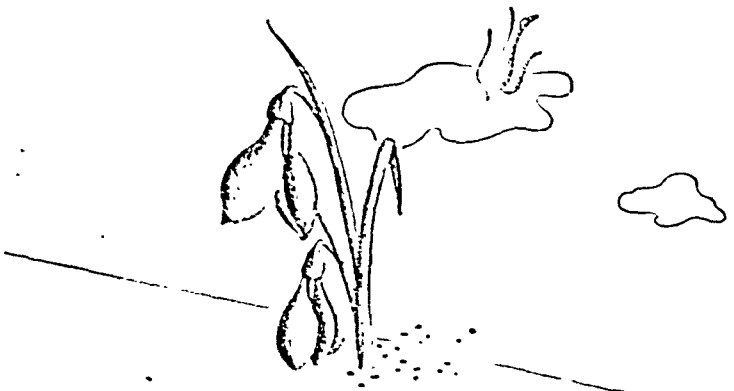
SAFETY IN SURGICAL TREATMENT OF RECTAL CANCER

At a meeting of the Section of Proctology of the Royal Society of Medicine on June 11, with Mr. W. B. GABRIEL in the chair, a discussion took place on the factors which make for safety in the pre-operative and post-operative treatment of carcinoma of the rectum.

Prof E. R. FLINT founded his opening remarks on 86 cases in all of which colostomy was done, but in only 49 subsequent excision of the rectum, giving a proportion of 58% in which he thought excision was justified. Unless surgeons were engaged in special hospitals for dealing with these conditions their operative experience was not likely to be large, therefore the surgical methods in use should be standardized so far as possible from the point of view of the safety of the patient. The excision in all these cases was done according to Kraske's method, which he thought to be safer generally than the abdomino-perineal, except in the hands of surgeons of great experience. Unless there was acute obstruction, patients with carcinoma of the rectum were not extremely bad risks. Nevertheless, operation was a tax upon them, and two pre-operative measures advisable were colostomy and blood transfusion. When faeces were diverted from the affected part, excision was rendered much safer in that the virulence of organisms in the neighbourhood was greatly diminished and the rectum could be cleaned. There was no doubt that after a colostomy had been carried out and given time to function properly the condition of the patient was immensely improved. Blood transfusion was customarily given the day before the operation and if necessary was continued at the time of operation and afterwards. Infection might occur when the gut was cut across, or it might take place subsequently in the form of cystitis. To avoid infection of the wound he divided the colon between clamps, burnt the end which was left, and infolded it in the same way as with a duodenal stump in gastrectomy, taking care that the cut end did not come in contact with the wound. At the end of the operation he put in a three-way Carrel tube through which Dakin solution was syringed, and gauze soaked in Dakin lightly laid against the whole surface. The same purpose might perhaps be serve by powdering the surface with a sulphonamide compound To avoid cystitis, which might be fatal, he irrigated th bladder by the continuous method. Apart from the continue irrigation through the Carrel tube and the continued irrigatio of the bladder there was not very much necessity to d anything further.

Pre-operative Considerations

Surgeon Rear-Admiral GORDON-TAYLOR said that one of th most important pre-operative measures was an early decisio by the surgeon as to the type of operation he proposed fo the particular patient. The surgery of cancer was surgery c the lymphatic system, and for many patients the "com bined" operation would carry a heavy mortality. The nex pre-operative measure of importance was that the surgeo should be skilled, experienced, and judicious. He woul consider the age, sex and race of the patient, also the cardio vascular, nervous, and urinary systems; pulse pressure woul also need consideration as indicative of the type of operatio to be performed. Any surgeon of experience would bewar of the patient who was extremely apprehensive, also of th one who "changed his religion the night before the operation or who kept the theatre waiting while he finished his auto biography." Age offered no barrier: most surgeons woul have performed excision successfully in patients over seventy Women stood the "combined" operation better than men Some races were a bad risk. There was no doubt that pre liminary drainage helped enormously.



Dr. CUTHBERT DUKES indicated certain ways in which th pathologist could help. It had been the practice at St. Mark' to carry out a routine biopsy in all cases, and this ofte afforded important information as to both the growth an the ability of the patients to stand the operation. Of chie importance was the recognition of anaemia and of defectiv renal function. The pathologist could also be of assistanc in post-operative complications.

Mr. NAUNTON MORGAN said that the control of pre- an post-operative fluid balance was essential, and in a majo operation it was necessary to give an additional 500 to 1,00 c.cm. of fluid. A large amount might be lost by vomitin and must be replaced. The giving of fluid by the mouth might be dangerous, and after excision of the rectum fluid should be given by the intravenous route. Bowel activity might be encouraged by the use of small enemata after flatu or faeces were passed; large enemata should not be given, a distension might cause kinking. Everyone would agree tha routine blood transfusion had reduced the mortality rate.

The Anaesthetist's Part

Dr. T. FRANKIS EVANS spoke of the anaesthesia in such cases. He would first see the patient, learn his temperament, gain his confidence, and give him some reassurance. Examination of the heart, arteries, and lungs should be carried out; it was essential to know of any degree of anaemia, and the blood urea was an excellent criterion of general bodily function. Long operations made shock more likely, and the operation of abdomino-perineal excision had been shortened by the simultaneous work of two surgeons. The anaesthetist should choose the type of anaesthetic which would render the surgeon's work as easy as possible. He believed the best results were obtained after preliminary sedation with omnopon and scopolamine, which he used in preference to morphine, followed by the intravenous use of pentothal. This was followed by a spinal anaesthetic—he preferred percaine. After indicating other anaesthetic procedures, the speaker mentioned the necessity for giving fluids intravenously, and not by mouth, to avoid sickness.

Dr. RONALD JARMAN said that the main points of safety to be considered were the condition and comfort of the patient, team work, type of anaesthetic, and after-treatment. The patient should be reassured and allowed to get to know everybody concerned in looking after him. If the surgeons and anaesthetists were used to working together it made for greater speed and safety. There was not much for the anaesthetist to do after the operation, but he should be prepared to give whole blood or solution in glucose, whichever the surgeon thought necessary. He himself had had five deaths out of 500 cases on the table—two from coronary thrombosis, two with fatty heart, and one from shock—and the range of ages was from 27 to 77. The success of the operation turned

CVS-MII

SAFETY IN SURGERY OF RECTAL CANCER

largely on the speed with which it was done. When patients had partly collapsed on the table dramatic recoveries had been seen on giving a pint of whole blood straight away. From the results of his cases, he believed that pentothal intravenously, light paraffin as a spinal, followed by nitrous oxide and oxygen, were the anaesthetics of choice.

Surgical Procedure

Lieut.-Colonel J. A. MACFARLANE, R.C.A.M.C., said that the risk of obstruction before operation was of the greatest importance. He did not agree that there should be a standard operation; each case should be considered on its merits. Patients should be in hospital for at least ten days before operation and put on a diet of non-residue fluids. If there was evidence of chronic obstruction when the abdomen was opened there should be no hesitation about dividing the operation into two stages, changing one's mind and doing a colostomy, and leaving the patient for a further period of two weeks during which the distal loop should be washed out daily. In acute obstruction it was his experience that satisfactory as an immediate procedure carried with it a high mortality, and it was his practice to do a blind caecostomy under a local anaesthetic, which got the patient over the emergency and left time for thorough investigation and planning of the best operation for the type of case.

Mr. LAWRENCE ABEL was interested to find that Col Macfarlane's procedure was so closely parallel with his own. He agreed with what he had said about getting the bowel clean before operation, and his experience was that if the urine was clean the bowel was clean. No patient who had had a laparotomy should be allowed to drink anything at all, and the bowel began to move; water, salt and sugar should be given by the intravenous route. He recommended the use of fractionated rather than distilled water. A point which had not been mentioned was the question of moving the patient: the more ill the patient the more quickly he should be moved out of bed. The average case with tables should be moved out of bed a little over twenty-four hours after operation, if only for a few moments, and on the second day for a longer period, and then remain up for twenty-four hours.

In some further discussion Dr. MOLLISON pleaded for the use of whole blood rather than plasma or serum. Mr. E. T. C. MILLIGAN mentioned factor, which made for speed in operating; Mr. TURNER WARWICK spoke of the importance of guarding against bladder infection; and Mr. DICKSON WRIGHT spoke of the value of dusting the wounds with sulphanilamide powder. In some recent cases he had used a sulphonamide tablet with excellent results. One advantage was that the patient absorbed the substance into the blood stream and primary complications were prevented.

A Comparison between Two Cities

Glasgow and Birmingham are of almost the same population—just over a million—and in an address to the Scottish Branch of the British Hospitals Association recently, Mr. T. W. Place, honorary secretary of the Contributory Schemes Association, used this fact to make a rather telling comparison in favour of contributory schemes. He said that the amount provided to Glasgow hospitals in 1939 was almost the same as that handed to Birmingham hospitals in the year 1926 before the introduction of the contributory scheme—namely, £100,000. But in 1939 the Birmingham hospitals received over £250,000 from the contributory scheme, and in addition paid some £60,000 to hospitals outside the city for treatment given to patients. In 1939 the Glasgow Royal Infirmary received about £34,500 in workers' contributions, plus another £22,000 from general subscribers, whereas in Birmingham the amount handed over to a comparable hospital was £80,000, with another £10,000 from subscribers. The differences were, in his view, an unanswerable case for setting up a contributory scheme in Glasgow. It was mentioned at the same meeting that all the regional committees with the exception of Dundee had approved generally of the proposals for the reorganization of voluntary hospitals, and the scheme was being extended to include hospitals under local authorities.

Incidence of Rheumatism in Scotland

In an address at the annual meeting of the Edinburgh Cripple and Invalid Children's Aid Society, Prof. L. S. P. Davidson said that if some investigations of the incidence of rheumatism in the north-east of Scotland held good for the whole country then 300,000 persons in Scotland went to their doctors annually for treatment for rheumatism of one kind or another. Perhaps 60% or 70% suffered from the simpler forms of muscular rheumatism but a large proportion were very seriously crippled, and from 50,000 to 60,000 persons in Scotland were crippled so completely as to be unable to work for at least sixty days in the year. He drew attention to the inadequacy of hospital treatment available for chronic rheumatic disease. Probably not more than 10% of those suffering from this condition could depend upon adequate institutional facilities.

Local News

SCOTLAND

Tuberculosis Campaign in Scotland

At the recent annual meeting of the Royal Victoria Hospital Tuberculosis Trust, Edinburgh, Prof. Charles M'Neil, who presided, said that when one looked at the figures for tuberculosis it might seem as if the disease had been conquered. That easy optimism was never entertained by the late Sir Robert Philip, who founded the Trust, nor was it entertained by the executive of the Trust to-day. While the family tragedies which once occurred were now rare, the minute seeds of the disease were still sown within the family, and preventive medicine was addressing itself to the early eradication of infection. Sir William Carnegie said that the executive believed that suitably equipped sanatoria ought to be distributed all over Scotland to work in conjunction with the local authorities. In the annual report of the Trust, which was adopted at the meeting, it was urged that statutory recognition should be given to "care work" in Scotland, including measures to assist the patient before he went into hospital, to help his family, and to consolidate his recovery. This was a special field for voluntary organizations to work in liaison with the official services.

ENGLAND AND WALES

The Birmingham United Hospital

The report for 1940 of the Birmingham United Hospital, which includes the General and Queen's and the Queen Elizabeth Hospital, has now been published. When the effects of air bombardment began to be felt the Board decided that the General and Queen's Hospitals should be organized as casualty clearing stations and that the bulk of the normal civilian work should be concentrated at the new hospital. Nearly 600 beds are now constantly in use at the Queen Elizabeth, whose steel fabric and isolated site render it comparatively safe. At the General Hospital, in collaboration with the Ministry of Health, a system of frequent and rapid evacuation has been worked out by which patients are sent to the country as soon as possible after operation or the completion of other necessary treatment. By this means, though less than the half the usual number of beds is available, the General Hospital actually dealt with a larger number of in-patients in 1940 than in 1939, and the number of operations in the various theatres increased by over 5,000 in the year, this increased surgical work being due mainly to accidents in the black-out and in factories. During the year under review air-raid casualties were treated in the United Hospital. It is stated that the work of the first-aid and rescue parties and of the ambulance service in Birmingham has been excellent. The hospitals receive casualties very soon after the bombs have fallen, and the casualties have been handled well and carefully, with no harmful interference. The Board of the United Hospital has therefore decided that, at no matter what cost, it will continue to provide a casualty service in the centre of the city, so that the wounded may be efficiently treated without the delay and discomfort of journeys to other areas. The buildings of both the General and Queen's are old and fragile, and, deeming it necessary to have some premises in reserve, the Board have taken the basement of some business premises for use as an operating theatre, with three

tables, an *x*-ray room, and a sterilizing plant. This emergency hospital is seventeen feet below ground, with seven floors of steel framework above it, and is ventilated by a forced intake of air. The Board has also assumed responsibility for an outlying subsidiary hospital for convalescent patients.

Salaries of London District Medical Officers

The London County Council is revising the salaries of officers of the district medical service. The proposals of the Hospitals and Medical Services Committee provide, with a few exceptions, for a general reduction in salaries and allowances consonant with a general diminution in the work throughout the county of London. In eight districts, however, the work has been found to have increased, and increases of salaries of two district medical officers and six assistant officers appointed to those districts are proposed. Under the Public Assistance Order, 1930, the consent of the Minister of Health must be obtained before the remuneration of a senior Poor Law officer is reduced, and three months' notice of such reduction must be given to the officer concerned. In cases coming within this provision the revised salaries and allowances will operate from September 1 next for one year or until any reorganization of medical relief districts necessitates their revision; in the remaining cases the proposed effective date is July 1. The reductions of salaries apply in seven cases, and in six of these the provisional allowances are wiped out. The provisional allowances granted to twenty-eight district medical officers are reduced, as are the provisional salaries of forty-three assistant medical officers. Some of the reductions are quite considerable: for example, a salary of £300 is reduced to £165, another of £300 to £210; provisional allowances are reduced, in one case from £165 to £55, in another from £225 to £120, in a third from £124 to *nil*. The largest addition to salaries or allowances proposed is from £225 to £310. The proposals are estimated to result in a saving to the Council of just over £5,000 a year.

Correspondence

America and British Science

SIR,—Some of your readers may have seen my letter to the *Times* of June 20, on the generous gifts recently made to the Royal Society by scientific societies of the United States of America—an earlier one of 10,000 dollars from the American Philosophical Society "for the aid of science in Britain," and now, last week, a gift of 5,000 dollars from the American Physiological Society "for the support of scientific publications in Britain, especially in physiology."

A natural and helpful comradeship between medical men of different countries has always been at least as strong among the physiologists as among those whose work is in other branches of medical science or practice. Certainly we British physiologists are on terms of sufficient intimacy with our American colleagues to know well that the American Physiological Society, like our own, depends for existence and support on the efforts and the contributions of members who are working men of science. Their gift will assuredly have a direct importance for the object which they named in making it; but while we gratefully recognize its immediate and intrinsic value, we shall not miss the wider meaning of the fraternal impulse which determined this fine and generous action. We shall be sure that it symbolizes a desire of our American friends to share with us, as far as national policies allow, in the losses which are being encountered in defence of ideals which are theirs as much as ours.

Such gifts, indeed, are among many signs of the fuller understanding which comes with the recognition of a common peril and a common duty. An interchange of medical personnel has begun. The generosity of the Rockefeller Foundation is enabling a chosen batch of students to go to American medical schools; there must certainly be more of such interchange after the war, and in both directions. Qualified American medical volunteers are arriving in this country. Close collaboration in scientific researches more directly concerned with warfare, has for some time been a necessary and well-established condition of America's share in the equipment of our Forces. Surely it is clear that the greatest gain which can come to us, and to the world, from a war in which so much has been and must yet be sacrificed, is this closer and more conscious unity between peoples who have always been bound together, not merely because they speak the same language and share so much of history and tradition, but because their ideals and their outlook on life are, in very truth, essentially identical. To see in the promotion of such unity the best hope for the future, to work for it in every way and to guard it from the weakening effects of sectional aims and factitious differences, seems to be the best acknowledgment that the medical and scientific men of Britain can at present make to the American colleagues who, with a noble and simple generosity, are showing their desire to be identified with our cause.—I am, etc.,

Hampstead, June 22. H. H. DALE.

Crush Injuries

SIR,—In your issue of March 22 there appeared three papers by Bywaters and Beall; Beall, Bywaters, Belsey, and Miles; and by the M.R.C. Subcommittee dealing with crush injuries suffered during air raids that were followed by renal failure and, in many cases, by death from uraemia. A leading article in the same issue drew attention to these so far inexplicable phenomena and called for animal experiments to elucidate them. In these articles the work of E. Andrews of Chicago (*Arch. int. Med.*, 1927, 40, 548) appears to have been overlooked. Andrews worked on renal and metabolic problems of acidosis, which he induced by giving large quantities of hypertonic NaCl solution to dogs intravenously. During these experiments he accidentally tied a limb of a dog too tight to the operating table so that it became oedematous. On releasing the leg and massaging it immediate and complete anuria set in, followed by a rise of blood pressure, nitrogen retention, coma, convulsions, and death. At necropsy oedema of the brain was found, but no renal lesions were present. The experiment was frequently repeated and identical results were obtained. When the suppression of urine was not complete the urine contained albumin and granular and hyaline casts. The author believes that faulty carbohydrate metabolism in the affected limb was responsible for the results. Andrews also observed simultaneously with the anuria a considerable movement of calcium out of the cells in favour of potassium. On this was based an attempt to counteract the process by giving massive intravenous doses of calcium, and thereby he was able to institute immediate diuresis with subsequent recovery of the dog.

All the human cases of crush injury under air-raid conditions can be said to suffer from acidosis induced by starvation and exhaustion. In the paper by Bywaters and Beall a lowered alkali reserve was in fact observed and taken for an indication to stop further saline administration. All the reported cases showed considerable oedema of the crushed extremity. Thus, the parallelism of these cases with the experiments of Andrews appears rather convincing, and his attempt at reversing the condition seems to merit close attention.—I am, etc.,

London, W.1, June 15. G. SCHOENEWALD.

Da Costa's Syndrome

SIR,—Dr. Paul Wood has rendered an important service by the publication of his Goulstonian Lectures. It may be hoped that they will assist medical officers in the Services and members of Ministry of Pensions Medical Boards in dealing with these difficult cases, which can no longer (as in the last war) be classified simply as "V.D.H." or "D.A.H."

Dr. Wood has enumerated the aetiological factors that have been described by various authors, but it may be doubted whether many of these writers had much "first-hand" knowledge of the soldier's life. No one doubts that personal and family histories are of great importance, but there were many other factors in the last war that conduced to the production of Da Costa's syndrome, and, apart from deliberate attempts to obtain discharge from the Service by eating toxic substances—for example, cordite, soap, or tobacco—there were many other causes. One potent factor was the endeavour to train recruits (too often entirely unaccustomed to physical exercises in civil life) in the minimum time. The instructors were usually hard-bitten old soldiers who showed their contempt for "conscripts" by shouting: "I'll make you or break you."

Another aetiological factor was excessive smoking, especially before breakfast. I have often seen recruits going down to

e ablution benches smoking at 5.30 a.m. (reveille was rlier in those days!). May I relate a personal experience at convinced me that tobacco might be a cause of Da Costa's ndrome? In 1935 I began to suffer from moderate dyspnoea exercise, occasional (L.) inframammary pain, and palpita-on. I consulted Dr. G. E. S. Ward. His first question fter an electrocardigram) was: "How many cigarettes do u smoke?" I replied: "I seldom smoke in the daytime, but ay smoke six or eight cigarettes when reading after dinner." r. Ward's comment was: "You take your poison in con-ntrated doses; you must cut it down." I replied: "If that the cause I will cut it out entirely." I did so, and all the squieting symptoms vanished quickly. I have smoked only ie cigarette since September, 1935; that was pressed upon e by a friend at a mess dinner four years later. I did not ijoy it and have not felt any desire to smoke again. In ctober, 1939, I was passed "fit for general service." The edical officer who examined me said that my blood pressure as only 135/90. While I smoked my systolic blood pressure id been 142 to 146 for more than twenty years.

We know that Vaquez and other eminent French cardiolo-sts considered that tobacco, alcohol, and black coffee were ie three most potent causes of cardiovascular disturbances ifty years ago no men in training for athletic sports were ermitted to smoke. Is it not probable that the modern laxation of that rule has not improved the health of the sing generation?—I am, etc.,

Nether Stowey, June 13. C. W. J. BRASHER.

SIR,—I was much interested in Dr. Paul Wood's lectures May 24 and 31 and June 7), and I wish to compliment him n his magnificent work. Personally it afforded me peculiar ratification inasmuch as I had, to a certain extent, arrived at imilar conclusions in another sphere of research. Like him, hope that the diagnosis "effort syndrome" will be dropped, ut, like many others, I also hope that no more syndromes or liseases will receive a person's name, and for the want of a etter term I suggested "emotional D.A.H." in a preliminary eport published in the *Practitioner* in September, 1940.

In all the cases I have investigated, a *central taint*, the result f fear, could be discovered, but I am not unmindful of the act that strain may be an aggravating factor. Furthermore, t is my opinion that D.A.H. is relatively a lesser concern in his war because the Army is now largely mechanized, and in hat way the soldier's heart is not subjected to the strain of he old foot-slogging days.

I have found children's hearts a fertile field for research, nd during the last year I have been investigating such hearts nder the auspices of the L.C.C. and the Finchley Borough Council. This work was unfortunately interrupted by enemy ction and has been further delayed by my inability to get permission from the local authority to examine children's hearts in this area, despite the offer of full co-operation from the War Office and hospitality at the county hospital.—I am, etc.,

Solva, Pembrokeshire, June 11. J. STEPHEN LEWIS.

Treatment of Mustard-gas Lesions of the Eye

SIR,—An instruction (E.M.S. I.252 (revised)) on this subject has been widely distributed to the officers, consultants, and hospitals of the Emergency Medical Service. It came before the Medical Board of Moorfields Eye Hospital "for your information" The Medical Board considered the instruction and felt that several points in it required comment.

1. The use of albucid solution is advised at first-aid posts and at hospitals in cases in which the eyes have been affected by gas vapour or gas splashing. It must be pointed out that the use of sulphanilamide preparations is not directed against gas contamination but only against subsequent infection of the conjunctiva, and that opinion as to its efficiency in this latter respect is far from being generally favourable.

2. No mention is made in the instruction of the very diverse lesions which may be produced by gas, most of them slight and very few of them serious.

3. No indication is given of the treatment necessary when the cornea is definitely involved, and while water is advised for irrigation of the eye at an incident and at first-aid posts, no advice is given as to the lotion to be used for the irrigations recommended at hospitals.

It would appear that this instruction is not in fact the "result of further experience" and should be withdrawn and replaced by a carefully considered and detailed note based on actual experience obtained in the last war and on substantiated experimental evidence.—We are, etc.,

Royal London Ophthalmic Hospital, June 16. F. A. JULER. MAURICE WHITING.

Differential Diagnosis of Contusion of the Brain and Psychoneurosis

SIR,—Dr. W. A. Brend, in an article in the *Journal* of June 14 (p. 885) on the differential diagnosis of contusion of the brain and psychoneurosis, under the subheading "The Clinical Pictures" makes the following statements: "The outstanding feature in contusion is the headache. . . . The sufferers complain of it at once. . . . They describe the pain . . . as being like that cause by a *tight band round* the head. In neurosis, on the other hand, headache is not a typical symptom . . . it is often mentioned only at the end of the story almost as an afterthought." The clinical fact is that headache is a typical symptom in neurosis. In actual practice the neurotic patient in the consulting-room or out-patient department nearly always complains of it, gives it a prominent place in his list of sufferings, and often describes the feeling he experiences as "*being like that caused by* a tight band round the head"

In the next paragraph Dr. Brend writes: "Inability to concentrate is the other cardinal symptom in contusion. . . . A characteristic feature is the forgetting to carry out small intentions. The sufferers go out intending to do something, but return without having done it. . . . The neurotic may complain of inability to concentrate . . . but when pressed to give specific instances he is often at a loss to find any. . . . The contused person is often abstracted; the neurotic is usually too self-centred to leave his luggage in a train." Again, in practice, the clinical fact is that inability to concentrate is a cardinal symptom of neurosis. The neurotic constantly emphasizes the discomfort he experiences as a result of his failure to perform the ordinary routine of the day satisfactorily; and a characteristic feature of this is "the forgetting to carry out *small intentions*."

Finally, one of the commonest complaints made by the neurotic is that he "feels such a fool" because he is continually leaving his belongings in a train, a bus, a tramcar, or a taxi.—I am, etc.,

London, W.1, June 14 MURDO MACKENZIE.

Orthopaedics

SIR,—The letter from orthopaedic surgeons (May 24, p. 791) contained an unfortunately incomplete statement, which, taken out of its context, can be made to look ridiculous. Some later commentators, with an evident bias against orthopaedics, have shut their eyes to the *obvious meaning—namely*, that such physical medicine as is used in orthopaedics is a part of orthopaedics. Most people are extraordinarily ignorant of the scope and methods of orthopaedics, and this is suggested even by Lord Horder's recent report on rheumatism.

It is unfortunate that we are called orthopaedic *surgeons*. Because of this many people think of us only as manipulative or operative technicians. Whatever other people would like us to be, *the fact remains that our work is not so restricted*. Orthopaedics is concerned with the diagnosis, prevention, and treatment of the deformities and disturbances of function of the locomotor system. (I realize that it is easy to pick holes in this: an intracranial endothelioma or a Bartholin's abscess may both interfere with locomotion, but there is complete understanding between neurosurgeons, gynaecologists, and "orthopaedists" in these matters.) The work is done within organizations and in institutions specially designed, equipped, and staffed for the purpose, giving continuity of treatment under unified control from the onset of the injury or disease until maximum restoration has been achieved. At least two-thirds of an "orthopaedist's" time is spent on diagnostic and preventive measures, in which plans must be prepared and decisions taken, determining a period of treatment lasting from a few weeks to many months. We utilize with thankfulness the help of our colleagues in every field of medicine, but in our own particular schemes we are called upon to direct

the whole clinical organization. Equally we co-operate with our medical and surgical colleagues in other fields and leave them to run their shows as they like; often regretting that they do not take more personal interest in the physical therapeutic measures they employ.

The history of the last thirty years of orthopaedics will reveal an intense open-mindedness and keen investigative spirit which has surely contributed very largely to the advancement of medical and surgical practice in modern times. Orthopaedic principles, however, are at least as old as Hippocrates and are not, or should not be, peculiar to orthopaedics.—I am, etc.,

Exeter, June 16. NORMAN CAPENER.

Physiotherapy

SIR,—I have read with such interest the recent correspondence in your *Journal* on the above subject that I am emboldened to crave yet a little more space to sum up the various points which have been brought forward. I feel that I am perhaps privileged to do this, first on account of my advanced age—a fact that I am never allowed to forget by the Army—and, secondly, that I have had the great good fortune to practise this art in types of hospitals and clinics which it has not fallen to the lot of many of the writers to do.

Physiotherapy seems to convey " so little to some " and so " muddled an idea to others " that the attempt to elucidate its aims and objects as set out in letters both in the lay and medical press needs no excuse. In fact were the truth known one could almost apply the words of our beloved Prime Minister: " Never have so many owed so much to so few," to this branch of medicine.

A few pioneers have not only attempted but have succeeded in placing this science on a reputable basis if not on a secure foundation. That the foundation is insecure is not the fault of the pioneers themselves but due to the fact that the peoples of the countries which they have invaded (if such a term is applicable) have been slow to appreciate the benefits of methods with which until recently they have been unacquainted though the majority make use of them. *Timeo Danaos et dona ferentes.*

Physiotherapy belongs to every branch of surgery and medicine, and cannot therefore be relegated to any particular specialty. An adequate knowledge of all its applications requires years of study not only of physics, electrical phenomena, and dynamics, but also of all the organs and tissues of the body, and can therefore be approached only from a very wide perspective. The adviser in physical medicine must above all things be a general practitioner in its widest sense. To approach this subject without a comprehensive knowledge of disease in all its forms is doomed to failure. If assistance is to be given to the surgeon or physician in all the various specialties then surely the adviser in physical medicine must have a wider outlook than that conveyed by the term " orthopaedic physician." To subdivide the subject of physical medicine into watertight compartments to suit every specialty would be a waste of human energy both male and female.

I have the honour of serving a certain hospital in the Emergency Medical Service where has been instituted a regular monthly consultation between all the orthopaedic and neurological surgeons and the physiotherapy specialist, which seems to work smoothly and to be of infinite value at any rate to the latter. In the end it saves time, and instead of the passage of notes between one department and another ideas are exchanged in a friendly atmosphere and the patient undoubtedly benefits. Why should not this atmosphere exist in every hospital or institution? To my mind, the answer is that there lingers in the minds of the surgical and medical staff of most of our hospitals an element of doubt as to the efficacy of physical treatment and the integrity of the physiotherapy specialist. If this is the case then surely there is a remedy.

No confidence will ever be established in the medical mind—though it has long been established in the lay mind—until one of our great universities takes up the investigation of this subject and either substantiates or disproves its claims. What better opportunity could exist than the present crisis, when unfortunately plenty of material for research abounds? I would go further and suggest that the university of choice would be Oxford University, which, through the munificence of Lord Nuffield, has ample funds at its disposal for research of all kinds. Are we to leave this work once again to our allies the Americans or our present foes the Germans? Can not Britain for once be first in the field and demonstrate to the rest of the world that even in the midst of war her energies can be directed towards reconstruction in a tangible and humane manner?—I am, etc.,

Northwood, June 19. L. D. BAILEY.

The Field of Physiotherapy

SIR,—The executive committee of the Society of Physiotherapists have read with interest the annotation on " Physical Medicine, Orthopaedics, and the Services," published in your issue of April 26, and the correspondence which has followed it.

The British Medical Association was mainly responsible for the establishment of the National Register of Medical Auxiliaries, which pledges the physiotherapist registered therein to work under medical direction. We are therefore surprised to note in the letter from the British Orthopaedic Association published in your issue of May 24 that " the British Medical Association, in one of its most successful reports, deplored the system by which surgeons treated their cases to a certain point and then handed them on to masseuses and physiotherapists, so that the surgeons knew nothing of the end and the physiotherapists knew nothing of the beginning." From this statement it would appear that the British Medical Association were discouraging the employment of a body of trained medical auxiliaries whose registration they had promoted and sponsored.

The confusion which still exists in the field of physical medicine is to be much regretted, and the registered physiotherapist has suffered much on account of this. He has been specially trained for this field and his qualifications limit him thereto and to work under medical direction. Physical medicine needs its trained administrators as much as any branch of therapeutics, yet through lack of appreciation of this point many members of the medical profession employ the non-registered worker in this field. We have many examples of this, and have been in communication with the British Medical Association recently on the subject. In this connexion Sir Morton Smart's remarks in your issue of May 24 on the dilution of labour in our field are most timely, and his warning should not be disregarded.

It has been obvious for some time that some authoritative control of physical medicine is essential: whether this is Governmental or independent is not of great import; but it is essential that the right members of the medical profession who know its history, its scope, and its services should be in control of it. May we hope that the correspondence published in your columns will stimulate interested members of the medical profession to take counsel together and endeavour to bring order out of the present chaos.—I am, etc.,

W. D. A. BURNELL,
Chairman, Executive Committee, Society of
London, S.W.1, June 14. Physiotherapists.

Hospital Administration

SIR,—Some play is made in the current issue of a periodical called the *Hospital*, the official organ of the British Hospitals Association and of the Incorporated Association of Hospital Officers, with the advocacy of lay as opposed to medical internal administration of hospitals. This advocacy is quoted as coming most recently from three doctors, in a literary effort entitled " Post-war Hospital Services " and published in the *Lancet*. Reference is also made back to the utterances of a fourth doctor who is styled the *Lancet* Special Commissioner and who expressed similar views. I make no comment upon the fact that the *Lancet* has twice provided grist for this propaganda mill directed against a section of the profession for which it is published. An attempt is also made to rope in the leading article in the *British Medical Journal* on medical man-power, but it misses fire badly because the remarks quoted had no reference to medical superintendents. I would expect the *Journal* to be conducted with too great a sense of dignity and justice to lend itself to an attack upon a medical section which these glib critics describe as " harassed officers, overburdened with work."

So far as I know, no medical superintendent or medical journal has, so far, made an attack upon the type of official variously described as secretary, secretary superintendent, house governor, or administrator, with or without some letters appended. I do not intend to do so and I hope none of my

colleagues will so demean themselves. Lay hospital officers are, like medical superintendents, busy people with a war on their hands. I will, however, make a few general observations addressed in particular to the type of medical critic which has been quoted.

They are, all four of them, much of an age and class so far as can be gathered from the information supplied by them to the *Medical Directory*. I would remind them that they write at a time when a large proportion of their age group is away serving with His Majesty's Forces, and that we will, by their leave, postpone these heavy decisions until those gentlemen who survive are with us again and in a position to add the weight of their views and experience. What serious-minded and experienced full-time hospital workers, medical and lay, are seeking is not a piper revolution in the absence of so many colleagues, but a sane evolution when they return. In the meantime, responsible persons will have no difficulty in putting statements such as that "the post of medical superintendent should be abolished" at their proper valuation. I would say the same, at the present time, of a similar statement regarding lay administrators.

In the final reckoning this question of medical superintendent or lay administrator will not be settled by the authors of "Post-war Hospital Services," or by the *Lancet* Special Commissioner, or by the British Hospitals Association, or by the Incorporated Association of Hospital Officers. It will not, in fact, be settled by any assiduous section grinding a busy axe. It will be settled by the common people, whose servants the hospitals are—by the force of public opinion expressed by their representatives on controlling bodies in the light of their own knowledge gained by experience.

At the present time all mental hospitals, municipal hospitals up and down the country on an increasing scale, many special hospitals, and even some "voluntary" hospitals, are administered by medical superintendents. Other "voluntary" hospitals have, to meet the needs of the Emergency Medical Service, so designated a member of their medical staff. That is a weighty fact. Medical superintendents can, and will, await the decision for their extension or abolition with equanimity. Time, the stress of war, and the knowledge which comes with experience will all work towards a correct and wise decision. I have friends among lay administrators and have too much regard for their worries and difficulties at this juncture to make an attack upon them as a class. Let us get on with the war and leave these spates of frothy wisdom until the piping times of peace, when our colleagues will be with us to help in building something worth while from the wreckage.—I am, etc.,

Reading, June 10. D. CYRIL THOMAS.

Chronic Sick in Bombed Towns

SIR,—The urgent and important problem in the hospital administration of this country raised by Sir Frederick Menzies concerns every large municipality, and is one which up to the present has not been solved. At this stage the Ministry of Health could with advantage include it in its new sphere of action in dealing with hospital accommodation generally. The Ministry before the outbreak of war did not intrude itself too obviously except in an advisory capacity in the administration of our hospitals. It has now launched the Emergency Hospital System and controls a large number of emergency hospitals all over the country.

The chronic sick question, with which Sir Frederick is fully conversant in his capacity as late Medical Officer of Health to the L.C.C., has reached the stage when only the Ministry of Health can and should deal with it. Estimates of the number of air-raid casualties anticipated at the outbreak of war have up to the present, fortunately, proved to be wrong. It is still possible that a larger number of beds may be required than have yet been called upon. These thousands of beds occupied by the chronic sick in our large industrial areas would be invaluable under such conditions.

The humanitarian aspect so rightly stressed by Sir Frederick is one which should appeal to all. It is astonishing that the leaders in our churches, our religious societies, or some strong voice from this wilderness of chaos, have not cried out on behalf of these poor and tormented souls. I have seen no record of any concern or effort by our colleagues in the House of Commons. This is surely a subject which should come within their purview. At the present time humanitarian grounds alone are sufficient reason, and indeed the principal one, for urgent steps to be taken for the transfer of these sick persons to quiet rural areas.

Large numbers of country houses have been taken over by the British Red Cross and other charitable societies. They have been fully equipped, and most of them staffed by local V.A.D.s, to take in patients. They are still empty and the V.A.D.s are bored and disheartened with no work to do. I have found that nursing staff who can nurse these chronic sick efficiently are competent to nurse any case. They are excellent material for the training of nurses in their profession, and our V.A.D.s would be all the better for this opportunity of relieving trained nursing staff of this arduous and important national duty.

I would not stress the economics of keeping chronic sick in urban areas at the present. This is a question which should have been settled in the pre-war period. It is so full of difficulties that all discussions seem to have led to no settlement. It is like playing with nettles. The old adage "Grasp a nettle and it will not sting" seems to be an appropriate one to this subject. The cost per patient in our large hospitals and institutions in urban areas varies from £3 to £6 a week. This in itself is a problem calling for serious thought. Whereas the healthy wage-earner is expected to pay his rent and rates and bring up his family on an average of £3 a week, the expense of maintaining the chronic sick is one which economists might well delve into. My view is that, economically, the present way of dealing with chronic sick is impossible, and will sooner or later have to be handled drastically. There are many interpretations of the term "chronic sick," and indeed each case has to be considered individually. Many of the patients are senile, others suffer from permanent or chronic disabilities. However, this is not the occasion to discuss this aspect.

The need now is for "evacuation" (not to other industrial areas), making use of all available accommodation in quiet rural areas where the majority of these persons can end their days away from the noise of gunfire and bombs and the fear of impending disaster. Above all let them not be evacuated to institutions where the stigma of "workhouse" still prevails. The "workhouse" dies hard, and this indignity would merely add to their mental anguish and troubles. Our care of the chronic sick in the past has been an example to all civilized countries. Let us not fail in our duties in these critical days.—I am, etc.,

June 12 "DE SENECTUTE."

Treatment of Injuries of the Fingers

SIR,—May I express my complete agreement with Mr. J. B. Oldham's letter (June 14, p. 906) and in particular with the functional and cosmetic advantages of amputation through the metacarpal shaft where this is indicated. There is, however, one further point which should be stressed—namely, that the greater the injury to the hand as a whole the greater the relative advantages of conservative treatment become. One crippled finger in an otherwise perfect hand is a "lame duck" which hinders the rest. The same finger in a damaged hand may contribute its full share to the use of that hand.

A case of mine may illustrate this. Six years ago a shoe operative had the misfortune to have his left hand caught in a press. The flexor sublimis tendons to all four fingers were severed, and the flexor profundus tendons to the middle and little fingers as well, across the proximal phalanges. I sutured each with a single stitch of fine catgut and excised and repaired the wounds. The hand, wrist, and elbow were kept in flexion. He had no later treatment except the movements that he could do himself; in these he was intelligent and persevering. I saw him a few days ago, and, having this correspondence in mind, asked him if he thought I had been in error in failing to amputate his fingers. His reply was appropriate, but cannot be given verbatim. I gather that he is quite satisfied with things as they are. He can flex his hand as a whole, and the index and ring fingers separately. With it he can do a full day's work at his old job, and has done so ever since his recovery from the injury. He also cultivates his garden and an allotment in his spare time. Admittedly he does not have to do fine and accurate work with the damaged hand, but he can do all that he wants to do, and much more than he could have done without his fingers.—I am, etc.,

Glastonbury, June 16. R. M. AINSWORTH.

Subcutaneous Ligature of Veins

SIR,—Dr. H. S. Russell's reply (June 7, p. 870) to the critics of his operation for varicose veins of blind ligature somewhere in the thigh, followed by injections of sodium morrhuate, constrains me to add my deprecation of this dangerous and inefficient procedure. I do so because sodium morrhuate is of variable chemical composition, and enough sudden deaths and anaphylactic collapses have been reported following its use to warrant its final abandonment for the injection of varicose veins, especially as there are many other safer and more effective substances (quinine and urethane, sodium salicylate 30%, quinine and urethane followed by lithocaine). Sodium *morrhuate at best is a poor sclerosing agent.*

I have been interested in the operation of simultaneous ligature and injection of gross varicose veins since 1932, and have performed the operation between two and three hundred times A follow-up has shown that if any ligature is placed lower than the actual union of the internal saphenous vein with the femoral vein it will be followed by recurrence in a high percentage in a period of three months to three years. J. B Oldham's experience corresponded with this. I entirely agree with Mr. N. L. Eckhoff's letter (May 10, p. 729), pointing out the weakness of Dr. Russell's method. I would condemn it as being dangerous to patients, of doubtful service to their need, and likely to bring disrepute to the good name of surgery for varicose veins.—I am, etc.,

London, W.1, June 10 HAROLD DODD.

"Egyptian Tummy"

SIR,—"Gippy tummy" differs clinically in no way from the so-called "Madeira fever" or "Riviera gripes." Colic, diarrhoea, often fever and vomiting present a picture of severe enterocolitis or gastrocolitis. Heat, flies, and filth seem to be the prerequisites of the attack, which is represented in this country by its summer diarrhoeas and food poisonings.

Both in Egypt and Madeira one's chances of dodging the complaint are increased by avoiding uncooked food (except peeled fruit), milk, and water from the tap. I share Sir James Barrett's view (June 14, p. 906) that this is an infective disease which may be influenced, but certainly not caused, by climatic changes. That causative organisms have not been isolated is partly due to lack of enthusiasm to find harmful microbes in expensive winter health resorts (the visitor is always assured that he has been eating too much fruit); partly to lack of facilities for investigation of fresh stool passed early in the attack; and partly to the inherent difficulties of isolating the organism which apply equally to food poisoning in England as elsewhere.—I am, etc.,

London, W.1, June 13. A. H. DOUTHWAITE.

Abdominal Pain after Opium

SIR,—I have read with great interest the account given by Col. H. L. Tidy (June 7, p. 870) of the experiments carried out at the Mayo Clinic to show the effects of morphine on the biliary ducts and the sphincter of Oddi. Some time ago in the *Journal* I drew attention to these experiments in an article on the exploration of the common bile duct for stone,[1] and, if I mistake not, the present discussion was initiated by Dr. J. B. Williamson in a letter with reference to this article—a letter in which he recorded the adverse effect of morphine on one of his patients who had undergone cholecystectomy.

It is to be noted that in the cases investigated at the Mayo Clinic the gall-bladder had been removed, and there is evidence to show that in such cases the sphincter of Oddi alters somewhat in function. Col. Tidy recalls that when a meal is taken the gall-bladder contracts, the sphincter of Oddi dilates, and bile runs into the duodenum. Doubilet and Colp[2] found that after cholecystectomy neither an ordinary meal nor a fatty meal had any influence on the sphincter of Oddi, the sphincter in one case remaining closed for not less than forty minutes after a fatty meal. Furthermore, it must be remembered that all these experiments were carried out on patients who had suffered from pathological conditions of the biliary tract and who were still probably suffering from spasm of the sphincter of Oddi. There is no evidence in the notes of the cases to show that dilatation of the sphincter had been carried out at operation—a step advocated by surgeons generally, including some of the surgeons at the Mayo Clinic.[3] In fact Walters and others[4] suggest the use of morphine as a diagnostic measure in cases with a post-cholecystectomy syndrome—an attack of pain following the administration of morphine being strongly suggestive of sphincter spasm or overlooked stone in the common duct. I have not known of any case of biliary colic following dilatation of the sphincter, and although I have not carried out any investigations to show the effect of morphine on the dilated sphincter, it happened that in one of my cases omnopon (52% morphine) was inadvertently given before cholangiography; this drug did not seem to interfere with the free entry of the opaque medium into the duodenum.

Whether morphine has any effect on the intact or healthy biliary apparatus is another question. Cases are known where repeated administration of morphine gives rise to clay-coloured stools, but not to biliary colic, and the conclusion to be drawn from the investigations already mentioned is that biliary colic following morphine is highly suggestive of a pathological condition of the biliary apparatus.

Biliary colic, however, will hardly explain the abdominal symptoms in every case in which the patient displays an idiosyncrasy to morphine. It would not seem to be the answer to the remarkable series of cases published by Mr. Winsbury White (March 22, p. 461), or the experiences recorded by Drs. Stephen Falla (May 17, p. 763) and Marcus Liddle (May 3, p. 688). From the clear account given by these observers severe spasm or colic of some other part of the gastro-intestinal tract would appear to be the cause of the untoward symptoms. Further experiments carried out at the Mayo Clinic support the views of Dr. Falla. McGowan and others[5] showed by *x*-ray that morphine produces spasm of the duodenum, and similar effects in the large intestine following morphine were observed by Jackman and Bargen.[6] The latter observers found that atropine was not very helpful as an antispasmodic; traesentin was much more effective; best of all was spasmalgin (papaverine compound).

Some doctors are still very reluctant to give morphine after abdominal operation for fear of causing ileus, but a great many surgeons believe that the increased tone and peristalsis produced in the small intestine by the drug prevents rather than gives rise to ileus. In fact it is the practice of some surgeons to combine morphine with prostigmin *before* abdominal operation in an effort to forestall this complication.—I am, etc.

Vitamin C from Rose-hips

SIR,—Dr. K. E. Barlow (May 24, p. 797) draws attention to the value of rose-hips as a source of vitamin C, with a reference to their use in Denmark. Dr. Barlow is right, as wild rose-hips are used all over the Continent for this purpose, and the Germans planted rose-hips along their new country roads, as well as using now the hips of the conquered Eastern European countries for this purpose.

The *Annales Paediatrici* (Basle), in May, 1939, published an article on this matter entitled "Der C-Vitamin-Gehalt verschiedener Hagebuttenspeisen," by Drs. Gedda and Kjellberg (Vol. 153, No. 2), on work done at the Children's Hospital in Gothenburg, under Prof. Arvid Wallgren. Work has also been done in Scotland by Miss Andross of the West of Scotland Domestic Science College on the preparation and popularization of wild-rose soups. During the past two years I have been collecting and translating Continental recipes and testing and adapting them for easy use in this country. The suggestion that wild rose-hip preparations should be used in welfare centres was put before the Maternity and Child Welfare Section of the Society of Medical Officers of Health in summer 1940, and welcomed as a possibility, if arrangements could be made for preparation and delivery to the centres. During last year negotiations were carried out between the Women's Institutes and several other organizations by members of the Food Education Society and myself, with regard to the organization of parties for picking and preparation of hips. Prof. Drummond, in replying to questions concerning the preparation of rose-hips, writes: "The Eastern hip is a much larger and juicier one than that obtained in this country. Nevertheless, we should do all we can by

local organization to make use of foodstuffs of the woods and hedgerows."

There are also difficulties in the making of hip preparations here which need to be overcome; notwithstanding this fact, all the hip preparations which I finally succeeded in making last year and the year before from local wild hips were attractive in appearance and of a delightful flavour. In one instance where hips were put before a children's party and put on the table without a word with other jams, it was the hip-jam pot which was emptied first.

I am enclosing a leaflet which was prepared last year and which gives the recipes that have been tested. I agree with Dr. Barlow that if official recognition could be obtained for wild rose-hips, a most valuable addition would be gained for the nation's sources of vitamin supply.—I am, etc.,

Hedgerose, Buckland Common, Tring, Herts, May 29. CLAIRE LOEWENFELD.

Sulphapyridine in Subacute Bacterial Endocarditis

SIR,—Dr. J. G. Macleod (June 21, p. 927) contrasts the results in cases treated with sulphapyridine and heparin with those in cases treated with sulphapyridine without heparin. The former method of treatment has as yet justified no hope, but by the latter a few hopeful results have been obtained. These, however, should be contrasted with results without the use of either heparin or any sulphonamide—for instance, with that in a case which I recently described (*Lancet*, 1941, I, 630), in a portion of the cases referred to by J. A. Capps (*Ann. intern. Med.*, 1939, 13, 280), those of M. Haines (*Lancet*, 1941, I, 681), and those of E. Libman, in his pioneer observations of 1913 (*Amer. J. med. Sci.*, 146, 625). In spite of this last class, though remarkable remissions have occasionally been observed—I have heard of one case in which there may actually have been recovery, as the patient was lost sight of after remarkable improvement—I am nevertheless in favour of trying sulphapyridine, because without treatment, if a stage is reached in which all signs of active infection disappear and remain absent, the damage already done (notably results of cerebral embolism) is likely to be already so great that one is not justified in speaking of *recovery from the disease*, though one can suppose there has been recovery from the infection.—I am, etc.,

London, W.1, June 21. F. PARKES WEBER.

Medical Planning Commission

SIR,—At the first meeting of the Medical Planning Commission Lord Dawson of Penn is reported (May 17, p. 759) to have said: "The practice of medicine in all its branches must become increasingly institutional." What, I ask myself, are the full implications of this statement? Does it imply that more and more patients will be treated in hospital, or does Lord Dawson include his primary centre, which the late Sir James MacKenzie considered, in my opinion quite wrongly, as almost the only commendable part of the scheme set forth in a notable Cavendish lecture?

Such institutional medicine as can be carried out in a fully equipped primary centre would inevitably tend to decrease the subsequent need for treatment inside a hospital. Shall we never seek to implement our oft-expressed opinion that the general practitioner is the backbone of the profession by giving him as easy access to the means of early diagnosis and treatment as has the consultant, general or specialist? Such possibility of early diagnosis and treatment should be available to every member of the community irrespective of the individual's means, and the Medical Planning Commission might well make such provision its first consideration. No medical scheme without it can be really satisfactory.—I am, etc.,

London, W.8, June 16. HAROLD H. SANGUINETTI.

R.M.B.F.: Loss in Income of £1,292

SIR,—The above heading sufficiently explains the reason for this letter. This loss in annual income is very largely due to the fact that many of our regular subscribers practising in towns heavily bombed have suffered serious financial loss and have had to reduce or cancel their subscriptions. Their number may well increase before the war is over.

Everybody knows the beneficent work of the Royal Medical Benevolent Fund in helping those members of our profession, their wives, widows, and children, who are living in straitened circumstances, and who, in many cases, are quite unable through age and infirmities to do anything to help themselves. The committee has done everything possible to cut down overhead charges. Administration is carried out with a reduced staff in less costly offices. Expensive annual reports have been abolished, and one way and another we have managed to effect a considerable saving in our annual expenditure.

Unfortunately, however, this is not nearly enough, and if the work is not to be seriously crippled we must get more help. We need donations to meet the present emergency, and especially we need many more annual subscriptions. Poverty is hard to bear under any circumstances, but when accustomed help is curtailed and prices are soaring—as is the case to-day—then the position may well become desperate.

Here is a passage from a letter which reached me the other day: "I am sending you a donation as a thank-offering for the fact that circumstances have placed my life in a spot where there is less danger from enemy action than is the case with my brother practitioners." I appeal to all your readers who feel that they are in similar fortunate circumstances to come forward at this critical time to help in carrying out our duty to our distressed colleagues. Contributions should be sent to the Royal Medical Benevolent Fund, 1, Balliol House, Manor Fields, Putney, London, S.W.15, and will be gratefully acknowledged.—I am, etc.,

ARNOLD LAWSON,
June 18. Chairman of the Committee of Management.

Obituary

JOHN RHODES DICKSON, O.B.E., M.B., C.M.

News has been received of the death of Dr. John Rhodes Dickson of Port of Spain, who has been a member of the British Medical Association for thirty-three years and was appointed honorary secretary of the Trinidad Branch in 1932.

Dr. Dickson was a medical student at the University of Edinburgh and graduated M.B., C.M. in 1889. He took the D.P.H. of the English Conjoint Board in 1899, the D.T.M. of Liverpool in 1905, and the B.Sc. (Public Health) of Edinburgh in 1909. After long service as deputy surgeon-general and medical inspector of health for Trinidad and Tobago he became medical and health officer to the Imperial College of Tropical Agriculture, Trinidad. He represented his Branch at the Annual Meetings of the B.M.A. at Dublin in 1933 and at Oxford in 1936.

At its last meeting the Trinidad Branch Council passed a resolution expressing sorrow at Dr. Dickson's death and condolence with his family, and the president, Dr. Eric de Verteuil, in moving the vote, paid tribute to his memory: "With the passing of Dr. Dickson," said Dr. de Verteuil, "we have lost an esteemed and respected colleague, a devoted and conscientious secretary, and above all a true, fast, and sincere friend. In this Council and among us here now, we may, I am sure, claim to have some of his most intimate, sincere, and genuine friends—friends who were able to value at their true worth his remarkable qualities of mind, character, and devotion to duty and to the public good, the richness of which appeared to grow brighter and to become more accentuated as the years rolled by. Dr. Dickson was fortunate in retaining to the end a full degree of his mental vigour, his gentle yet dignified bearing, and his cheerful and lovable nature. And we too in turn were blessed in sharing this good fortune."

Dr. GEORGE HENRY DUPONT, who retired in 1938 after having held the position of medical officer of health and school medical officer for Twickenham for twenty-eight years, died on June 11. He studied medicine at the University of Edinburgh, graduating M.B., C.M. with honours in 1893, and proceeding to the M.D. in 1898; four years later he took the D.P.H. of the English Colleges. In addition to his official posts in the Borough of Twickenham Dr. Dupont had been consulting physician to St. John's Hospital, Twickenham, and consultant to the Metropolitan and City Police Orphanage until its closure. He was a Fellow of the Society of Medical Officers of Health, a member of the Royal Sanitary Institute, and author of the Health Reports for Twickenham from 1910 to 1938, when he was made consulting M.O.H.

The Services

NAVAL AWARDS

Surgeon Commander John Joyce Keevil, R.N. (H.M.S. *Illustrious*) has been awarded the D.S.O. for great ccurage and devotion to duty in the face of enemy air attack.

Surgeon Captain J. Martin, R.N. (ret.) has been awarded a Greenwich Hospital Pension of £50 a year in the vacancy caused by the death of Fleet Surgeon J. H. Acheson, R.N. (ret.).

Temporary Surgeon Lieut. Thomas Tibbott Davies, R.N.V.R. (H.M.S. *Illustrious*) has been mentioned in dispatches.

AUXILIARY R.A.M.C. FUNDS

The annual meeting of the members of the Auxiliary R.A.M.C. Funds will be held at 12 noon on Friday, July 11, at 11, Chandos Street, Cavendish Square, W., when the annual report and financial statement for the year ended December 31, 1940, will be presented and the officers and committee for the current year elected.

CASUALTIES IN THE MEDICAL SERVICES

ROYAL ARMY MEDICAL CORPS

Missing

Captain Nicolas Shtetinin Seaford.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

The following candidates have been approved at the examination indicated:

FINAL M.B.—*Part I (Surgery, Midwifery, and Gynaecology)*: R. M. Archer, J. D. Atwell, R. C. Barclay, D. V. Bateman, K. F. C. Brown, L. J. H. Burton, H. Butler, W. H. Chase, R. E. W. B. Comerford, E. D. Cullen, P. M. Daniel, B. Dansie, F. M. P. Eckstein, E. J. S. Evans, C. L. Grandage, R. E. A. S. Hansen, D. V. Harris, A. Holmes-Smith, E. B. Jarrett, R. Jenkins, J. S. Johnstone, K. H. Lim, L. R. McLaren, H. L. McMullen, J. M. Mungavin, P. H. Nash, T. P. Pattinson, A. G. E. Pearse, G. E. Pinkerton, G. K. Riddoch, P. Sainsbury, J. L. S. Smith, A. G. Stansfeld, J. H. Tasker, H. D. Teare, D. E. Thompson, D. G. Vulliamy, A. Waymouth, H. G. Wolskel. *Women*: H. M. Comely, A. Davies, D. H. King, M. Redfern Davies.

UNIVERSITY OF GLASGOW

William John Brownlow Riddell, M.D., D.O.M.S., has been appointed to the Tennent Chair of Ophthalmology from October 1, in succession to Prof. A. J. Ballantyne, who retires under the age limit.

Medical Notes in Parliament

Mental Hospital Staffs

On June 17 Mr. SORENSEN asked the Minister of Health whether he was aware of the increasingly serious situation in mental hospitals through the withdrawal of male nurses to the Forces, and if he was considering the possibility of an extension of the Essential Works Order to cover the need of these hospitals. Miss HORSBRUGH replied that as regards withdrawal of male nurses for the Forces, no change had been made in the Schedule of Reserved Occupations. Male nurses over 30 were not called up, and those under 30 were called up only for service in their profession. Applications for deferment of individuals received full consideration by the Minister, and in suitable cases recommendations for deferment were made to the Ministry of Labour and National Service. The Essential Works Order did not affect military service, but the Minister had under consideration the question whether an order of similar effect should be made in respect of mental hospitals.

Committee on Medical Man-power

Sir Francis Fremantle was informed by Mr. ERNEST BROWN on June 19 that Mr. Brown, the Service Ministers, and Mr. Johnston had decided to set up a committee to investigate, in the light of the recommendations of the committee presided over by Sir Arthur Robinson, what further steps could usefully be taken to secure the utmost economy in the employment of medical personnel in His Majesty's Forces, the Emergency Hospitals Scheme, and the Civil Defence Services, and all other medical services, including general practice. This committee was to report from time to time what should be the allocation between these services of the available medical personnel. It would begin its work at once. Its members were: Mr. Geoffrey Shakespeare (Parliamentary Under-Secretary for the Dominions), chairman; Prof. R. M. F. Picken, M.B., D.P.H.; Sir Alfred Webb-Johnson, F.R.C.S.; J. Crighton Bramwell, M.D., F.R.C.P.; Prof. Sydney Smith, M.D., D.P.H.; J. A. Brown, M.D.; William Malcolm Knox, M.B., Ch.B.; and medical representatives of the Admiralty, the War Office, and the Air Ministry. In addition the following agreed to be closely associated with the work of the Committee: Sir Charles Wilson, M.D., P.R.C.P., Sir Hugh Lett, Bt., P.R.C.S., and H. S. Souttar, C.B.E., M.D., F.R.C.S. (chairman of the Central Medical War Committee).

Mr. RHYS DAVIES asked if the committee would inquire into the difficulties of panel practice in National Health Insurance. Mr. BROWN replied that the terms of reference were wide.

Medical Advisory Committees

Mr. GROVES asked on June 19 how many medical committees, advisory or executive, were referred to by Mr. Brown in the national emergency; how, when, and by whom they were appointed; and what were their constitutions. Mr. BROWN gave the following list: The Central Medical War Committee and Advisory Emergency Hospitals Medical Service Committee, the appointment and constitution of which had been set out in October and December, 1939, and February, 1941, respectively; Medical Advisory Committee on Rehabilitation, consisting of a number of specialists on this subject invited by the Minister in November, 1940, to advise the Director-General, Emergency Medical Services, from time to time on the rehabilitation of patients under the Emergency Hospitals Scheme; Standing Committee on Physiotherapy, consisting of medical practitioners with special experience of this treatment, selected in July, 1940, by the Minister's consultant advisers in collaboration with official representatives of the specialists concerned, to advise the Director-General, Emergency Medical Services, on the facilities required for this treatment in hospitals under the Emergency Hospitals Scheme; Lord Horder's Committee on conditions in air-raid shelters (with particular reference to health) appointed on September 14, 1940, jointly by the Minister of Health and the Minister of Home Security, and consisting of Lord Horder as chairman, a senior medical officer of the Ministry of Health, the chief engineer of the Ministry of Home Security, and two lay representatives of voluntary organizations.

Medicine Stamp Duties

Captain CROOKSHANK said on June 19 that before the announcement of the abolition of the Medicine Stamp Duties their yield in a full year was estimated to be £800,000. The yield of the Purchase Tax on prepared drugs and medicines might in a full year be of the order of £3,000,000. Sir KINGSLEY WOOD on the same date told Mr. Horabin that he would not consider the introduction of a Bill to legalize the administration of the Medicine Stamp Duties. The legal action brought by Messrs. Woolworth merely illustrated the difficulties to which the administration of these antiquated Acts continually gave rise. Captain CROOKSHANK said on June 18 that before the decision was announced to repeal the Medicine Stamp Duties, proposals were considered for a revised method of taxation suggested by the Proprietary Association of Patent Medicine Manufacturers.

Mr. WHITE suggested on June 19 that widespread advertising of patent medicines, often with an appeal to fear, led large numbers of people to treat their own ailments instead of using the medical services available under the National Health Insurance Acts. Mr. BROWN said he had no specific evidence than any large number of insured persons treated their own ailments instead of consulting their insurance doctors. This was among the matters considered before Sir Kingsley Wood announced the decision to repeal the Medicine Stamp Duties.

National Health Insurance.—On June 10, Mr. ERNEST BROWN told Captain Plugge that the possibility of securing economy by the substitution of a yearly health and pensions insurance contribution

card for the two half-yearly cards now in use had been carefully considered from time to time, and was discussed with the Consultative Council on National Health Insurance shortly after the outbreak of war. After weighing the arguments for and against the suggestion, the Council unanimously decided that they could not then recommend its adoption, but he would certainly see that the matter was considered afresh in the light of present circumstances. He pointed out, however, that a yearly card would cover the period of a contribution year, running from July to June, and that the change, if found practicable, could not take effect until July, 1942.

EPIDEMIOLOGICAL NOTES

Infectious Diseases for the Week

The majority of the principal infectious diseases have declined somewhat in England and Wales during the week, with the notable exceptions of dysentery and enteric fever. In Scotland also both diseases are abnormally prevalent, especially enteric fever. About this time last year dysentery was gaining a footing which it established for the three succeeding months of the year. Speed in tracing cases and carriers, strict control over the handling of foodstuffs and instruction in the observance of the elementary rules of hygiene are the golden rules in the prevention of dysentery as well as of enteric fever. Where the communal and individual risk is large, recourse must be had to active immunization.

Scarlet fever advanced very slightly in England and Wales and considerably in Scotland; in both cases it has exceeded the 1940 level. During the last three weeks cerebrospinal fever has declined slightly in England and Wales. Of the 254 cases notified only 28 were in respect of non-civilians.

Dysentery

Despite the increase in notifications, only fifteen administrative areas were affected compared with twenty in the previous week. Lancaster and Surrey remain the chief centres, but an outbreak has appeared in the West Riding of Yorkshire, where last week only one case (in Sheffield) was encountered. More than 3 cases were recorded in the following areas: Lancaster 38 (Blackburn 5, Liverpool 1, St. Helens 1, Blackburn R.D. 5, Warrington R.D. 4, Whiston R.D. 13); Surrey 19, all in Coulsdon and Purley U.D.; Yorks, West Riding, 17 (Bradford 7, Mexborough U.D. 1, Shipley U.D. 9); Chester 5, in Macclesfield M.B.; Hertford 4 (Watford M.B. 3, Hemel Hempstead R.D. 1); London 4 (Kensington 1, Wandsworth 3); Stafford 4, in Uttoxeter U.D.; Caernarvon 4 (Caernarvon M.B. 3, Gwyrfai R.D. 1). In Scotland more than one-half the cases occurred in the burghs of Aberdeen 14, and Dundee 10. Of the remaining ten areas affected, more than a single case was reported only in Aberdeen County 8, Glasgow 3, Renfrew County 3.

Enteric Fever

Enteric fever has increased in geographical distribution as well as in numbers since the preceding week. Twenty-five areas—an increase of five—were involved. Three adjacent counties supplied more than half the total for the whole country—namely, Warwick 23 (Birmingham 14, Coventry 4); Stafford 15 (Smethwick 6, Walsall 3, Wolverhampton and West Bromwich 1 each, Amblecote U.D. 2, Brierley Hill U.D. 2); Worcester 15 (Halesowen M.B. 2, Kidderminster M.B. 7, Stourbridge M.B. 1, Malvern U.D. 1, Bromsgrove R.D. 4). Other areas reporting more than 3 cases were: Lancaster 8, Middlesex 8, London 6, Nottingham 4. In Scotland over three-quarters of the cases notified, which were all of paratyphoid B fever, occurred in Dundee; the remainder were in the counties of Fife 3, Perth and Kinross 2, Sutherland 2, Ayr 1, Lanark 1, Moray and Nairn 1, Renfrew 1, and Glasgow 1.

Cerebrospinal Fever

Despite the recent decline in the incidence of cerebrospinal fever, it remains widespread in distribution. Although forty of the sixty-five administrative areas are involved, in only five were more than 10 cases notified during the week—namely, Lancaster 46, Yorks, West Riding 33, Glamorgan 21, London 16, Warwick 13. In Scotland the disease is less widely distributed, affecting twenty out of the fifty-eight counties and burghs. Only in Glasgow 22, Ayr County 8, and West Lothian County 4 were more than 3 cases notified.

No. 22

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended May 31.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1941 (a)	(b)	(c)	(d)	(e)	1940 Corresponding Week (a)	(b)	(c)	(d)	(e)

Medical News

The National Association of Maternity and Child Welfare Centres and the National Association of Probation Officers, London and Home Counties Branch, are holding a joint meeting on Monday next, June 30, at 2.30 p.m., in the Hall, at 117, Piccadilly, London, W.1, when Miss J. E. R. Kennedy, probation officer, Willesden Police Court, and Dr. Leslie Housden, chairman, Mothercraft Teaching Subcommittee, will speak on "The Bearing of Mothercraft Teaching on the Prevention of Juvenile Delinquency."

About a hundred doctors who saw service in hospitals, at aid posts, rest centres, and incidents during the raids on Clydeside met in Glasgow recently under the chairmanship of Sir A. S. M. Macgregor, medical officer of health for the city, to discuss and exchange experiences. Dr. James Dunlop, the chief A.R.P. medical officer, described the first-aid and ambulance services in action, and Dr. A. B. Walker, hospital officer, the reception and distribution of casualties, the calling out of reinforcements, and the emergency evacuation of hospitals. Prof. C. F. W. Illingworth discussed briefly the nature of the injuries, the treatment, the indications for morphine, and the work of a large hospital where the windows had been destroyed early in the raid. Other speakers were Prof. J. A. G. Burton, Mr. James Russell, Mr. G. H. Stevenson, Dr. Hunter (medical officer of health for Clydebank), and several doctors attached to first-aid posts. Among the points emphasized were the need for better protection for first-aid posts, and for shelters at posts to be heated and lighted artificially, and the value of senior medical students in the work of a casualty unit. Sir Alexander Macgregor said that the casualty scheme had worked well. Some re-allocation of doctors should be made to minimize the travelling distance to first-aid posts, and more doctors should be available to go to incidents. There had been many examples of great coolness and courage on the part of doctors and nurses.

The name of Dr. George Seymour Swan, surgeon, Birkenhead, has been brought to notice for brave conduct in civil defence.

The February issue of the *Journal of the Indian Medical Association* is a conference number devoted to the proceedings of the 17th All-Indian Medical Conference held at Vizagapatam from December 27 to 29, 1940.

Vitamin preparations containing added medicaments are subject to purchase tax unless the proportion of the medicament is so small that it has only a nutritional effect.

In the Soviet Union there are at present 117,000 doctors to about 200 million inhabitants.

Letters, Notes, and Answers

All communications in regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A HOUSE, TAVISTOCK SQUARE, W.C.1.

Authors desiring REPRINTS of their articles must communicate with the Secretary, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors over-seas should indicate on MSS if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager (hours 9 a.m. to 5 p.m.). Orders for copies of the *Journal* and subscriptions should be addressed to the Secretary.

TELEPHONE No.—B.M.A. and *B.M.J.*: EUSTON 2111.

TELEGRAPHIC ADDRESSES: EDITOR, *Astiology Westcent, London;* SECRETARY, *Medisecra Westcent, London.*

QUERIES AND ANSWERS

Urticaria

"H.S." (Carlisle) would be glad to have any suggestions for treating a stubborn case of urticaria in a woman of 24. She has been a sufferer for several years and all the usual remedies have been prescribed without any effect.

Post-herpetic Neuralgia

DR. N. S. FINZI writes: With reference to the two recent inquiries about the treatment of post-herpetic neuralgia, I beg to inform you that treatment with very small doses of *x* rays to the posterior ganglia which are affected is a specific. The only case I have known to fail was one where the doses used were much too large and which was not treated by myself. I have had personal experience of the benefits of this treatment. The condition is made worse for a few hours and then steadily improves. If necessary the treatment is repeated at intervals of four to seven days.

DR. BASIL KIERNANDER (Oxford) writes: With reference to "M.B., B.S.'s" query about the above (June 7, p. 876), it is always worth trying a course of low-intensity, local, short-wave therapy to the painful area daily for a few weeks, as about 50% of the patients definitely find relief from it, in my experience. There is no method of differentiating beforehand, so far as I know, between the cases which will and which will not respond to treatment.

Income Tax

Purchase and Sale of Practice on Accepting Service Appointment

"N.D." retired on pension from one of the Services in 1937 and bought a practice. In September, 1939, he sold the practice and accepted a Service appointment. Can he claim any relief?

* * "N.D." is entitled to pay tax for 1937-8 to 1939-40 on the amount of his actual income; but he is not entitled to deduct any loss he may have incurred in taking over and giving up the practice, as such is a loss of capital.

Apparatus Prohibited from Use

"Diatherm" owns some high-frequency apparatus which he is prohibited from using under the recent Order. What income tax allowance can he claim?

* * As regards depreciation, the income tax allowance is, strictly, applicable only to diminished value by reason of *wear and tear,* and unused apparatus does not qualify for the allowance. But we apprehend that a concession might be made in the special circumstances. As regards loss of income, if the total earnings fall by more than 20% as compared with the previous year, "Diatherm" can claim to be charged on the amount of the profits for the actual year. Apart from this special war-time provision, however, in the long run the loss of income will be allowed for in that "Diatherm" will presumably in the end pay tax only on the amount of his profits taking one year with another.

Liability on Service Pay

"Lieut." gives particulars of his pay and circumstances and asks how he stands as regards income tax.

* * The amount of tax payable by him for 1941-2 is apparently about £58. It is not unlikely that monthly deductions in excess of the current sums are being made pending calculation of the actual amount due for the year. (Presumably our correspondent has made his return for the year claiming the appropriate allowances.)

LETTERS, NOTES, ETC.

Bee-sting Anaphylaxis

"D.S.O., M.D." writes: I doubt if anyone who has suffered from the effects of a bee sting in an acute form has ever described his symptoms, so I thought my experiences would interest some of my fellow members. On June 12, 1941, about 8 p.m., I was stung by a bee on the left ear. In a few moments I felt tingling in the head, neck, back, and the palms of the hands, and then all over the body. My eyes became "gritty" and the conjunctival vessels dilated. My face became very swollen. Next a marked urticarial rash developed all over my body and extremities. My lips were swollen and white; the rest of my face of a dusky blue colour. My pulse became fast and full and occasionally irregular, my breathing somewhat difficult. There were beads of perspiration on my forehead. This condition lasted for about half an hour. I was thirsty and drank about 1½ pints of soda water. Gradually the condition passed off, and in about two hours had practically subsided. I slept well during the night, but next day felt somewhat "washed out," but was able to do my work. Adrenaline was got ready, but as the condition was passing off was not used. I ought to add that in previous years I have had many bee stings, having kept bees for years, but never had a condition of anaphylaxis before. I am 69 years of age, and years ago had serum injections for prophylactic purposes on several occasions—antityphoid, antitetanic, etc.; also serum for diphtheria.

MESSRS. E. and S. LIVINGSTONE inform us that the premises occupied by their binders have been destroyed by fire, with the whole of the contents, which included all work in progress and a large reserve of bound stock of their publications. They are doing everything in their power to replace the more important books and those in constant demand, but some of these will be out of print for some time to come, and medical men interested in their publications are meanwhile asked to make allowances.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY JUNE 28 1941

THE INSURANCE CAPITATION FEE

INSURANCE ACTS COMMITTEE OF THE B.M.A.

A meeting of the Insurance Acts Committee of the B.M.A., principally to discuss the matter of the insurance capitation fee, was held on June 12, under the chairmanship of Dr. E. A. GREGG. A number of resolutions from Panel Committees and B.M.A. Divisions urging that the claim for an increased fee be pursued were before the Committee.

A letter from the Ministry of Health dated May 31 stated that the Minister was not able wholly to agree with the figure of 5½d. as representing the cash value of the enhanced practice costs, but, in view of the introduction of legislation extending the insurance remuneration level from £250 to £420 per annum and the consequential increase of between 400,000 and 500,000 in the total number of insured persons entitled to medical benefit, he was prepared, as from the date of operation of the proposed legislation, if approved by Parliament, to agree to a consolidated increase of 6d. in the capitation rate, being an undetermined amount in respect of increased practice costs rounded off to take account of the new class of entrants into medical benefit. Several members of the Committee took exception to the fact that the Association had not been consulted by the Ministry as to the bringing in of the new class of insured persons, as was done when the level was raised from £150 to £250 during the last war.

The Chairman considered that a large proportion of practitioners would not seriously object to the inclusion of the new class provided that the remuneration resulting from such inclusion was comparable with that received in respect of the same class at the present time. The Minister seemed to recognize that a higher remuneration should be payable for the new class, and had suggested a moiety addition to the amount to which he was prepared to agree as representing the increase in practice expenses—the increase being spread out over the whole of the insured class—namely, the nineteen millions already insured and the half-million to be brought in. On this basis, if the 6d. offered by the Minister was regarded as 5½d. in respect of increased practice expenses, and ½d. in respect of the new entrants, the increase for the new class worked out at 1s. 8d. He thought the Committee should register a protest against the manner in which the new arrangement had been introduced, without sufficient opportunity being given to the Committee to consider the matter and, if thought necessary, to consult the profession.

A member pointed out that as it had been stated that the raising of the income limit from £250 to £420 was a recognition of the increased cost of living, doctors also should be entitled to some consideration in that respect, and this gave the Committee the opportunity to reopen the question of the capitation fee generally as relating to all insured persons. Other members supported this suggestion, and the opinion was strongly voiced that new classes should not have been brought into insurance without an opportunity being given to representatives of practitioners of raising the question of the adequacy of the capitation fee as related to this new class. It was also pointed out that in accepting the same capitation fee for this new class of persons as for those already insured, the profession—which when juveniles were brought in had pressed that the capitation fee should be the same for them as for adults—would be in a strong position to claim the same fee for dependants when these in due course were brought in.

The Committee eventually agreed to three resolutions. The first was that the Minister of Health should be informed of the Committee's dissatisfaction at his action in introducing legislation for raising the income limit for non-manual workers before the Committee had been consulted on the merits of the proposal. The second was that, as the Government had decided to legislate in order to bring into national health insurance a new group, the Committee desired to reopen the question of the adequacy of the existing basic capitation fee and to have it determined now, either as a prior issue or as part of the settlement of a general capitation fee for all insured persons, including the new group. By its third resolution the Committee decided to make no objection to the raising of the income limit for non-manual workers to £420, provided that the consolidated capitation fee in respect of both the existing and the newly added insured population was adequate. It was also agreed that a Conference of Panel Committees should be called so that practitioners could express their views on the subject, and that the Minister should be approached and informed that it was proposed to call such a conference.

Other Business

It was reported that the Ministry of Health had agreed to the Committee's claim for an increase in the ordinary portion of the Central Mileage Fund at the rate of £22,575 per annum as from July 1 next.

Representations had been made to the appropriate Government Departments in favour of medical practitioners being permitted to stock and issue war injury continuation certificates. It was found that in many cases the Assistance Board was willing to take a risk, in the interest of speedy payment, in the case of first certificates, and men were collecting such certificates from their doctors and being paid on them. After the first certificate, however, the question of title to benefit had to be ascertained before a man was given a blank certificate to take to his doctor, and there were serious difficulties in the way of allowing practitioners to stock and issue continuation certificates. The Assistance Board had agreed that if its attention was drawn to any delay in issuing medical certificates in any area to approved cases it would immediately take the matter up.

At the recent first meeting of the Medical Planning Commission the Insurance Acts Committee was asked to nominate four practitioners (one of whom should be engaged in colliery practice) for co-option to the Commission. The Committee made the following nominations: Dr. D .O. Twining (Salcombe, Devon), Dr. P. V. Anderson (Shildon, Co. Durham), Dr. I. G. Innes (Hull), and Dr. D. J. B. Wilson (High Wycombe).

The Committee agreed to advise practitioners engaged in national health insurance work to use the War Emergency Formulary now in course of preparation.

SOCIALIST MEDICAL ASSOCIATION

The following resolutions were passed at the annual general meeting of the Socialist Medical Association on May 25.

Employment of Refugee Doctors

That in view of the recent appeal for a thousand doctors from the United States and the decision to employ fourth and fifth year medical students as house officers, this meeting protests most strongly against the Government's failure to make use of the medical services of the anti-Fascist refugee doctors in this country. Since only about 100 of the 1,400 now in England are being allowed to use their medical skill and training, we demand that there should be an immediate speed-up of the machinery to effect the registration and employment of eligible alien doctors, and that those now employed on demolition and construction work in the Pioneer Corps be released for work in which their medical experience can be used.

Factory Medical Officers

That this meeting considers that the policy at present supported by the Ministry of Labour and National Service of

appointment of factory medical officers by factory managements would be improved upon, in the interests both of the workers and of the medical profession, by introducing a scheme whereby these officers would be employed by and responsible to a local or central authority and their duties co-ordinated with the work of the local medical officers of health.

EMPLOYMENT OF DOCTORS OF ENEMY NATIONALITY

The Minister of Health states (Circular 2405) that it was not intended that the phrase "total medical staff" in paragraph 2(c) of Circular 2312 (*Supplement*, March 22, p. 38) should be limited to resident medical staff. Visiting medical staff normally attached to the hospital may be included as well as the total resident medical staff employed in the hospital. In a hospital in which the medical staff includes at least two *resident* doctors of British nationality it will be permissible to employ one doctor of enemy nationality, even though the total medical staff may be less than five (in a hospital with fewer than 100 beds) or ten (in a hospital with 100 beds or over).

RATIONING OF CLOTHING AND SURGICAL GOWNS.

The Board of Trade has stated that under present arrangements coupons must be surrendered for the purchase of operating gowns and white surgery coats worn by surgeons, doctors, and dentists. These garments are not covered by the term "workmen's overalls." The Board adds that the question of making some concession is under consideration. In the meantime the number of coupons required for these garments has provisionally been fixed at six. In the case of similar garments required for use in hospitals, practitioners should be able to obtain them through the special arrangements which have been authorized to enable hospitals to get supplies of certain articles coupon-free. Hospitals will give the trader a certificate specifying the goods needed and stating that they are for use in a hospital.

Correspondence

Capital Value of Practices

SIR,—A State service may be near at hand or far off, but before any such service is contemplated the first demand that the B.M.A. should make is that the capital invested in a practice should be returned, not necessarily on what the income is to-day but the actual amount paid for the practice at any time. This money represents a man's capital and often his life savings or borrowed money. No person in a democratic country should have this—probably the only source of income for his wife on his decease or capital for starting off his children in careers—confiscated. In no other business or profession is a business valued at nothing. A good practice has always been worth about two years' purchase, and for security of income it is probably worth more when compared with the purchase value in other professions and business.

Some correspondents in the *Supplement* give as their reason for seizure of capital values the fact that better hours and conditions of work, holidays, locumtenents in illness, and a pension will more than compensate. The opposite view can now be expressed. Many practitioners make by hard work over £2,000 a year; the most we shall be likely to get under a State service will be £1,200 to £1,500. It must be logic that capital should be returned if one is forcibly to have one's income reduced and one's *freedom in work removed*. No pension can compensate these two.—I am, etc.,

E. H. WALKER, M.B., B.S.

Torrington, Devon, June 15.

Why Save Petrol?

SIR,—Why save petrol? At this stage of the war it is proposed to hold a parade and march past of A.R.P. services in this area, at which the Regional Commissioner will take the salute. Half the authorities concerned were opposed to the idea, which was proceeded with on the casting vote of the chairman—a county official. It is proposed to have rehearsals, which will involve sending eight or nine vehic from this district a matter of twenty miles on seven occasio and the seven other authorities will have to do likewise. Th will be the cars of hordes of officials from the county authorit those of the heads of the local authorities and their clerks be presented, and the commissioner's car will have to bri him from his Olympian abode, and we shall march past h in completely bogus array in uniforms borrowed for t occasion, as we have not yet been equipped with our own.

All this would be mildly amusing were it not for the fa that, all told, over 500 gallons of petrol are going to be wast on a project whose value towards the war effort is exactly n I must confess that when I think of the difficulty I have getting a bare minimum of petrol to carry on my practice a that here is enough petrol to last me for nearly a year bei thrown away on a completely fatuous performance such as th rage and disgust are my uppermost feelings and not amus ment.—I am, etc.,

Stokesley, Yorks, June 14. H. M. MACGILL.

Postgraduate News

The Fellowship of Medicine announces the following courses for Fi F.R.C.S. candidates: (1) Revision course at Royal Cancer Hospital, dai 10 a.m. to 1 p.m., July 7 to August 1; (2) Practical operative surg course at Royal Cancer Hospital, Mondays, Thursdays and Fridays, 2 p.m July 7 to August 1; (3) Week-end course of clinical demonstratio Saturday afternoon and Sunday morning, July 12 and 13, at King Geo Hospital, Ilford; (4) Urology course at Colindale Hospital, Thursda 2.30 p.m., August 7 to 28.

A series of lectures on "War Surgery of the Chest" will be given at t British Postgraduate Medical School from Monday to Friday, July 7 to (both dates inclusive), beginning at 10 a.m. daily. The fee for the cou is £1 1s. Officers of the armed forces wishing to attend without payme should apply through their respective Director-Generals. Applications tickets should be addressed to the Dean of the British Postgraduate Medi School, Ducane Road, W. Further war surgery courses will be held follows: Beginning Monday, July 21, "War Surgery of the Nervous System August 11 to 22, "Operative Surgery in Wartime"; Beginning Monda September 1, "War Surgery of the Extremities."

WEEKLY POSTGRADUATE DIARY

FELLOWSHIP OF MEDICINE AND POSTGRADUATE MEDICAL ASSOCIATIO 1, Wimpole Street, W.—*St. Mary (Islington) Hospital*, Highgate Hill, N Wed., 2 p.m., Final F.R.C.S. Clinical Course.

DIARY OF SOCIETIES AND LECTURES

ROYAL SOCIETY OF MEDICINE

Annual Meeting of the Society.—Tues., 5 p.m. To elect Officers and Counci

DAVYHULME MILITARY HOSPITAL MEDICAL SOCIETY.—Thurs., 3 p.m Mr. Graham-Bryce: Injuries of the Chest. Medical men and women any of the Services, including civilian, will be welcomed.

VACANCIES

EXAMINING FACTORY SURGEONS.—The following [illegible] announced: Golspie (Sutherlandshire); Coventr[illegible] Applications to the Chief Inspector of Factories, [illegible], S.W.1, July 1.

APPOINTMENTS

DUTHIE, E. W., M.B., Ch.B., Examining Factory Surgeon for the Crude District (Aberdeenshire).

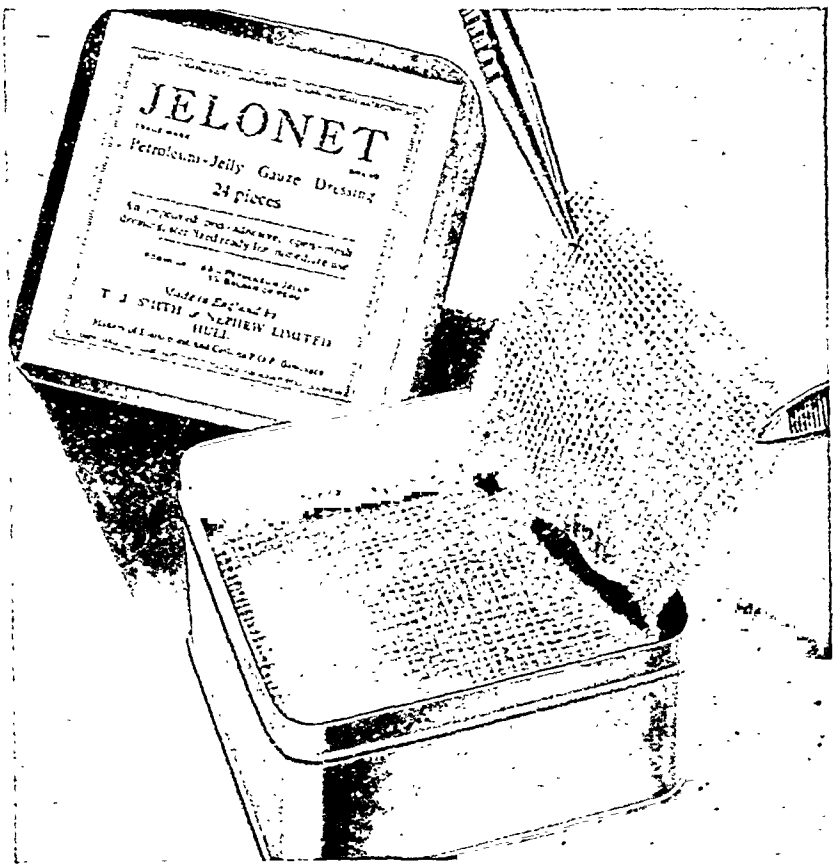
KITCHIN, KATHLEEN, M.B., B.S., Advisory Medical Psychologist, Wiltshi County Council.

SPROTT, NORMAN A., D.M., M.Ch., F.R.C.S., Medical Superintenden St. Columba's Hospital, Swiss Cottage, N.W.

BIRTHS, MARRIAGES, AND DEATHS

The charge for inserting announcements under this head is 10s. 6d. This amount should b forwarded with the notice, authenticated with the name and address of the sender, and shoul reach the Advertisement Manager not later than the first post Tuesday morning to ensur insertion in the current issue.

MARRIAGES



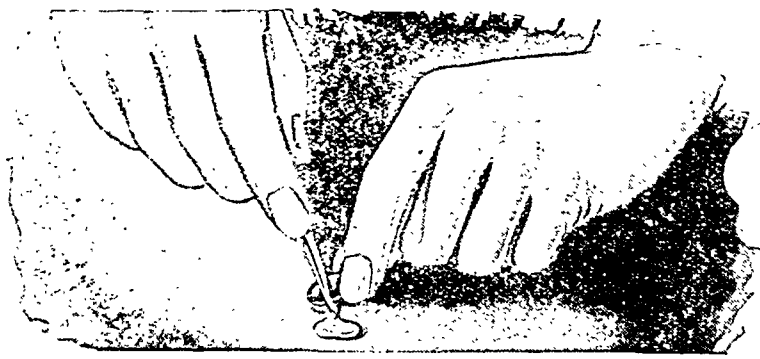
O'DONNELL—DILLON.—On April 14, at Church of Christ the King, Salthill Galway, Michael O'Donnell, M.D., M.R.C.P.I., to Moya Dillon, M.B.

STRATON—ADAMS CLARK.—On June 13, 1941, at Exmouth, very quietly Capt. Charles Noy Straton, R.A., son of the late Lieut.-Col. C. H. Straton R.A.M.C., and Mrs. Straton, of 2, Trinfield Avenue, Exmouth, to Evangelin Adams Clark, M.D., B.S., daughter of the late William Adams Clark M.D., and Mrs. Adams Clark, of Penge.

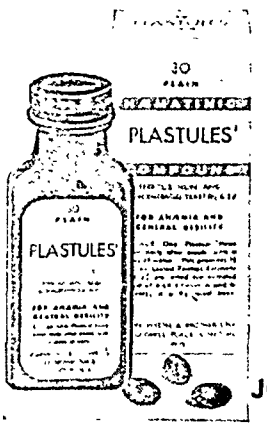
DEATH

HARVEY.—On June 17, 1941, at 4, Winn Road, Southampton, aged 67.

Local and E.M.S. hospital authorities are asked in a Ministry of Health circular to draw the attention of medical staff and others to the urgent need for conserving petrol. A reduction has had to be made in supplies, and everything possible should be done to see that the use of motor vehicles is restricted to the minimum necessary for the effective working of the hospital.



'JELONET' (TULLE GRAS) PETROLEUM-JELLY GAUZE DRESSING is made from a specially woven open-mesh gauze, evenly saturated with petroleum jelly and Balsam of Peru, and is packed in sealed containers of 24 dressings sterilised ready for immediate use.



'Jelonet' is indicated for Skin-Grafts, Compound Fractures, Burns etc., as a non-adherent dressing to promote granulation. The open-mesh dressing encourages free escape of discharge, and ensures ventilation for skin-grafts and young epithelium, with minimum trauma to granulations.

Uniform saturation with petroleum jelly prevents serious rise of temperature due to toxic absorption, secondary dermatitis of the surrounding skin arising from irritating discharge, and also permits ready extrusion from deep wounds.

Obtainable through your usual Surgical Supplier, 5/2d. per tin of 24 dressings. Special prices available to Hospitals. Made by the makers of 'Elasticplast' and 'Cellona.'

T. J. SMITH & NEPHEW LTD., HULL

The iron in 'Plastules' is ferrous iron—easy to take, easy to assimilate. In the soluble ferrous state, this iron is readily available for conversion into hæmoglobin. 'Plastules' hasten the restoration of normal hæmoglobin levels without the untoward effects of massive iron feedings. Suggested dosage—three 'Plastules' Plain or four 'Plastules' with Liver Extract daily.

'PLASTULES'
BRAND HÆMATINIC COMPOUND REGD.

thing more than the mere fitful consultation of voluntary hospitals by municipalities imposed by Sec. 182 of the Public Health Act, 1936, was required, and attention was drawn to the advocacy of this policy expressed by the Minister of Health (then Mr. Neville Chamberlain) immediately after the passage of the Local Government Act, 1929. The response to this appeal by local authorities was reluctant and variable. In some areas, such as Manchester and Oxfordshire, rapid progress was made, and it was in the latter area in 1935 that Lord Nuffield interested himself in the problem. Impressed with the success of the Oxfordshire scheme, foreseeing the precarious position with which the voluntary hospitals would be faced after the war, and conscious of the irreversible change in hospital administration which must emanate from the centralized wartime system of the Emergency Hospital Service, Lord Nuffield approached the Minister of Health (Dr. Walter Elliot) in November, 1939, with the proposal to create a Provincial Hospitals Trust to which he would donate one million share units in Morris Motors, Ltd. It was made clear from the beginning that Lord Nuffield had in mind a scheme of regionalization after the manner suggested by the Sankey Commission, but more comprehensive in its scope by incorporating municipal to the same extent as, and on like terms with, the voluntary hospitals. The Minister cordially approved and a Board of Trustees was appointed. The Board is charged with the double function of promoting regional and divisional councils, with financial aid at their inception, and of affording monetary aid to individual hospitals (not exclusively voluntary hospitals) through approved regional or divisional councils. To assist them in the initial stages the Trustees have embodied the Provisional Central Council, established by the British Hospitals Association, in the Provincial Hospitals Regionalization Committee of the Trust. This committee is provisional, and it is contemplated that it will consist mainly of representatives of regional councils as soon as the sixteen or seventeen of these come into being. A Medical Advisory Council has also been appointed under the chairmanship of Sir Farquhar Buzzard, who is sharing with his capable and energetic colleague Alderman W. Hyde, secretary of the Trust, a large part of the burden of setting the work on foot. This medical body, which is representative of several specialisms in medical science, is, we understand, already addressing itself to particular problems of co-operative medical work in wide areas.

The Trust, which does not transgress on the area of the King's Fund for London voluntary hospitals, has called conferences and meetings in the regions outlined by the Sankey Commission, and good progress had been made with the establishment of some of the regional and divisional councils. In other areas, however, the spirit of separatism dies hard. A minor difficulty arises in connexion with certain hospitals for limited communities whose constitutions preclude admission, by way of transfer for relief of a bigger hospital, for instance, of patients who do not belong to that community. The main obstacle, however, is the reluctance of some local authorities to co-operate, perhaps due to a suspicion that this is a deep-laid scheme on the part of voluntary hospitals to tap public financial resources and at the same time to dominate hospial policy and management. This apprehension should be dispelled. It might be worth while to reassure local authorities at once by reconstituting the provisional central committee in such a way as to give them larger representation upon it without the inevitable delay in waiting for the creation of all the regional councils, but, of course, on the understanding that the authorities or associations of authorities represented accept the principle of regionalization and are prepared to promote it.

The timely letter which the present Minister of Health, Mr. Malcolm MacDonald, has sent to Mr. Goodenough[1] reveals the same interest in the subject shown by his predecessors. He approves of the two points on which the Trust is concentrating—namely, on the one hand, building up the future hospital service on existing foundations and finding the right relation between local authorities and voluntary hospitals; and, on the other, promoting a system not constricted by existing local government boundaries. It is to be hoped that hospital authorities will take this letter as a sign that the present time is not inopportune for planning the future—a common excuse for non-cooperation. The Trust, it may be assumed, will appreciate the disinclination of the public in this country to accept any arrangement which involves bureaucratic central administration or the expenditure of public moneys by non-elective bodies. It will also be well advised to limit its operations to the hospital field and to remember that local authorities provide many medical and public health services which are not based on hospitals. On the wider topic of local government the Minister of Health has recently put the matter in these words: "No doubt there must be some changes in the organ of local government in the future. But the principle of self-government in local affairs is an essential part of our democracy; it is, indeed, a foundation of the sound democratic training and practice of a free people. It must be preserved and supported." The problem is to combine public representation with the utilization of disinterested expert knowledge and experience.

AN EPIDEMIC OF BRUCELLOSIS

Those who are proud of their powers of solving detective riddles will find their ingenuity taxed by an occurrence reported by Forest Huddlesdon and Munger[2] from the Michigan State College, East Lansing, Michigan. It appears that from December 10, 1938, to February 10, 1939, there occurred at the college forty-five clinical cases of brucellosis, of which one ended fatally. Of the forty-five patients forty-one were students, one an attendant in the animal house, one a typist, one a plumber, and one a salesman. *Brucella melitensis* was isolated from the blood of the majority, and as this organism has not been recovered from animals in Michigan for some years the source of the infection was undoubtedly a laboratory in the basement of the Institute, where work was being carried out on *Brucella*. All milk used by the students at the college was pasteurized and no evidence that it was infected was obtained. All the students, with two exceptions, had been taking courses of bacteriology during the autumn term, but no *Brucella* cultures had been handed

good for six hundred years more. But with the coming of totalitarian war local government has moved into place as one of the great fighting Services. Every town hall is a sort of military headquarters. The tasks of corporations and even of village councils have grown out of all recognition, not merely in extent but in shape. Civil defence services, the administration of air-raid shelters, hospital provision, casualty services, the evacuation of children, the reception of refugees, food control, the war-time lighting of streets, removal of debris and salvage of material, extension of police, fire, and other protective services to meet the conditions of emergency—all these have imposed immense tasks upon local government officials. In addition the normal activities have had to be continued in changed and strained circumstances—health services, education, public cleansing, housing and slum clearance, libraries, open spaces, supervision of fairs and markets, foods and drugs, electricity and gas supply, smoke abatement, welfare of the blind. During the past year there were thirteen new Acts of Parliament affecting local government, and, what are more onerous, two hundred statutory rules and orders, relating to aliens, to civil defence, to highways and road traffic, to fire brigades, and a host of other subjects.

The way in which local government officials have risen to the occasion has won general public recognition, and the late Minister of Health, in a preface to the present volume, adds his meed of praise. The *Year Book*, which with less capable editing might have been chaotic, is well arranged in nearly fifty sections, not overladen with statistics, and at the end there is a directory giving the fullest details—population, rateable value, names of councillors and officers, and every conceivably useful piece of information—relating to the sixty counties, the four hundred boroughs, the thousand urban and rural districts in England and Wales alone, not to speak of Scotland, Northern Ireland, and Eire. This great local civil service has a chronicle worthy of its pride.

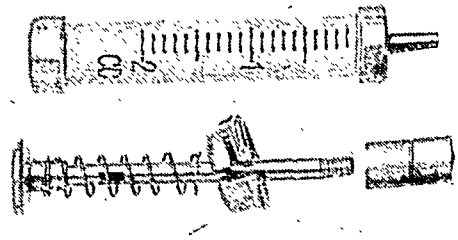
SCENES OF MEDICAL LIFE

Fingal's Box. By Harley Williams. (Pp. 382. 8s. 6d. net.) London: Jonathan Cape. 1941.

Scenes of medical life appear to have an attraction for the average reader of novels provided they unveil sufficiently the mysteries of the operating theatre and the laboratory. The medical man usually finds them pitched in too melodramatic a key, and is often exasperated by gross inaccuracies in novels by laymen. Dr. Harley Williams in *Fingal's Box* naturally avoids both these pitfalls, though we were a little surprised that his distinguished researcher stained his sections *after* they had been embedded in paraffin, and rather incredulous of the senior surgeon to a London hospital who obtained his experience in the South African War yet still thought that any surgeon should be able to carry all the instruments he required in his pocket! We also shared the polite scepticism of the hero's colleagues when he announced his cure of cancer by thyroid and pituitary extracts. But these are trifles, and the main theme of the conflicting claims of research and practice, the clash between love and duty, is attractively developed. There are vivid sketches of student life, the hooliganism accompanying an Edinburgh Rectorial election, the macabre surroundings of "midwifery on the district," and the ritual of the resident staff quarters. We hope, however, that the picture of the horrible conditions in the local infirmary of a North Midland industrial town is not drawn from life. The author's description of the tense excitement there over the League football matches adds point to the saying that in England a revolution would never be allowed if it interfered with cup ties. The story is well told and its interest actively maintained; many recognizable types of students and doctors walk through its pages, and we are left with the impression that it takes all sorts to make a medical world.

Notes on Books

Clinical Pellagra, by Prof. SEALE HARRIS of Alabama, is a work of collaboration in which ten other people have taken part. Prof. E. V. McCollum, in a brief foreword, describes it as a "philosophic treatment of clinical and experimental data of many kinds, contributed by many able workers who have contributed to the development of our knowledge of the biochemistry of nutrition and of the biologic agencies which act in conjunction with malnutritional states to undermine and pervert physiologic functions of certain types." It is not until Chapters 18 and 19 are reached that the editor-in-chief gives his description of the symptomatology and clinical manifestations of pellagra, and the general presentation lacks sequence. This book, of nearly 500 pages with many illustrations, is published by Henry Kimpton at 35s.



Principal Drugs and their Uses, by A. L. MORTON (tenth edition, Faber and Faber, Ltd., 2s. 6d.), is a pocket volume intended for the use of nurses. All drugs in common employment are listed in alphabetical order and the composition and uses of each are stated in a few lines. Inspection of the volume shows that care has been taken to keep it up to date. The number of editions through which the book has passed proves that it meets a general need.

Preparations and Appliances

SYRINGE WITH PISTON SPRING

Mr. E. LAMING EVANS, F.R.C.S. (London, W.1) writes:

The syringe illustrated, with piston spring, was manufactured by Allen and Hanburys from a pattern made for me by our instrument-maker at the Royal National Orthopaedic Hospital from a small length of a toe-upraising spring and a stock syringe. The spring is easily detachable and can be sterilized with the rest of the syringe. The syringe is assembled by unscrewing the plunger, threading the spring on the piston rod, and rescrewing the plunger.

By depressing the piston rod a negative pressure is exerted in the barrel, and the detection of fluid in vein, cold abscess, pleural cavity, or spinal theca is facilitated. I find it easy to direct the needle by holding the barrel with finger and thumb while the ring finger rests against the flattened end of the piston rod. In some syringes the end of the piston rod where it passes to the screw thread has a shoulder; if so, the diameter of the spring must be sufficient to pass easily over the shoulder on to the piston rod. It is easier to fit the barrel cap on to the piston rod before the plunger is screwed on. The principle of the spring is to make a small negative pressure in the barrel just sufficient to cause fluid to flow into it. The barrel is filled by withdrawing the plunger in the usual way. If the spring is strong enough to fill the barrel as in a dental drainage syringe, control of the piston rod is difficult and the direction of the needle into a small vein hazardous.

I hesitate to think that this simple addition to a syringe has not been suggested before; but if it has been, I have not heard of it.

VITAMIN THERAPY

THE DEFECTS OF MODERN DIET

Views on man's nutritional requirements, at one time so hotly debated, have now crystallised to such an extent that there is no longer any substantial disagreement. For example, authoritative publications [1,2,3] agree that modern diets are often seriously deficient in many respects; and they are unanimous in stressing the great importance of those "protective" food elements which are provided by fresh fruit and vegetables, wholemeal bread, milk and dairy products generally, and fish.

Unfortunately, in spite of this agreement, the day has not yet arrived when the physician can rely upon patients following general advice about "good mixed diets," simply because the ingrained habits of the population effectively prevent the more widespread use of the protective foods, quite apart from economic considerations and other practical difficulties peculiar to the times.

The Need for Supplements

Experience has shown that vitamin and mineral deficiences are almost always multiple. This makes it very desirable to use a well-balanced nutritional supplement containing, in the one preparation, the several substances with synergistic action. Vitamin D has its fullest effect when the existing calcium and phosphorus deficiencies are fully rectified. Iron is best utilised for haemoglobin formation when given with certain trace minerals and vitamin C.

Dietary restrictions, whether they are required temporarily during fever or over long periods as in the treatment of peptic ulcers—or arising through anorexia—may often prove the unwitting cause of vitamin and mineral deficiencies. The vitamins of the B group, for instance, are particularly liable to be inadequate in invalid diets. The supply of available iron, too, may be seriously curtailed when green vegetables and other sources have to be forbidden.

A supplement containing *all* the vitamins and minerals which are likely to be deficient is therefore a valuable adjunct to treatment in sickness and convalescence.

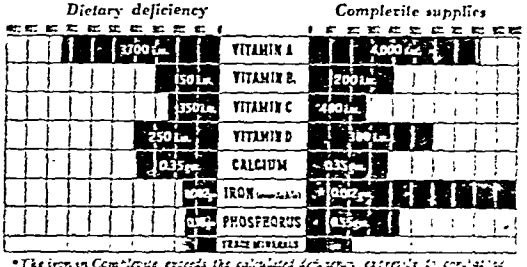
The Economies of Dietary Supplements

In cases of acute illness it is natural that the cost of the necessary remedies should not be regarded as of particular importance. But in the all too prevalent cases of dietary deficiencies, where prolonged treatment is needed, the cost of the prescription has to be considered.

There are two points with a direct bearing on this question of economics. First, as has been said, these deficiencies are almost invariably multiple; and, second, certain of the protective factors require the presence of others if they are to be fully effective. Considering these two points, the physician has hitherto been faced with the unwelcome necessity of prescribing simultaneously more than one supplement—*e.g.*, liver oil, calcium, iron, etc.—the inconvenience and total cost of which may prove an obstacle to the faithful observance of his directions.

Dental Disease and Dietary Deficiencies

If any confirmation should be needed for the now generally recognised correlation between the incidence of dental disease and dietary deficiencies, it is provided by the fact that dental caries is apt to develop rapidly in women during the period of pregnancy and lactation.



Experimentally there is a close relationship between the structure of the teeth and the supply of calcium, vitamin D and vitamin A. Dental disease and these particular dietary deficiencies are both widespread nowadays, especially among families where expenditure on food is restricted. Resistance to caries throughout life is known to be greater for teeth unharmed by deficiencies during their development. The benefits of correcting such deficiencies in children's diets are therefore not limited to those noticeable at the time. By improving the structure of the teeth—and possibly of other tissues also—they may prove of even greater value in later life.

The First Complete Vitamin and Mineral Supplement

Complevite provides, in a single preparation, vitamins A, B1, C and D with calcium, iron and phosphorus in carefully balanced proportions. The formula of Complevite is based on a careful consideration of the actual deficiencies which are found in ordinary diets; so that where dietary restrictions are unavoidable the dosage may be increased with advantage at the discretion of the physician.

Complevite affords a comprehensive nutritional supplement at a minimum cost.

It will be seen from the chart that Complevite contains all the important protective substances *in amounts carefully related to the known deficiencies.* It has, therefore, a wide field of clinical use.

*The iron in Complevite exceeds the calculated deficiency, as regards its correlation to nutritional anaemia so common in children and in women of childbearing age.

Milton treatment of wounds

This treatment proceeds by three stages:—

1. MILTON 50% SOLUTION

Thorough cleansing and mechanical removal of all infected plasma proteids, necrotic tissue and pus. Milton (up to 50% solution) dissolves this detritus and rapidly sterilises the clean surface. As a hypertonic saline it produces profuse fluid exudation.

> *"The process of mechanical cleansing is of "most advantage in wounds containing sloughs "and is well served by solutions containing "chlorine or liberating oxygen, both of which "tend to disintegrate and detach necrotic "tissue."—Lancet, May 4, 1940.★*
>
> *"The most rapidly acting antiseptics are the "halogens and those liberating nascent "oxygen."—Lancet, April 27, 1940.★*
>
> *"Profuse fluid exudation can be deliberately "produced by applying hypertonic solutions "of salt."—Lancet, May 4, 1940.★*

2. MILTON 5% SOLUTION

The clean wound is kept sterile by an isotonic antiseptic protective layer, applied by dressing, irrigation or immersion. In this mild aqueous medium a normal granulation proceeds and exudation ceases.

> *"The proper vehicle for an antiseptic to be "applied to a wound is water, and the solution "should if possible be rendered isotonic." —Lancet, May 4, 1940.★*

3. MILTON ½% SOLUTION

The Milton is then reduced to ½ per cent., at which dilution the hypochlorite has been found to actually stimulate cell-division and tissue-growth, with consequent rapid healing.

After débridement, this course of treatment is normally painless.

This therapy cannot be carried out with full success by the use of Dakin's solution or of Liq. Sod. Chlorin., owing to their causticity, their deficient saline content and to their varying strength of hypochlorite.

★ *Prevention and Treatment of Wound Infection. Action of Antiseptics on Wounds.*

Milton the Electrolytic Hypochlorite

stable, non-caustic and of standard strength (1%)

INCIDENCE OF CANCER OF THE LARYNX

Maxwell and Hogg[1] in 1933 found from a study of the Registrar-General's returns that in Great Britain between 1911 and 1930 there had been a steady increase in the mortality from cancer of the larynx, so much so that the figure for 1930 was more than double that for 1911. Moreover, the proportion of cancer of the larynx compared with the total incidence of malignant tumours had risen from 1.29 to 1.92%. In this form of cancer the mortality does not represent the true incidence of the disease, because nowadays a large proportion of cases are cured in the sense that, without evidence of its recurrence, the patients succumb years later to some other disease. In cancer of the oesophagus, where Maxwell and Hogg found a fall of from 4.05 to 3.90%, the mortality represents the incidence almost exactly, for cure of the disease in this situation is so uncommon at present as to be almost a medical curiosity. Unquestionably, therefore, the incidence of cancer in the larynx increased even more than the figures of Maxwell and Hogg indicate, even allowing for the inclusion in the figures of some cases of cancer of the epiglottis and sinus pyriformis. Chevalier Jackson and Chevalier L. Jackson[2] have undertaken a similar inquiry into the incidence of laryngeal cancer in the United States. Taking cancer of the larynx to mean cancer of the vocal cords, they have found a similarly increased incidence, both absolute and relative to other cancers. Parallel with this they have found an even higher increase in the incidence of cancer of the lung.

In the United States the statistical investigation presents certain difficulties which do not arise in Great Britain, because in 1900 the Federal surveys of vital statistics included only eleven States. The statistics therefore are available for the whole of the U.S.A. (divided into five geographical sections) only since 1930; and even now Texas is not included. If statistics over a long period are required, then only those from the States of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York, New Jersey, Michigan, Indiana, and the District of Columbia —the registration States of 1900—can be used. In these States the total deaths from cancer per 100,000 increased from 68.3 in 1900 to 120.6 in 1935. Although these figures undoubtedly show an increased incidence, account will have to be taken of such factors as more accurate diagnosis, increased longevity, more careful registration, etc. There is therefore special significance in a table quoted by the Jacksons from the Bureau of the Censor in which deaths from cancer of the larynx are compared with the total deaths from cancer throughout the years 1934 to 1938. Because this period is short and of recent date the errors mentioned are eliminated, and the figures show a steady rise from a total incidence of cancer of 134,528 with 1,100 in the larynx in 1934 (a proportion of 1 : 122) to a total of 149,214 with 1,340 in the larynx in 1938, the proportion changing to 1 : 111. Nearly all writers agree that about 90% of cases of intrinsic laryngeal cancer occur in males, and the figures from America correspond fairly well with this. A curious exception to this 10% incidence in women is mentioned by Tapia,[3] who believes that cigarette smoking is an important factor in the aetiology. In his own 993 cases there were only six female patients, and four of these were smokers. In Spain women seldom smoke, but they do so commonly in Cuba, where Herman Seguí observed thirteen cases in women among seventy-five cases, and all the thirteen were heavy smokers.

During recent years the incidence of cancer in another part of the respiratory tract—the lung—has risen even more steeply. Here again a correction is required between the difference of morbidity and mortality, for cancer is often curable in the larynx but seldom in the lung. The true increase in the incidence of these two forms of respiratory cancer must be more nearly parallel than the figures indicate. Cancer of the mouth and the pharynx does not show any increase, the American figures remaining remarkably steady for each year of the period 1934-8.

The cause of this remarkable increase of cancer in the larynx is naturally the subject of inquiry. Some years ago Dr. Chevalier Jackson[4] expressed the opinion that vocal abuse was an important aetiological factor. The Jacksons now say nothing of this, but express the opinion that alcohol and tobacco play an important part. This seems, however, to be only an opinion, and no supporting evidence is submitted. The statistics recorded by Tapia are, however, in agreement with this view, though they can scarcely be taken as scientific proof. The statistics collected by the Kennaways[5] have a more scientific basis. They noted that, according to the census figures for the twelve years from 1921 to 1931 inclusive, out of a male population of 11,916,285 there were 9,472 who died from cancer of the larynx. In the term "cancer of the larynx" they included the extrinsic form on the epiglottis, aryepiglottic folds, fossa pyriformis, and even post-cricoid carcinoma. The incidence in sixty-three occupations was noted, and the number of deaths that should occur if cancer were evenly distributed through all occupations, in proportion to the numbers employed, was compared with the actual deaths. The result was stated as a ratio of 100 registered deaths. Barmen and cellarmen easily head the list. For barmen the calculated deaths were 8.3, the actual number 39, and the ratio 469. For cellarmen the calculated deaths were 4.4, with 14 actual deaths, giving a ratio of 317. At the other end of the list come blast-furnacemen and labourers. The calculated deaths were 7.4, the actual deaths 3, the ratio 40. Gas stokers and coke-oven chargers, however, came high on the list with a ratio of 186. Whether this can be taken as proof that some occupations induce a greater liability to cancer of the larynx seems doubtful. The occupation of supplying beverages containing alcohol does not nowadays necessarily imply an excessive consumption of them though formerly it undoubtedly did. Although Tapia and the Kennaways may be cited to provide some
